When he had thus prophesied, he expired: and was succeeded by his son Evilmaluruchus, who was slain by his kinsman Neriglisares: and Neriglisares left Labassoarascus his son: and when he also had suffered death by violence, they made Nabannidochus king, being no relation to the royal family; and in his reign Cyrus took Babylon, and granted him a principality in Carmania.

And concerning the rebuilding of Babylon by Nabuchodonosor, he writes thus: It is said that from the beginning all things were water, called the sea (Thalatth?): that Belus caused this state of things to cease, and appointed to each its proper place: and he surrounded Babylon with a wall: but in process of time this wall disappeared: and Nabuchodonosor walled it in again, and it remained so with its brazen gates until the time of the Macedonian conquest.

## THE SIRIUS MYSTERY

And after other things he says: Nabuchodonosor having succeeded to the kingdom, built the walls of Babylon in a triple circuit in fifteen days; and he turned the river Armacale, a branch of the Euphrates, and the Acracanus: and above the city of Sippara he dug a receptacle for the waters, whose perimeter was forty parasangs, and whose depth was twenty cubits; and he placed gates at the entrance thereof, by opening which they irrigated the plains, and these they call Echetognomones (sluices): and he constructed dykes against the irruptions of the Erythraean sea, and built the city of Teredon against the incursions of the Arabs; and he adorned the palace with trees, calling them hanging gardens. - Euseb. Praep. Evan. lib. 10. - Euseb. Chron. 49.

Fragment of Julian the Emperor

(reigned a.d. 360-3)

From Cyril's Contra Julianum V, 176 (Migne), we have this fragment of Julian's lost work Against the Christians:

That God, however, has not cared for the Hebrews only, but rather that in His love for all nations He hath bestowed on the Hebrews nothing worth very serious attention, whereas He has given us far greater and superior gifts, consider from what will follow. The Egyptians, counting up of their own race the names of not a few sages, can also say they have had many who have followed in the steps of Hermes. I mean of the Third Hermes who used to come down to them in Egypt. The Chaldaeans also can tell of the disciples of Oannes and of Belus; and the Greeks of tens of thousands who have the Wisdom from Cheirion. For it is from him that they derived their initiation into the mysteries of nature, and their knowledge of divine things; so that indeed in comparison the Hebrews seem only to give themselves airs about their own attainments.

This translation (with some gaps supplied) may be found in G. R. S. Mead's Thrice Greatest Hermes, vol. Ill, page 199 (1964).

appendix II 257

out of a great egg whence his name, and that he was actually a man, but only seemed a fish because he was clothed in 'the skin of a sea creature'.

I am indebted to Kenneth Demarest for bringing attention to this obscure fragment from the Byzantine Patriarch Photius in his essay 'The Winged Power'. I also quote a portion of his own remarks following it:

Helladius' account is extremely valuable, the more so because it is confirmed by the extant pictorial representations of this wise being (called 'the Egg-Born') who exited in a strange suit from some kind of vessel - likened to an egg - that 'fell' into the sea. Hyginus, Manilius and Xanthus all furnish other corroborating details, speaking of gods in honor of whom the fish-form is sacred, who plunged from the sky into the waters of the Euphrates. In another variant (found in the commentary in Germanicus' edition of Aratus) the power of a holy fish pushed ashore on the banks of the Euphrates near Babylon, the 'egg' out of which the 'deity' appeared.

Before it landed in the waters, the egg-like vessel was of a luminous appearance. Thus the historian Sozomen tells us that the same type of deity descended into the Euphrates as 'a fiery star' from the sky. . . . Just as these visitant capsules in the water were remembered as 'eggs' from which higher men in fish-garb emerged, so the capsules, when they were in the sky were metaphorically described as great fiery birds or griffons ... or, again, as winged figures or deific men flying in a winged ring or capsule . . . 'Space visitors' we would call them today.

Fragment of Helladius
PRESERVED BY PHOTIUS

(C. A.D. 82O-C. 893)

PRESERVED IN THE FORM OF A SUMMARY (Codex 279)

(Helladius) recounts the story of a man named Oe who came out of the Red Sea having a fish-like body but the head, feet and arms of a man, and who taught astronomy and letters. Some accounts say that he came

## APPENDIX III

259

## APPENDIX III

Why Sixty Years?

The Sigui ceremony of the Dogon is celebrated every sixty years. What precedents for such a period of time, given religious importance, are to be found in the ancient world?

The Egyptians had such a period associated with Osiris.1 We also find the sixty-year period reduplicated by them in a manner familiar from the reduplications of the fifty-year period of Sirius B, and also in the Dogon custom of speaking of 'uniting two Sigui': 'The henti period consisted of two periods, each containing sixty years.' And this period is described in a Hymn to Osiris:2 '... most terrible is his name of "Asar" (Osiris). The duration of his existence is an eternal henti period in his name of "Un-Nefer".'

The henti period may, by pun, have had some association with the phallus, henn. I only suggest this because of the connection of circumcision with the Sigui ceremonies of the Dogon. It is pure speculation. Henti is also a title of Osiris, presumably arising from the fact that the duration of Osiris's existence is said to be 'an eternal henti period'.

My own predilection, when considering the period of sixty years, is to think in terms of a synchronization of the orbital periods of the two planets Jupiter and Saturn, for these come together in nearly sixty years. The orbital period of Jupiter is approximately twelve years and that of Saturn approximately thirty years. Five times twelve is sixty and two times thirty is also sixty. Sixty years is the great period which brings into synchronization the movements of the two great outer planets which can be seen by the eye. I have no doubt that this sixty-year period has been of considerable importance in ancient times, and the sharp-eyed Egyptians would have been well aware of it.

In speaking of the revolutions of Jupiter and Saturn, the Neoplatonist philosopher Olympiodorus has written:3 'That of Jupiter ... is effected in twelve years. And . . . that of Saturn ... is completed in thirty years. The stars, therefore, are not conjoined with each other in their revolutions except rarely. Thus, for instance, the sphere of Saturn and the sphere of Jupiter are conjoined with each other in their revolutions, in sixty years. For if the sphere of Jupiter comes from the same to the same in twelve years, but that of Saturn in thirty years, it is evident that when Jupiter has made five, Saturn will have made two revolutions: for twice thirty is sixty, and so likewise is twelve times five; so that their revolutions will be conjoined in sixty years. Souls, therefore, are punished for such like periods.'

These observations of Olympiodorus, from his Commentary on Plato's Gorgias in the form of scholia, are cited by Thomas Taylor as comment on a

passage by Apuleius (best known as author of The Golden Ass) in one of his Platonic essays:4 'For in order that the measures and revolutions of times might be known, and that the convolutions of the world might be visible, the light of the sun was enkindled; and vice versa, the opacity of night was invented, in order that animals might obtain the rest which they naturally desire. Month likewise was produced, when the moon, having completed the revolution of her orb, returns to the same place from whence she departed. And the spaces of the year were terminated when the sun had passed through the four vicissitudes of the seasons, and arrived at the same sign. And the numerations of these circulations, returning into, and proceeding from, themselves, was discovered by the exercise of the reasoning power. Nevertheless, there are certain circuits of the stars, which perpetually observe a legitimate course, but which the sagacity of men can scarcely comprehend. . . . the supreme of all of them (is that of the fixed stars) . . . the second is given to Saturn, the third to Jupiter ..." This esoteric cycle conjoining the motions of Saturn and Jupiter would have seemed of immense importance to all ancient astronomers who had a good grasp of their subject. A cycle of sixty years is so long that no single person can live long enough to verify its recurrence a second time. The knowledge of such a cycle required a continuing tradition of observation which implies a priesthood with astronomical inclinations. The discovery and verification over more than one generation of an esoteric cycle joining the two great outer planets would appear as exciting to the ancient priests as discovering DNA has been to modern biochemists. To 'crack' the mysteries of the motions

of the two outer planets is quite an achievement. No wonder, then, that the Dogon maintain that a priest who 'united two Sigui' is really rather special. Apart from the fact that no one lives 120 years very easily, and thus 'uniting two Sigui' is accepted as having celebrated two Sigui ceremonies in a lifetime, the reduplication of the cycle may be taken to signify that only by checking to see if it happens a second time can the cycle be verified. To unite two of the cycles is to achieve a henti, which we have just seen the Egyptians describe both as 120 years and as 'eternal'. How can 120 years be 'eternity'? This can be so when eternity is seen to consist of a cyclical construction. In other words, eternity is not a straight line to infinity but is rather an endless series of coils of the same size compressed into a great spring, known as time, and with the impetus of happening.

By chance, I found in an extremely obscure old book5 from early in the nineteenth century a reference to a sixty-year period in the ancient world. The book is primarily a meandering of speculations concerning Stonehenge and British stone circles. It points out that Stonehenge has sixty stones in its outer circle. Then we read: '... (this) outer circle is the oriental cycle of Vrihaspati, 6o'.6 The author later adds:7 'The great temple of Rolrich, in Oxfordshire,8 is surrounded with 60 upright stones; the cycle of Vrihaspati, an example not far distant from the others.' Later the author adds: 'the number 60 is the base of the famous cycle called the Saros of 3,600 years of the Chaldees or Culdees of Babylon . . .' and he mentions also that it is the decimal part of the 600-year cycle of the Neros period from the ancient Near East. But as for the 'famous Indian cycle of Vrihaspati', he seems upset that Indian brahmans explained it 'by saying that it arose from 5 revolutions of the planet Jupiter . . ,'"

## 260 THE SIRIUS MYSTERY

Passing beyond our quaint old source book, we may investigate this rumoured Indian cycle of Vrihaspati. We soon discover that it does indeed exist in Indian tradition, where it is more properly known as that of Brihaspati. The name Brihaspati (or Vrihaspati) is the name of the planet Jupiter in Sanskrit, and the cycle which takes its name from this planet is a 60-year cycle.

Looking further into the matter of Brihaspati, I discovered that a Brihaspaticakra has two specific meanings: the Hindu cycle of sixty years, and also 'a particular astrological diagram'. I have not been able to locate a design of this diagram. But the fact that such a diagram exists indicates to me even further that the coincidence of five orbits of Jupiter with two of Saturn may be intended here. For it is by means of a particular astrological diagram that one traditionally computes the relative positions of Saturn and Jupiter. I reproduce two such diagrams in Figures 41 and 42. These diagrams were prepared by Johannes Kepler, discoverer of our three laws of Planetary Motion, and whom I discussed slightly in Appendix I.10

In reference to these very diagrams, Santillana and von Dechend tell us in

Hamlet's Mill,11 'A "mighty conjunction" thus corresponds to the revolution of one angle or corner of the trigon of Jupiter-Saturn conjunctions - built up in sixty years (more correctly: 59.6 years) - through the whole zodiac . . .' And further: '. . . (in) Greece, where we have - besides the wrestling of Kronos and Saturn at Olympia — also the Daidalia, held in the interval of sixty years — sixty-year cycles in India, or in the West Sudan, are not likely to be understood, if the scholars prefer to inhibit the trigon of the Saturn-Jupiter conjunction . . .' And this trigon must be diagrammatically presented.

We thus see that Santillana and von Dechend specifically identify sixty-year cycles of the West Sudan, where the Dogon live, with the Jupiter-Saturn synchronism over sixty years. This was not known to me when I assumed the same thing: the reader will appreciate that such a concurrence of opinion urged me to think this idea correct.

The Dogon associate a 60-year period with the creation of the world by Amma.12 In the light of this, it is interesting that in the Western astrological tradition, Saturn 'gives the measures of creation' to Jupiter specifically through the interconnection of their orbits in the way which we have been describing. Santillana and von Dechend explain this quite well13 and Johannes Kepler's works De Stella Nova and De Vero Anno are relevant to the subject.14 See also Figures 41 and 42 for the diagrams by which Saturn gives the (temporal) measures of creation to Jupiter. There is a Great Conjunction of Jupiter and Saturn every twenty years, as the diagrams show. The Dogon seem to be aware of the 20-year subdivision of the 60-year period too. If the reader turns back to the Griaule and Dieterlen article which follows Chapter One of this book, and studies Figure ii accompanying that article, as well as the text referring to it, he will see that the Sigui 60-year computation is broken down into 20-year segments.

The act of circumcision, to the Dogon, symbolizes the orbit of Sirius B around Sirius A. It may well be, then, that such a tendency to use genital symbolism in connection with heavenly motions explains the 'castration' of Saturn by Jupiter in Greek mythology. Figure xii of the Griaule and Dieterlen article in this book records the 'mutilating domination of Sirius over the femininity

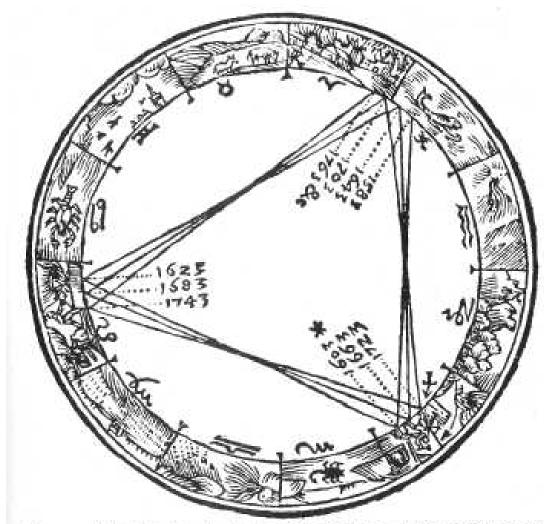

Figure 4z. A detailed illustration of the motions of the Trigon of Great Conjunctions from 1583 to 1763

of Yasigui'. In Le Renard Pale one reads a great deal about genital mutilation, castration, circumcisions, female circumcisions, and so on. These strange conceptions of genital violence associated symbolically to heavenly movements obviously came to the Dogon along with the rest of their ancient traditions, and survive as well in the Mediterranean region indigenously. The mutilation of Saturn by Jupiter, and the various creations which sprang from the resulting blood and seed, are of the same current of tradition as all the elements of a similar kind to be found among the Dogon, and which are related to these comparative orbitings of Saturn and Jupiter, as well as other heavenly bodies. The placenta comes back into the picture too. We have seen in the main text of the book that the placenta is the symbol; for the Dogon, of a planetary system, and the system of our sun and its planets is a placenta. It is therefore interesting

that the Dogon say that 60 is the count of the cosmic placenta.15 For this specifically identifies the 60 years as a count defining our planetary system,

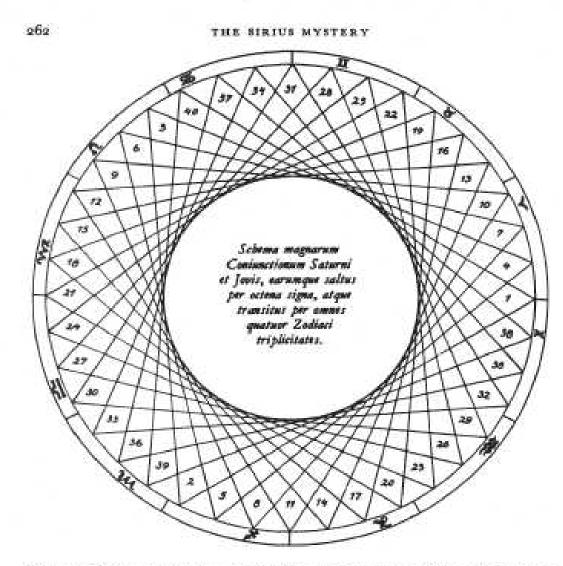

Figure 42. Scheme of the Great Conjunctions of Saturn and Jupiter, and their leap through the eighth sign and transit through all four of the triple Zodiac

and 60 years as the coordination between Saturn and Jupiter's movements can be seen as doing just that. For any system may be seen as defined by its boundaries, and as Saturn and Jupiter are recognized by the Dogon as their outermost planets for our system, their conjoinment would strictly speaking

define our cosmic placenta, our solar system, for them. The Dogon even break 60 down themselves into '5 series of 12'16 and twice thirty, which seems a fairly specific indication that our hypothesis has a sound basis. For the last point, the drawing above the door of the Dogon sanctuary of Binou17 reinforces these ideas. This drawing is used for the computation of the Sigui. Accompanying this drawing is a drawing of the Nommo which is broken down into two major portions: his right 'leg' marks the first thirty years and his left 'leg1 the second thirty years. The legs are joined to represent that only taken together do these two thirty-year periods have significance. And, as we know, Nommo did not actually have legs. He had a fish-tail extremity. The fact that each 'leg' represents

263

# appendix II

a period of years is made quite clear by the information given that 'the left leg is made a little longer every year in such a way that it is the same length as the other (leg) by the time of the Sigui.' This process recalls Plutarch's remark, noted much earlier in the book, that Zeus (Jupiter) had his legs joined together. In short, Jupiter's legs were joined together because each of his 'legs' represented one of the thirty-year orbital periods of his father Saturn, and it was on his father that he stood. For Saturn upheld Jupiter's creation by providing him with the temporal measures, as Santillana and von Dechend explain.18 And the Dogon are the people who preserve this intricate tradition most fully, which should not surprise us. They say that 60 is the 'number of the placenta', and indeed it is. Without 60 we could not define our solar system according to the traditional view of it - and this traditional view is the one resting on the capabilities of observation, which is sensible. For us to define our system today by saying it is bounded by the motions of a tiny body called Pluto doesn't mean anything to anybody. For us to ground ourselves in the weighty and ponderous motions of those two observable planets Saturn and Jupiter, and define our solar system - perhaps 'poetically' - by their motions as extremities, we would be striking a deep chord in that music of the spheres of which we have all heard fanciful tales, but of which today we know nothing. But music which cannot be heard is not necessarily lost to the inner ear. Music, after all, is not necessarily audible sound. Harmony transcends the sensibly perceptive. The observance of a celestial harmony in the ancient cultures helped keep a sane perspective. To acknowledge the deep resounding bass of the 60-year cycle was the ultimate poetic myth of the solar system, expressed in that vast mythological fabric woven around all the heavenly bodies, a whole cloth binding together both man and planets in a cosmic unity which gave man dignity and meaning in a world whose periods and cycles he had defined and celebrated in his religious festivals. Even today we do this, but have lost consciousness of it; Easter is defined by the moon. But who notices that? The cosmic bodies make their silent music but we have stopped our ears. We do not wish to be integrally related to our cosmic environment by observances of the great motions above us. All the reader need do is to take the cotton wool out of his ears and listen. He will hear silence. And the cycles and periods of that silence are the beautiful music of the cosmos. But as long as we keep our ears stopped, we will be deafened by our inner noise and will have those tortured 'modern' looks on our faces.

## APPENDIX IV

The Meaning of the E at Delphi

Plutarch wrote a fascinating essay entitled 'The E at Delphi',1 actually in the form of a dialogue, featuring Plutarch himself and several other speakers. It is to be remembered that Plutarch was a close personal friend of Clea, the Delphic priestess of his day, and he knew much and always sought to learn more about the nature and history of the oracles not only of Delphi but elsewhere as well. He was, however, most interested of all in Delphi itself, for he was one of the two priests of Apollo there.

The central subject of the discussion is the letter E which was a prominent inscription at the Delphic shrine. (That is, the letter E was carved in stone quite on its own at Delphi and was a subject of much curious speculation to the classical Greeks, who retained no tradition of the meaning of the ancient inscription of this single letter.) F. C. Babbitt, in his Introduction to the dialogue, says:2

Plutarch, in this essay on the E at Delphi, tells us that beside the well-known inscriptions at Delphi there was also a representation of the letter E, the fifth letter of the Greek alphabet. The Greek name for this letter was El, and this diphthong, in addition to being used in Plutarch's time as the name of E (which denotes the number five), is the Greek word for 'if, and also the word for the second person singular of the verb 'to be' (thou art).

In searching for an explanation of the unexplainable it is only natural that the three meanings of El ('five', 'if, 'thou art') should be examined to see if any hypothesis based on any one of them might possibly yield a rational explanation. . . . Plutarch puts forward seven possible explanations of the letter. . . . Attempts to explain the letter have been also made in modern times by Gottling . . . and by Schultz . . . Roscher . . . C. Robert . . . O. Lagercrantz . . . W. N. Bates, in the American Journal of Archaeology xxix (1925), pp. 239-46, tries to show that the E had its origin in a Minoan character E . . . later transferred to Delphi. Since the character was not understood, it, like other things at Delphi, came to be associated with Apollo. This character has been found on the old omphalos discovered in 1913 at Delphi in the temple of Apollo.

Interesting are the two coins reproduced in Imhoff-Blumer and P. Gardner, A Numismatic Commentary on Pausanius, plate X nos. xxii and xxiii (text p. 119}, which show the E suspended between the middle columns of

the temple. Learned scholars should note that the letter represented is E, not Ei: therefore such explanations as are based on the true diphthong are presumably wrong.

## 266 THE SIRIUS MYSTERY

The second explanation offered by Plutarch is in fact the correct one. This is how Plutarch suggests it:

Ammonius smiled quietly, suspecting privately that Lamprias had been indulging in a- mere opinion of his own and was fabricating history and tradition regarding a matter in which he could not be held to account. Someone else among those present said that all this was similar to the nonsense which the Chaldaean visitor had uttered a short time before: that there are seven vowels in the alphabet and seven stars that have an independent and unconstrained motion; that E is the second in order of the vowels from the beginning, and the sun the second planet after the moon, and that practically all the Greeks identify Apollo with the Sun.

The facts that Delphi is the second descending centre in the geodetic octave, and that it is symbolized by the second vowel E, would seem to go well together. The seven vowels (each corresponding to one of the oracle centres) were uttered in succession as the holy 'unspeakable' name of God by Egyptian priests. Demetrius of Phalerum, the student of Aristotle's Lyceum and who founded the famous great library of Alexandria when later in life he was exiled to Egypt, tells us in his surviving treatise On Style: 'In Egypt the priests sing hymns to the gods by uttering the seven vowels in succession, the sound of which produces as strong a musical impression on their hearers as if flute and lyre were used.'

In Chapter XVI of The White Goddess, Robert Graves discusses this too, and there quotes Demetrius. Graves also refers to an eight-letter version of the sacred name. It may be that if one wants to count the base oracle centre (which in musical analogy is the octave expression of the top centre) one should have an eight-letter version. This version of the name is:

## JEHUOVAO.

Note that E is the second letter.

We are faced with archaeological evidence that the second vowel, E, was prominently associated with the second oracle centre in descending order. (See Plate 12 of this book.) And we know from Herodotus that Dodona, the top oracle centre, was said to be founded by Egyptian priestesses from Thebes in Egypt. We also know that certain Egyptian priests sang the seven vowels (or eight vowels, including an aspirate) in succession. We have already seen

that the geodetic oracle centres seem to have an octave structure. And as this book went to press a discovery became known which demonstrated the existence of the heptatonic, diatonic musical scale in the ancient Near East. We may even make a presumption that the uttering of the seven vowels in succession may possibly have corresponded to the seven notes of the octave (but we may never know that for certain). And it is most important to emphasize that, however bizarre to us, the association of a vowel with an oracle centre is not our invention or surmise. The E may not only be read about in Plutarch but seen on ancient coins and on the omphalos stone itself (for both of which see Plate 14). And this association of the second vowel with Delphi has never been explained by anyone.

So granted all the above, what follows? If each oracle centre had a vowel

appendix IV 267

associated with it, then the second vowel being associated with the second centre would seem to imply a corresponding arrangement for the other centres. And if that is the case, it would seem that the entire system would be associated with and actually comprise a geodetic spelling-out, over eight degrees of latitude, of the unspeakable holy name of God, known commonly to the Hebrews as 'Jehovah'.

It is most important that anyone intrigued by this possibility should keep a wary eye for any further evidence. We should be on the lookout for representations of or associations of other vowels at the other centres. These may already be known to specialists in the field or there may be evidence of this sort languishing unclassified and unexplained in the basement of some museum. Or this sort of evidence may come to light at any time in the future. One place to begin looking would, it seems to me, be with an examination of the omphalos stone from Delos, which is to be seen in Plate 12 of this book. Does this omphalos stone have a single letter inscribed on it similarly to the Delphi omphalos stone? And what of all the other omphalos stones, such as the one from Thebes in Egypt (see Plate 12). Are any of these well enough preserved to show a puzzling single hieroglyph of a vowel? I have not carried out any investigation of this sort myself at the present time.

In closing, it would seem that the E at Delphi must fall into some coherent system of the kind I suggest, and the explanation of the enigma must be connected with Plutarch's lightly advocated second explanation - that to do with E being the second vowel. (Babbitt's exclusion of the diphthong on the basis of the ancient coins to be seen in Plate 14 of this book is therefore crucial and to my view conclusive.)

## Notes

1. The dialogue 'The E at Delphi' is to be found in English in Volume V of Plutarch's Moralia (altogether 15 vols) published in the Loeb Classical Library series; London: William

Heinemann Ltd., and U.S.A.: Harvard University Press. The volume first appeared in 1936, and the translation is by Frank Cole Babbitt. Other works of Plutarch in the same volume are 'Isis and Osiris', "The Oracles at Delphi No Longer Given in Verse', and 'The Obsolescence of Oracles'.

2. Ibid. See Plate 14 of this book.

## APPENDIX V

Why the Hittites were at Hebron in Palestine

We read in Genesis 23:7 that 'Abraham stood up and then bowed low to the Hittites, the people of that country'. The only trouble about this is that, according to our extremely sound archaeological knowledge, there should not have been any Hittites in 'that country' - namely, at Hebron in Palestine. The Hittite conquests never extended that far south. So what do we do with this riddle?

In his book The Hittites, Professor Oliver Gurney has an entire section (pp. 59-62) entitled 'The Hittites in Palestine'. In it he says:

We have now to deal with the paradoxical fact that, whereas the Hittites appear in the Old Testament as a Palestinian tribe, increasing knowledge of the history of the ancient people of Hatti has led us ever farther from Palestine, until their homeland has been discovered in the heart of the Anatolian plateau. Moreover, the preceding outline of Hittite history will have shown us that before the reign of Suppiluliumas there was no Hittite state south of the Taurus; that the Syrian vassal states of the Hittite Empire were confined to the area north of Kadesh on the Orontes; and that although Hittite armies reached Damascus, they never entered Palestine itself. Of the neo-Hittite states there was none south of Hamath, and the latter did not include any part of Palestine within its territories, being separated from it by the Aramean kingdom of Damascus.

The presence of Hittites in Palestine before the Israelite conquest thus presents a curious problem. So far from explaining it, all our accumulated knowledge of the people of Hatti [the Hittites] has only made it more perplexing.

References in the Bible include Genesis 23 (entire), Genesis 26:9-11, 34-5; 27:46 (where Rebecca says to Isaac: 'I am weary to death of Hittite women! If Jacob marries a Hittite woman like those who live here, my life will not be worth living!'), and 36:1-3. Further crucial reference to the Hittites appears in the Book of Numbers 13:29. There Moses is told by some men he had sent at the Lord's command to explore Hebron (and we are told in Numbers 13:22-3, that Hebron 'was built seven years before Zoan in Egypt' - which is a

curious remark, implying a connection between Hebron and Egypt and also that there was something special at Hebron which could be described as 'built'), that at Hebron they had seen the Hittites.

We thus find clear evidence in books of the Bible for the Hittites residing in Palestine. And their settlements were specifically in the hills at Hebron.

\_

#### APPENDIX V

269

Gurney says: 'Who, then, were these Hittites of the Palestine hills? A very ingenious answer has been put foward by E. Forrer.' The gist of this is that, considerably before 1335 B.C., some Hittites from the city of Kurustamma in the north-east of Anatolia had gone to Egypt, of which documentary evidence exists:

However surprising it may seem, the text here quoted states explicitly that during the reign of Suppiluliumas some men from this obscure northern city entered the 'land of Egypt', a term which would include all territory under Egyptian rule. The text leaves the circumstances under which this occurred obscure, but the reference to the Weather-god of Hatti as the instigator of the move is in favour of a deliberate act of state rather than a flight of fugitives from the Hittite conquest, as suggested by Forrer. However that may be, we have here one certain instance of a group of Hittites (i.e., subjects of the King of Hatti) entering Egyptian territory, and the possibility of their having settled in the sparsely populated Palestinian hills is not to be ignored . . . (But) emigration of Anatolian Hittites to Palestine cannot have been a frequent occurrence. . . . . (and) there is some hope that further excavation [of texts] among the archives of Boghazkoy will bring enlightenment.

It should be pointed out that the reign of Suppiluliumas during which the above emigration took place covered the years 1380-1346 B.C. It was to him that the widow of Tutankhamen, the Egyptian Queen Ankhesenamun, third daughter of Pharaoh Akhenaten, sent a plaintive letter asking for one of his sons to become her husband. He sent a son, but the son was ambushed on the way to Egypt and killed, probably by Hor-em-heb, who seized the throne of Egypt and forced Ankhesenamun to marry him in order to legitimize his usurpation. This is a sad story but does not really concern us here. I mention it merely to bring to life the chronology of the emigration to Hebron, and also because it demonstrates the close links possible at that time between the Hittites and Egypt. Those who wish to read the letter in full and follow up this interesting tale of personal tragedy are referred to Ancient Mar Eastern Texts (ed. Pritchard, see Bibliography), pp. 319, 395.

However, the Hittite emigration in the reign of Suppiluliumas cannot have been the original Hittite settlement at Hebron. For if Abraham met Hittites

when he arrived at Hebron, then there must have been Hittites there for several hundred years before the reign of Suppiluliumas which extended 1380-1346 B.C. We learn from George Roux in his book Ancient Iraq, p. 242: 'Abraham and his family came from Ur in Sumer to Hebron in Canaan, probably about 1850 B.C., and there are good reasons for placing Joseph's migration to Egypt during the Hyksos period (1700-1580 B.C.).' Despite the fact that there can be a case made for Abraham's Ur being a different Ur, the main point is the date, for Abraham went to Hebron and met Hittites already there five hundred years before the emigration which Gurney mentions. Roux repeats his dating, and gives references, on page 215 of his book.

It is likely that, half a millennium after Abraham, the Hittite emigration of which we have proof during the reign of Suppiluliumas went to Egyptian territory, and quite probably to Hebron, to reinforce the Hittite community

270

APPENDIX V

271

which had already been there for many centuries, but which was facing hard times. One has only to read the Amarna Letters in translation in Ancient Near Eastern Texts - vivid, compulsive, desperate documents - to know the anarchy into which the region of Palestine was plunged during this period. The prince of the Hebron region, Shuwardata, first fought the rapacious Apiru raiders who swarmed over the countryside and then joined them, rebelling against the Pharaoh before whom, in his correspondence, he had shortly before been 'bowing seven times and again seven times, both prone and supine'. But Egypt was weak, and Palestine degenerated into chaos. It is no wonder that during this period there was a Hittite migration to what was titular Egyptian territory. No Hittite settlement at Hebron could have felt itself entirely secure. But what was the reason for the Hittite settlement at Hebron in the first place?

In the light of our earlier elucidation of the geodetic oracle octaves, it seems clear that the presence of the Hittites at Hebron can be explained on religious grounds. For we know that Hebron was the 'base oracle' centre of the eastern geodetic oracle octave. The top centre of this same octave was Metsamor at Ararat, to the north and east of Hittite territory, and is probably the reason why the Hittites who migrated to 'Egyptian territory' during the reign of Suppiluliumas were from an obscure north-eastern city (because this was the closest Hittite region to Ararat). The area of Ararat was later to become the kingdom of Urartu, and we know that this kingdom and the Hittites were not altogether strangers, for we learn from Gurney, pages 44-5: 'The North Syrian

Hittite states . . . may have felt a certain racial or cultural affinity with Urartu

Since we have documentary evidence that it was a divine command which made the Hittites of the fourteenth century B.C. go to what we assume was possibly Hebron, we can see that they were obeying an oracular injunction. This is natural if their activity was connected with the oracle centres. Indeed, they could not have gone without a divine command on such exclusively divine and non-imperial business. Gurney may be quite right in saying that the journey was a deliberate act and not a flight of fugitives. It was as deliberate as the 'doves who flew to Dodona'.

We have distinct evidence that Hebron really did have an oracle centre, apart from its being on the same latitude as Behdet. To investigate this, we turn to The White Goddess by Robert Graves, where in Chapter IX he discusses Hebron a great deal.

But Caleb . . . conveyed the Holy Spirit to Hebron when, in the time of Joshua, he ousted the Anakim from the shrine of Machpelah. Machpelah, an oracular cave cut from the rock, was the sepulchre of Abraham, and Caleb went there to consult his shade ... it is likely that neither Isaac nor Jacob nor their 'wives' were at first associated with the cave. The story of its purchase from Ephron . . . and the . . . Hittites, is told in Genesis 23. Though late and much edited, this chapter seems to record a friendly arrangement between the devotees of the goddess Sarah, the Goddess of the tribe of Isaac, and their allies the devotees of the Goddess Heth (Hathor? Tethys?) who owned the shrine: Sarah was forced out of Be'er-Lahai-Roi by another tribe and came to seek an asylum at nearby Hebron (p. 162).

Graves states (p. 164) that 'Abraham' was in fact a tribe, and that this tribe also came down from Armenia (vicinity of Ararat). He says: "Abraham" being in this sense the far-travelled tribe that came down into Palestine from Armenia at the close of the third millennium B.C.' In fact, we must give some thought to 'the chosen people' - later known as Hebrews - being 'chosen' in the sense that they were particularly connected with tending an oracle centre or centres. Did Abraham go to Hebron for the same reasons that the Hittites did?

Graves says (p. 164):

J. N. Schofield in his Historical Background to the Bible notes that to this day the people of Hebron have not forgiven David for moving his capital to Jerusalem ('Holy Salem') which they refer to as 'The New Jerusalem' as though Hebron were the authentic one. There is a record in the Talmud of a heretical sect of Jews, called Melchizedekians, who frequented Hebron to worship the body (consult the spirit?) of Adam which was buried in the cave of Machpelah.

In fact, these Melchizedekians, though considered heretics, may have been adherents of a purer undistorted form of worship. And it may be that David was the great perverter of Judaism by moving Holy Salem away from Hebron. Graves continues:

For Adam, 'the red man', seems to have been the original oracular hero of Machpelah; it is likely that Caleb consulted his shade not Abraham's, unless Adam and Abraham are titles of the same hero. Elias Levita, the fifteenth-century Hebrew commentator, records the tradition that the teraphim which Rachel stole from her father Laban were mummified oracular heads and that the head of Adam was among them. If he was right, the Genesis narrative refers to a seizure of the oracular shrine of Hebron by Saul's Benjaminites from the Calebites.

Caleb was an Edomite clan; which suggests the identification of Edom with Adam: they are the same word, meaning 'red'. But if Adam was really Edom, one would expect to find a tradition that the head of Esau, the ancestor of the Edomites, was also buried at Hebron; and this is, in fact, supplied by the Talmud . . . that Esau's body was carried off for burial on Mount Seir by his sons; and that his head was buried at Hebron by Joseph.

Elsewhere (page 167) Graves says:

It is possible that though the Calebites interpreted 'Adam' as the Semitic word Edom ('red') the original hero at Hebron was the Danaan Adamos or Adamastos, 'the Unconquerable', or 'the Inexorable', a Homeric epithet of Hades, borrowed from the Death Goddess his mother.

Graves says that according to the tradition (p. 161): 'Hebron may be called the centre of the earth, from its position near the junction of two seas and the three ancient continents.' How similar this 'centre of the earth' epithet is to Delphi's, as 'the navel of the world'. All the main oracle centres were navel or omphalos centres of (he earth. Hebron's description as such is what one would

## THE SIRIUS MYSTERY

have predicted. The traditions of the creation of Adam at Hebron and of its being the site of the Garden of Eden, as Graves tells us in this chapter, make sense also when it is realized that Hebron was the base of the entire eastern geodetic octave of oracle centres. It was the eastern counterpart of Behdet itself.

Graves tells us at the beginning of Chapter Four of the later history of Hebron:

A confederacy of mercantile tribes, called in Egypt, 'the People of the Sea' . . . invaded Syria and Canaan, among them the Philistines, who captured the shrine of Hebron in southern Judea from the Edomite clan of Caleb; but the Calebites ('Dog-men'), allies of the Israelite tribe of Judah, recovered it about the same time. These borrowings were later harmonized in the Pentateuch with a body of Semitic, Indo-European and Asianic myth which composed the religious traditions of the mixed Israelite confederacy.

In closing, we should note with a minimum of surprise, that the guardian tribe of the shrine of Hebron, the Calebites, were 'Dog-men'. Dogs are guardians, and preserve the secrets of the Dog Star Sirius, particularly as expressed in the ancient geodetic oracle octaves.

As for the Hittites, they were at Hebron - and only at that specific place in Palestine - because of its oracle centre. That is why they were 'sent by divine command', centuries later, presumably to reinforce that very place against the dangers of a turbulent time when Egyptian control under Akhenaten had collapsed.

## APPENDIX VI

The Dogon Stages of Initiation

The following description of the Dogon system of graduated initiation into the mysteries of tribal religion is taken from Le Renard Pale (The Pale Fox) by Marcel Griaule and Germaine Dieterlen:

The Dogon, who have classified everything, have established a layered hierarchy of their teachings they give to the initiates. Their knowledge is staggered in four degrees, that are, in the order of their importance, the giri so, the benne so, the bolo so, and the so dayi.

The giri so, 'word at face value', is the first knowledge implying simple explanations where the mythical characters are often disguised, their adventures simplified and invented, and are not linked together. It has to do with invisible deeds, concerning the ordinary rituals and materials.

The benne so, 'word on the side', includes 'the words in the giri so' and a thorough study of certain parts of the rites and representations. Their coordination only appears within the great divisions of learning which are not completely revealed.

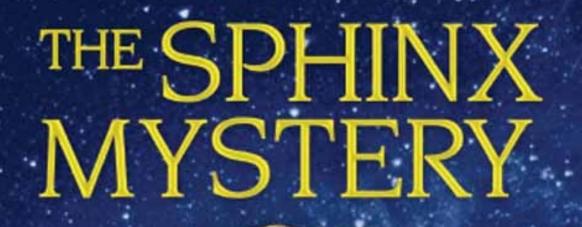

The bolo so, 'word from behind', completes the preceding learning, on the one hand, and on the other hand furnishes the syntheses that apply to a vaster whole. However, this stage does not yet include instruction in the truly secret parts of the tradition.

The so dayi, 'clear word', concerns the edifice of knowledge in its ordered

complexity.

But initiation is not merely an accumulation of learning, nor even a philosophy, nor a way of thinking. It has an educational character, for it forms the individual, moulds him, as he assimilates the knowledge it imparts. It is more than that, because of its vital character; as it makes him understand the structure and system of the universe, it brings the initiate progressively towards a way of life which is as aware and complete as possible within his society, in the world, as he was conceived and created by God.

... Thus, a 'fourth dimension' is introduced into the life of the Dogon, peculiar to the myth and symbol which is as necessary to their existence as food and drink, in which they move with ease and flexibility, but also with the deep sense of the immanent presence of the invisible thing they are invoking ... at a given moment, for such and such a ceremony, they know to what sequence of the myth and to which connections (their) act belongs ...

# The Sphinx Mystery

"Brilliant! A remarkable work of detailed and painstaking research, integrative thinking, and original insight. The Temples' reinterpretation of some Egypt's abiding mysteries is more than thought-provoking: it is inspiring."

RUPERT SHELDRAKE, Ph.D., AUTHOR OF *THE PRESENCE OF THE PAST* 

"I was swept straight into this marvelous book. It's brilliant, original, occasionally delightfully malicious, and it showed me just how little I really knew about the Sphinx."

COLIN WILSON, AUTHOR OF ATLANTIS AND THE KINGDOM OF NEANDERTHALS AND THE OUTSIDER

### **ACKNOWLEDGMENTS**

We would like to thank Inner Traditions for their enthusiasm for this book and for their excellent work on its preparation and publication. In particular, we would like to thank Ehud Sperling, whose passion for ancient Egypt has continued unabated over the years and whose achievements as a publisher of esoteric and meaningful books for the English-speaking world has done so much to keep the spirit alive for the public in these days of rank commercialism and banality. Thanks also to Jon Graham for inspired work in the field of acquisitions, Jeanie Levitan for her competence as managing editor, Chanc VanWinkle as tireless project editor, Judy Stein and Elaine Cissi as sharp-eyed copy editors, Peri Ann Swan for the cover design, and Jon Desautels for the interior design and layout.

Daud Sutton's three wonderful drawings have been a magnificent contribution to the book, and we are all the more grateful in that they were given to us as a gesture of friendship, prepared with infinite patience during his busy schedule.

Michael Lee's tireless and cheerful contributions to the scanning, filing, archiving, and above all the meticulous cleaning of images have been peerless and crucial to the management of such a large number of illustrations as are found in this book.

Stefano Greco has been a good friend and determined researcher into the mysteries of the lost papers of Giambattista Caviglia in Italy, and in the course of this he discovered the unknown treatise of Annibale Brandi, which he has translated as an appendix for this book. Without his efforts, this priceless addition to our knowledge of the early excavation of the Sphinx would have remained unknown forever.

Eleonore Reed contributed so much of her time and energy toward assisting with translating the difficult article by Ludwig Borchardt that appears as an appendix to this book, and her friendship and efforts are greatly appreciated.

We wish to thank Mohamed Nazmy and his colleagues at Quest Travel for their extensive assistance in Egypt.

We wish to thank Robert and Rieki Rubinstein of Amsterdam for making possible the translation of the Dutch text of Edward Melton in part 2.

We are grateful to Terence du Quesne for materials and discussion about Anubis, a subject on which he is a leading expert in the field.

We wish to thank also Tom Rees for generously helping to understand some of the most obscure eighteenth-century French words and phrases, Ian Burlingham for his help with legal agreements, Professor Ioannis Liritzis for assisting with the inclinometer reading and other observations at the Sphinx Temple, and Professor Lal Gauri for answering numerous questions about his work on the Sphinx and about the limestone structure of the Giza Plateau.

Finally, we want to thank all our friends in England, whom we have neglected shamefully while

#### About the Illustrations

All the illustrations in this book are presented as duotones to capture the flavor of the Egyptian landscape and to preserve the original reproduction quality of many of the historic photographs. We have framed these rare historic images in black to clearly separate them visually from the more modern photographs and the diagrams that comprise this book.

All the photographs originally taken in color may be seen in full color on the book's website, <a href="https://www.sphinxmystery.info">www.sphinxmystery.info</a>, where other supplementary material and information is also available. The website is intended for use as a complement to the book, and though it does not accept e-mails or host discussion, we hope readers will find it a valuable, and graphically rich, information resource.

### INTRODUCTION

#### **OLIVIA TEMPLE**

O Behold, I pass near you, I have placed Anubis as your guardian, I give you light.

THE VOICE OF THE SUN IN THE ANCIENT EGYPTIAN TEXT

THE BOOK OF CAVERNS

I am not alone in dividing my life into two, an equivalent to BC and AD, which in my case is Before Egypt and After Egypt. Most people who spend time among the ancient places there find it becomes harder subsequently to visualize how life was *before* . . .

Since my first trip to Egypt many years ago, the meaning of life has become clearer. Questions and doubts, fears and shadows, have become mysteriously clarified as if I have suddenly found the key to a complicated coded message.

The most striking thing among the many that the ancient Egyptian world has revealed to me is that there was no word in their language for religion. It is only when you think about this for some time and have those words as a mantra in your subconscious as you explore the temples and tombs in Egypt that the enormity of this fact takes shape. Your own thought processes, the very foundations of your own culture and spirituality, are not so much questioned as reprogrammed. This brings to mind John Lennon's song *Imagine:* "Imagine there's no heaven . . . and no religion too . . ." All the things we imagined are suddenly not quite what they seem. One must always be aware of the fact that it was the afterlife that was the important part of life to the ancient Egyptians. Life itself was a big buildup and preparation for the ethereal journey to the otherworld. The ultimate goal was to become an *akh*, or immortal glorified spirit. One's mortal life was only to prepare for this end. So in some ways it simulates the Christian faith: we live on Earth as good citizens, acknowledging the divine and hoping after death to go to heaven.

In Egypt, it feels right to hail the symbolic power of the individual animal-headed gods who are so mysteriously carved onto the walls and crypts and painted on the ceilings and in the temples—a pagan worship, a giving thanks, and an awe of the skyward journey that brings the stars and sunbeams down to Earth. Not one almighty and vengeful God but many minor deities, each one vital in contributing to the whole, the Cosmic Order.

So, when we spent time, lots of time, on the Giza Plateau, wandering around for hours above- and belowground, in the Valley and Sphinx Temples, the Osiris Shaft, the Great Pyramid at night, and the

Sphinx precincts, examining almost every stone and every inch, a new ray of recognition pierced our souls. Everyone who knows this place, who spends more than a casual amount of time in the sacred places of the ancient Egyptians, experiences a defining moment, an alchemical change, that creeps into your psyche like a drug.

Everyone has seen pictures of the Sphinx and the pyramids since childhood; they are stamped indelibly onto our memory bank. So, it was a big shock meeting the Sphinx face-to-face, walking the length of its scaffolding-clad body, seeing how deep down it sits in the sand, as if in a pit, and how it seems to smile graciously, offering up its secret if anyone will listen . . . Shhhh! . . . I am Anubis, can't you see? Oh! I see! The Sphinx is Anubis! Can't you see? That Mona Lisa smile, the elongated and huge body, the long front legs ready to spring into action when the starter gun pops, the strata stripes and weather-worn sides of the pit in which it sits, the solid hulk, marooned in the sand like a beached whale. There is a sense of water here, you can almost hear it; yes, the Sphinx has known a watery past.

Later, back in England, immersed in the early travelers' tales, when Cairo across the river was two hours from the pyramids along a palm-fringed lane, the water surrounding the Sphinx, the sense of it being an island with Anubis the Guardian, became more and more apparent.

For nearly two millennia, only the neck and head of the Sphinx were visible above the sand, with a vague spinal shape trailing behind it. There was no leonine creature, no Sphinx Temple, Valley Temple, or Chephren Causeway. Although Pliny describes the Sphinx in the first century AD, when it had been excavated and cleared of sand, as a burial place for a king, and the legend of a secret chamber was born, the desert sands did not take long to cover the colossus again. By the time of Napoleon's expedition in 1798, it was, once again, only the head and neck that showed above the ground. Time after time, excavators had unearthed the Sphinx, and time and again the sands drew a veil over it. When you walk or drive out into the deserts of Egypt it is quite a shock to discover how hilly and undulating, how everchanging it is, shifting and stirring endlessly like a restless windblown ocean. Upon this furrowed surface you can find small pieces of petrified wood and occasionally a bit of iron from outer space. I saw a vivid mirage there on one of those long hot walks, a shimmering lake, complete with palm trees . . . illusion is never far from reality, and perhaps beyond was the Egyptian Eternity.

Before the hieroglyphs, before the mystifying and tantalizingly beautiful decorations of the temples etched with perfect exactitude and colored with rich pigments, before the high decoration of the Fifth Dynasty with its Pyramid Texts written on walls, the Sphinx was there, guardian, god, long before Jesus walked the earth. Our attempt at uncovering the mysteries of the Sphinx is perhaps only the beginning, and it will be for others who come after us to follow the trail and find more signs. But it is as if the Sphinx itself coauthors our offering, for he too wants his past to be revealed. He is our third collaborator, and no matter how many modern slabs of limestone cover him up and hide his origins, the Sphinx "Anubis" will continue to be the *ba*, or spiritual force that forever guards the pyramids.

From now on, O living matter, you are no more Than a lump of granite surrounded by a veil of terror, Dozing beneath the hazy Saharan sands. An ancient Sphinx unknown to the heedless world, Unmarked on the map, whose timid smile lights up Only when the sun goes down. In the evening she leads him to the graves of the elders in the tradition of Lamenting, to the sibyls and the prophets. But night comes on, so they go along more slowly, and soon rising upwards and moonlit, stands he who watches over all the funerary monuments. Brother to that of the Nile, the sublime Sphinx—: for the sealed chamber, a Countenance.

And they shudder at the kingly bedecked head, which for all time, in silence, lays the human visage upon the scale balance of the stars.

RAINER MARIA RILKE, TENTH DUINO ELEGY (71-80)
TRANSLATED BY ROBERT TEMPLE

## INTRODUCTION

#### ROBERT TEMPLE

The most important conclusion to be drawn from the strange odyssey of this book is that the Sphinx is not what we think it is. When Olivia and I first stood and looked at the Sphinx we both felt there was something wrong with it. Why was the head so ludicrously tiny? Why was the back flat? We thought it was supposed to be a lion, but that was no lion. And what was it doing down in that pit? Nothing seemed right, and it made us uncomfortable.

One of the things that most disturbs me is the phenomenon known as "consensus reality." That is what we all agree to believe. Often it is incorrect, but we go on believing it anyway, because we are too lazy to alter our views. Most people like to follow the line of least resistance in life, which means not having to bother to think too much. Thinking is wearisome, takes time and energy, and we have too little of both. So why not let somebody else do this painful task for us? Hence the popularity of "secondhand thinking," whereby we plug our brains into some remote service provider, like connecting our computers to the Internet, and allow other people's ideas to flood in and become our own. So easy! So convenient! Fast, clean, and efficient! Who needs to think of an idea when you can get an idea anytime from somewhere else and just click on "accept all changes" and it's done?

But I never accept anything unconditionally. I have to verify everything. If people say the light is switched off, I check anyway. If they say the sky is blue, I check. It might be gray; who knows? One reason why I do not believe that anyone is ever correct is that I do not believe it is possible to be correct. I certainly don't hold any of my opinions with certainty. I look upon *certainty* as a condition of the human species and precisely what is wrong with us. Everybody is certain, they are certain about this, certain about that. But they are all wrong. I refuse to be certain about anything. That is why I challenge conventional notions. I object to both the word *conventional* and the word *notion*.

So that is why I did not accept the Sphinx when I first saw it.

Having rejected the accepted consensus view of the Sphinx at first sight, we then had the problem of deciding what to do about it. If it wasn't what everybody knows, then what was it?

That's what this book is all about.

The first thing that seemed certain was that the Sphinx, whatever it was, was not a lion with a man's head. The second thing that seemed certain was that the head was not original, because it was out of proportion. Several people, I later discovered, had mentioned this over the years, and suggestions that the head had been recarved were not new, although they were still a minority opinion. The disproportionate size of the body to the head could not be seen prior to the excavation of the Sphinx in 1926, so that is why there were no earlier suggestions of the recarving of the head.

Those were good things to start with.

Then there was the question, which had nothing to do with what we were seeing, of whether there was a secret chamber under the Sphinx. This was a subject of feverish interest already, discussed in many popular books and articles and contemptuously rejected in various scholarly books and articles. From previous experience, I suspected that probably neither argument was right. In most cases where people argue violently with one another, they are all wrong.

And then yet again, there was the subject of "ancient rain." It was supposed to have rained at the Sphinx 12,500 years ago, various enthusiastic popular authors (all of whom I knew personally) insisted. That was where all the strange signs of what looked like water erosion came from. However, I knew enough about archaeology to know this wasn't possible, because it meant that seven thousand years or more of archaeological remains were missing. You can't just not have anything in the ground, because there is always something in the ground. So it had to be wrong. But clearly there was water erosion, and it is easy to see. So what was the answer to that, then?

There were plenty of enigmas to try and solve!

I have to admit that it has all been great fun. It has been a lot of hard work, but then nothing is fun if it is too easy. Sometimes I tell people I have been inside the Sphinx, and they think I am joking. Sometimes I tell them the Sphinx is not a lion with a man's head at all, and they think I am joking. Sometimes I tell them that the Sphinx once was a giant statue of Anubis, crouching as a guardian of the sacred necropolis at its entrance. They look surprised for a moment, and then they readily agree with me. Most people think it is obvious "once you think about it." And so our job was to think about it, so that everybody can see just how obvious it is. Take a look at figure 5.11, and you will see what I mean.

This book has benefited from our special access to the Sphinx and the Valley Temples in front of the Sphinx, which was made possible because we were given permission by the Egyptian Supreme Council of Antiquities, along with a colleague from Greece, to do intensive studies of those two structures in connection with a dating project. As a result, I was able to make some fundamental observations relating to the Sphinx that would otherwise have been impossible. One study was the result of an idea I had while we were standing for hours on the floor of the Sphinx Temple (which is normally closed to all visitors). In a moment between other activities, I took a sighting with an inclinometer we happened to have with us, and the result was most astonishing; I describe it later on.

But the most important thing that resulted from that special access was something that I did not appreciate at the time at all. Because, as I described earlier, I always like to check everything personally, and I am so thorough about detail that everyone who is with me is exasperated by it, I meticulously took a very large number of photos of the passage between the two temples and especially of the base of the north wall of the Valley Temple. My attitude was "you never know when something is going to be useful one day." So I took a long series of photos of what most people would think was just a boring stone wall of no interest whatsoever. I had no idea at the time of the importance of the results. The wall was so uninteresting and unremarkable, in fact, that neither of the two excavators of the Sphinx Temple (Hassan and Ricke) nor the excavator of the Valley Temple (Hölscher) bothered to mention anything about it in their publications. In fact, there is no evidence they ever even bothered to look at it except in passing.

It later turned out that this series of photos of a stone wall, which no one else had ever looked at twice, was crucial evidence to support an astonishing conclusion about the Sphinx. These photos are all reproduced here, because as all the features shown in them have now been covered over with modern restoration stones and cement, they are the only surviving evidence.

Before a person can understand anything, he or she should study everything anybody else has ever said about it first. So we set about systematically collecting every account of the Sphinx since the first known

one, by the Roman author Pliny in the first century AD. By the time we got to the year 1837 we were overcome by exhaustion and had to stop, as they were beginning to drown us. Most of the accounts were not in English, so those all had to be translated. Olivia translated all the French ones, I translated the German ones, and friends Robert and Reiki Rubinstein did the Dutch one. We did not collect every Arabic account, but we translated into English those Arabic accounts that had already been translated into French.

As a result of studying the early accounts of the Sphinx, I made the surprising discovery reported in chapter 3 of the survival of specific information through folklore for three thousand years, or seventy-five human generations! This in itself is a major insight into how information can survive without total degradation and loss of message across a length of time bordering on the inconceivable. If I had discovered nothing else, I would be proud of having brought that to light.

We are left now with a totally different Sphinx than the one with which we started. We started with a lion and we got a dog; we started with the face of either Cheops or Chephren and we got another pharaoh's face altogether, whom I have been able to identify precisely. We started with a dry Sphinx and we got a wet one. We started with a Sphinx that was not mentioned at all in the most ancient texts, the Pyramid Texts, and we ended with a Sphinx that was mentioned a great deal in the Pyramid Texts in the most specific way, even saying that it stood beside a causeway at Giza. We started with a Sphinx with nothing inside and we got an interior tunnel. We started with a Sphinx with no secret chamber and we got 281 years' worth of published eyewitness reports of the secret chamber beneath the Sphinx by people who even gave us its measurements and its precise location beneath the statue.

We have a new Sphinx now. Long live the Sphinx!

## A Note on the Use of Egyptian Words in this Book

The linguistic symbols used by Egyptologists to transliterate Egyptian words and names have not been used anywhere in this book, *including in quotations*, where we have spelled out whole words in common English spellings to facilitate the reading of these words and names. We hope that the quoted authors concerned will understand that we are trying to make their comments available to a wider public readership.

When Egyptological authors publish their works, they generally use hieroglyphs and other linguistic symbols or complex transliterations. The following passage that I have been translating from a text originally published in German by Erik Hornung is an example of Egyptian transliteration that uses recognizable letters but is nonetheless no more comprehensible for that.

"... the *jpwt nt wnt nt Dhutj*... are from any point of view a mystery... King Cheops demands that Djedi fetches the *jpwt* for him, and moreover they are—an unknown number—inside a box of stone. Throughout, however, *jdt* seems to signify a box or chest... the mysterious box is described inside the secret chamber, so as in the Papyrus Westcar as a *fdt* in an 't; but this box does not contain a *jpwt*..."

The situation gets even worse when linguistic symbols other than normal letters (such as hryw šsr.w=sn<sup>h</sup> ssm=sn hfty.w R<sup>c</sup> m-ht is 'p=f hr=sn) are mixed in, as they always are. The use of these linguistic symbols or strings of consonants without vowels is intended to let professional readers know that the author is adhering to strict accuracy in transliteration. However, we have the responsibility of communicating with the general public, and having made this advance disclaimer, we hope that no misunderstandings will arise, or that any Egyptologist will in any way be blamed for our decision.

We have not bothered indicating these changes with brackets in order to avoid cluttering the content of the excerpted material. Anyone interested in seeing the original quoted excerpts will find source references in the notes or at the beginnings of the excerpts in part 2 and the appendices.

### SPHINX OBSESSION

The Sphinx and the pyramids are the central attractions in Egypt. All tourists who visit Egypt go to Giza to see them (see figure 1.1). And we know they have always done so, for Greek and Roman graffiti have been found there in profusion. After Egypt opened up for the first time to foreigners in the sixth century BC, the Greeks poured in and arrived in such numbers that the Egyptian kings had to try to restrict them to special cities of their own on the Mediterranean coast. This was only partially successful. Eventually the Greeks ended up ruling Egypt under the Greek dynasty known as the Ptolemies. After the death of Cleopatra, who was the last Ptolemaic queen, rule of Egypt passed to Rome. And Roman tourists then arrived over many centuries in countless thousands.

The Sphinx is not mentioned by the Greeks in any surviving writing, presumably because it was covered in sand up to the neck, and the head alone could not readily be seen from the vicinity of the pyramids. The first mention of the Sphinx in any classical text is by the Roman author Pliny, in the first century AD, by which time the entire Sphinx had been excavated and was free of sand. And in that first surviving mention from classical literature, Pliny prominently insists that a king was buried "in the Sphinx." From that time, the beliefs that there was a chamber beneath the Sphinx and that a royal personage was buried there in such a chamber have grown into perennial obsessions.

But this has now, in our own time, turned into something more than just curiosity. Millions of people around the world today have become fixated on the Sphinx as an object that is at the center of conspiratorial acts of concealment, both ancient and modern. The interest is not really so much in the Sphinx itself. The question on people's minds is: Is there a chamber beneath the Sphinx? Or, better still, is there a *secret* chamber?

Many books have now been devoted to this subject, which apparently have their origins in the clairvoyant perceptions of an American psychic named Edgar Cayce several decades ago. But despite all the talk, there has so far been a lack of ultimate or conclusive evidence that there is a chamber under the Sphinx, secret or not. Some soundings by high-technology gear have, as we shall see, suggested that there were cavities—many people prefer to call them chambers—in the rock beneath the Sphinx. The situation is complicated by the fact that the Giza Plateau is made of limestone and contains countless natural subterranean cavities in the rock.

Figure 1.1. A view of the Sphinx that is never seen. I believe it has never been photographed from this precise angle. The Great Pyramid is in the background, and the white object at the base of its south face is the museum containing the ancient boat that was found buried in a pit at the foot of the pyramid. I took this photo leaning dangerously far over the southwestern corner of the roof of the Valley Temple, where no one is allowed to go today. (I had special permission from the Egyptian Supreme Council of Antiquities to do some work there.) On the other side of the fence in the foreground is the beginning of the Chephren Causeway, which extends up the hill to the Pyramid of Chephren, which is to the far left of the photo. (*Photo by Robert Temple*)

In one "shallow seismic refraction" study, published in *The First International Symposium on the Great Sphinx*, *Book of Proceedings* in 1992, the conclusions about the "underground structure" surrounding the Sphinx are amazingly bland and essentially amount to this: "The underground Structure below the Sphinx area is composed of different layers of Limestone. . . . From all seismograms recorded, there is no indication of faulting." <sup>1</sup>

Figure 1.2. This amusing view of the Sphinx's head sticking out of the sand was published by Dominique-Vivant Denon in his book of travels in Egypt published in 1810. It represents the Sphinx as it was in 1798 and 1799, at the time of the arrival of the Napoleonic expedition to Egypt, with which Denon traveled. The men seem to be measuring the height of the head above the ground. (Collection of Robert Temple)

Figure 1.3. The head of the Sphinx circa 1910, almost submerged again. (Collection of Robert Temple)

Figure 1.4. This evocative lithograph of the Sphinx dates from 1839 and was drawn by David Roberts, famous for his many artistic views of Egypt at that time. This view shows how the sand has once more engulfed the Sphinx after the excavations of Caviglia. (Collection of Robert Temple)

Figure 1.5. An old glass slide of unknown date, showing the Sphinx covered up to the shoulders in a sea of sand. Note the ragged edge of the left lappet of the Sphinx's headdress, which today is smoothed out with modern cement. (*Collection of Robert Temple*)

Figure 1.6. This photo is dated 1869. All we have is a sea of sand around the Sphinx, and of course the inevitable locals with nothing much to do that day. (*Collection of Robert Temple*)

Figure 1.7. This old photo is also dated 1869. We can see how both the Valley Temple and the Sphinx Temple were at this time so entirely buried under vast sand dunes (in the foreground) that there was no hint of their existence. (*Collection of Robert Temple*)

This is not very exciting.

In an earlier book, *Applications of Modern Sensing Techniques to Egyptology* (1977), we learn that the use of a magnetometer at the Sphinx, which was briefly used "in about an hour of working time," didn't find anything of interest. The authors conclude: "If anything interesting beneath the Sphinx exists, it is likely to be a shaft or cavity, probably now filled, which would have a very small magnetic anomaly. In fact, cavities or voids cannot normally be detected by a magnetometer if the cavity is much deeper than its own diameter."<sup>2</sup>

This is also pretty disappointing. However, a resistivity study (a study of the resistance to the flow of electricity through a material, and how this varies from place to place) at the Sphinx came up with some much more exciting findings, which the report describes as follows:

Several anomalies were observed as a result of our resistivity survey at the Sphinx. . . . A very limited number of measurements were taken due to the time scheduling of the project. As a result of the survey, the team discovered five areas of interest.

Behind the rear paws (northwest end) we ran two traverses. . . . Both traverses indicate an anomaly that could possibly be due to a tunnel aligned northwest to southeast.

Another anomaly exists in the middle of the south side near a square cupola added apparently in Roman times. This anomaly was verified by two overlapping traverses. . . . When the electrodes were moved 2m away from the previous traverse, the anomaly decreased in value. This is typical of the behaviour expected from a vertical shaft. . . . There are two anomalies in front of the front paws of the Sphinx. The bedrock in front of the Sphinx is covered with Roman-era paving stones and poor electrical contact between the paving stones and bedrock gave somewhat noisy resistivity traverses. However, one anomaly occurs on large electrode spacings, suggesting a cavity or shaft as much as 10m deep. The cavity, if present, is probably filled with rubble. . . . We feel that a more detailed survey should be conducted.<sup>3</sup>

This report is not widely available, and copies are hard to find. I have been fortunate to obtain one. It is doubtless the lack of clarity and reporting of information on these matters that has encouraged a vast number of members of the reading public to become convinced that there is at present a vast and sinister conspiracy to cover up secret knowledge of underground chambers at the Sphinx.

Figure 1.8. A view of the Sphinx from the roof of the Valley Temple. Just behind the Sphinx's right shoulder are the two strange "boxes," the large one in front and the smaller not far behind it, that protrude from the Sphinx's body and are unexplained, and are certainly later in date than the Sphinx itself. Although the smaller one could easily have been a statue base, the larger one rises so high that any statue of comparable proportions would have acted as a serious distraction to the Sphinx itself, and besides, we have no fragments from excavations of such a gigantic statue. In this photo, the light allows us to see the strikingly different color of the recarved head from that of the main body. (*Photo by Robert Temple*)

But the problem is more a failure of communication, general vagueness, and lack of enthusiasm among the "conspirators." They are probably covering up little more than that they are themselves lacking any conclusive evidence and are unsure what to think.

This lack of conclusive evidence is surprising, so I am delighted to be able to produce some at last. Now, for the first time, I reveal some *real* reports of a Sphinx chamber from early travelers. There are clear eyewitness accounts from as early as 1678 that we will consider later, but my first knowledge of this evidence comes from an old book of a slightly later date, and we will start with that. This first report that I encountered is rather vague, but it set me off on a very long and onerous search through all the early travelers' reports on the Sphinx to find more evidence, in which I was to be more successful than I had dared imagine.

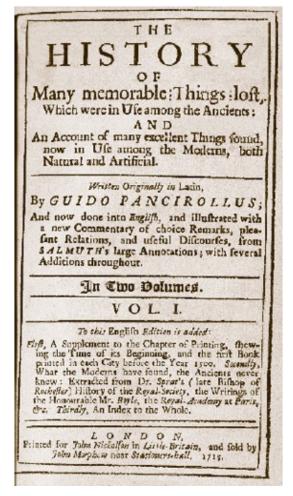

Figure 1.9. The title page of Guido Pancirollo's book *The History of Many Memorable Things Lost*, in its English translation (my own copy), London, 1715.

Let us follow the process of discovery. When I first encountered this information, it appeared to be the only such account of a Sphinx chamber in existence. It was published in 1715, and for nearly three centuries no one had paid the slightest attention to it.

But eventually, everything somehow seems to come to light, and I came across this initial report while researching ancient optical technology for my book *The Crystal Sun*. At that time I looked at the report of the Sphinx only out of mild curiosity. In fact, I photocopied it and did not actually read that section of the photocopy for months, for my attention was elsewhere. The title page of the book, and the page about the Sphinx, are reproduced in figures 1.9 and 1.10.

But before we get into this account published in 1715 and begin to evaluate it, let me tell you about my own experience of entering a chamber beneath the Sphinx. This chamber is known by repute to everyone with a deep interest in the Sphinx; it is the bottom of the little tunnel beneath the Sphinx's rump. You can see the relatively tiny size of the tunnel in figures 1.11 to 1.13, and me crawling out of it in figure 1.14.

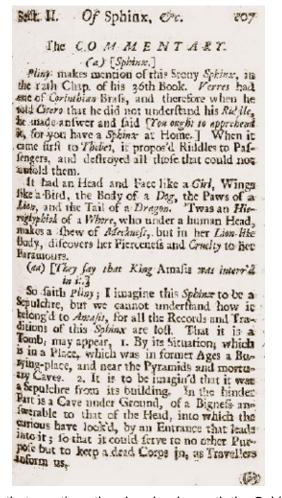

Figure 1.10. The page in Pancirollo's book that mentions the chamber beneath the Sphinx, which was the first pubished account of it I came across, although it was not the earliest, as I was to discover.

The rump tunnel, if that is not too rude a designation, has been entered by only a tiny handful of people. It is not at all easy to photograph the rump tunnel, because it is very narrow and cramped and there are not many features; and to demonstrate the scale, presumably someone should stand in the photo at the bottom of the tunnel, after first removing the accumulated rubbish. I have been unable to get the necessary lights or organize such a photo, and I am unaware of anyone else ever having done so. But some impression of the interior of the tunnel may be obtained from my flash photo in figure 1.15.

Figure 1.11. This tiny hole at the base of the rear end of the Sphinx of Giza shows the entrance to a passage that descends 20 feet. (Photo by Robert Temple)

Figure 1.12. A close-up photo of the entrance to the rump tunnel. All the flat limestone blocks are modern reconstruction stones, not part of the original Sphinx. The way the bedrock has been cut away in a circular shape may here be seen clearly. The top of an interior modern steel support may also be seen. Behind the reconstruction blocks, a bit of the original Sphinx stone may be glimpsed above the hole. The rough workmanship and clumsy hacking evident here demonstrate that this is an intruded shaft from a late period that never formed part of the original intention of the Sphinx. It takes a thin person to squeeze inside. (*Photo by Robert Temple*)

Figure 1.13. It's amazing how much there is to see when you look down below the Sphinx's bottom. (Photo by Olivia Temple)

Figure 1.14. Here I am emerging from the "rump tunnel" beneath the Sphinx or, to put it more bluntly, with my head sticking out of the Sphinx's ass. The original stone can be seen behind me underneath the layer of smooth modern restoration blocks. (Photo by Olivia Temple)

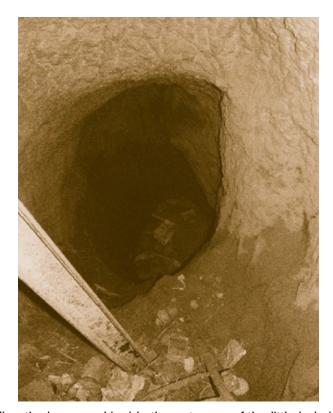

Figure 1.15. This is a photo looking directly downward inside the entrance of the little hole in the Sphinx's bottom. This shaft and pit have been excavated out of the bedrock. As may be seen, it is all littered with tourist rubbish. But the pieces of paper lying on the bottom help one get an accurate scale. The pit is about 15 feet down, has no sign of water, and would comfortably allow a single person to "incubate" overnight in search of a sacred dream. It is too small for a tomb. Because the shaft is so crudely cut out of the rock, showing no regularity or professionalism, it must be a late intruded shaft. It probably dates from the Ptolemaic Period and was used under the Greeks and Romans, at a high price to selected persons, for healing and inspiration purposes. Since it could be used only 365 times a year, by one person at a time, the number of clients was necessarily small. Alternatively, the hole may have been used for someone to sleep overnight to prepare him or her to deliver oracular prophecies through a speaking tube at dawn, when the crowds came to pray to the Sphinx. This shaft continues upward and curves around the southern side of the Sphinx. (*Photo by Robert Temple*)

Squeezing into the tiny opening at the base of the Sphinx's rump is a difficult business (see figure 1.13). As soon as you stick your head in, you can see that a metal ladder has been affixed inside, onto which you can cling, so that you can hoist yourself around and have something to hold on to. Then you can clamber into an upright position. Once you are standing, and not perilously poised over a hole, you can take the time to look around you. Naturally, you have to have a light in your hand or you cannot see a thing.

What you can see from the ladder is that a narrow tunnel about 15 feet deep has been dug out of the rock. At the bottom, the first thing you notice is a lot of rubbish that has blown in through the hole, as the

Giza Plateau is covered with masses of rubbish dropped every day by tourists and visitors. As you peer intently to see just what is at the bottom, it becomes clear that the rock has been scooped to form a rounded hollow that is big enough for two people to stand in side by side.

What struck me about this hollow was that a lot of trouble seemed to have been taken to create it, and it did not resemble the effort of a treasure seeker. I had the impression that its real purpose was to enable a person to curl up in a bed and lie there comfortably overnight, or at least for some hours. My reaction to seeing this "cell," for that is what it reminded me of, was to assume that this is where special acts of incubation may have taken place. *Incubation* is the word used to describe the ancient practice, common among the Greeks, of sleeping in a temple overnight in order to have a sacred dream. The Greeks generally did this for medical reasons, in temples of their god of medicine, Asclepius. A typical example of such a temple is at Epidauros in the Pelopponese in Greece.

In Greek incubation, a sacred dream would come to the lucky person sleeping in the holy spot, and this dream would reveal the means of cure of the ailment. Other forms of incubation might have different aims: inspiration, prophecy, divine guidance, or communion with the divine might be sought instead of cures for disease. A classic book on this subject was written by Mary Hamilton, who says about Isis and "incubation":

If the [account of Diodorus Siculus saying that the goddess Isis healed people in their sleep] were to be taken literally, it would mean that the activity of Isis as an iatromantic [medically prophesying] oracle reached far back into the obscurer centuries, and that incubation had been an Egyptian practice from early times. The importance of the role of Isis in medical science cannot be denied, but Welcker refuses to credit her with the position assigned by Diodorus. He considers that the priesthood established such a tradition at a late date in order to strengthen faith in the new practices of their health-oracles by fortifying them with the assurance of antiquity. He believes that only under the Ptolemies [commencing in the late fourth century BC] did Isis begin to rank as a goddess of healing. . . . It may be that then, for the first time, the practice of incubation became general in Egypt, but as a healing goddess Isis had been honoured many centuries before. 4

I am inclined to believe that the Sphinx rump tunnel, whatever its original date may be, was known and used during the period when we know that the Sphinx was cleared of sand under the Ptolemies, the period of Greek rule and Greek religious influence subsequent to the fourth century BC. Only the most special visitors, who were prepared to pay the priests a lot of money for the privilege, would have been allowed to sleep overnight beneath the rear of the Sphinx. After all, unlike the temples of Asclepius that could accommodate sometimes dozens of visitors at a time in incubation cells, the hollow beneath the Sphinx could hold only one person at a time. The Sphinx inspired a great deal of awe and at this late period was considered a sacred idol, who was called Harmachis; sacrifices were offered to it as a god, in front of the statue, where an altar existed between its paws (see figures 1.16 to 1.22). To be allowed to sleep beneath the Sphinx would have been a powerful and overwhelming experience, and by the power of autosuggestion alone, aside from any other factors, many clients would have been bound to have apocalyptic dreams. The word-of-mouth reputation would have created a vast waiting list of people wishing to have these experiences, just as there are thousands of tourists today who are prepared to pay extra fees to their tour groups for the privilege of standing between the paws of the Sphinx. People will always swarm to any place of healing, as Lourdes proves in our own day.

The vast stairway leading down to the Sphinx in Ptolemaic and Roman times is shown in figures 6.44 and 6.45, figure 6.45 being drawn shortly after its excavation in 1817. Not a stone of this stairway now

remains, as it concealed a temple beneath, which has now been excavated (the Sphinx Temple). Indeed, this early drawing is apparently the only picture in existence of what the approach to the Sphinx looked like at that period of history. It was clearly designed for the use of large crowds, with smoking altars placed at intervals of the stairway as part of the crowd-management techniques in connection with the public ceremonies and mass access for offerings and worship. Countless offerings left both by the ordinary public and by dignitaries were dug up from around the Sphinx during the various excavations that took place between 1817 and 1937.

Figure 1.16. This old photo from 1896/1897 contains a contemporary inscription that gives us information that I have found nowhere else, namely that Colonel George Raum carried out excavations at the Sphinx in 1896. I don't believe there is any other surviving evidence that these excavations took place. Nor have I ever heard before of the "stone cap." The inscription reads: "Some successfull [sic] excavations at the foot of the Sphinx have recently been carried out by Col. Raum. In 1896 the stone cap was discovered—This discovery seems to have been of much advance by Dean Stanley who in his Travels wonders apropos of the colossal head of the Sphinx 'What a sight it must have been when on its head was the Royal Helmet of Egypt." (Note: The American colonel George Edward Raum, of San Francisco, arrived in Egypt in 1885. He found a portion of the "rock crown" of the Sphinx in an excavation between its forepaws on 26 February 1896.) (Collection of Robert Temple)

Figure 1.17. This mid- to late-nineteenth-century photo by a French photographer based at Port Said shows the north side of the Sphinx Moat (on the right in this photo) not only totally unexcavated but still containing late overlying structures protruding from the sand. Here, just above the left paw of the Sphinx, we can see the remains of a stone wall, for instance. At this period, the north side of the Sphinx Moat had not been clear since the time of the Roman Empire—in other words, for about 1,800 or 1,900 years. The small stones covering the toes of the Sphinx are reconstruction blocks dating from Roman times. (*Collection of Robert Temple*)

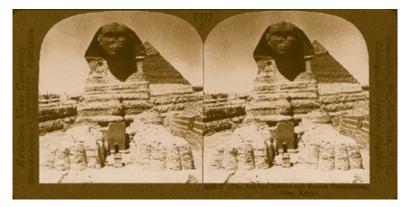

Figure 1.18. This stereoview was taken between 1926 and 1936, since it shows at far right the walls erected by Baraize in 1926 to hold back the sand on the north. The walls were demolished by Selim Hassan in 1936. (Collection of Robert Temple)

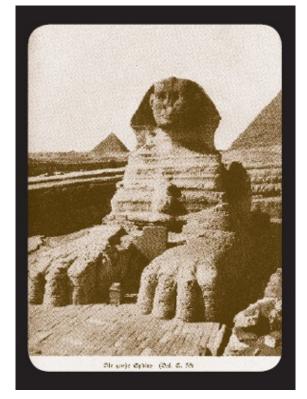

Figure 1.19. This photo shows very clearly the small altar between the paws of the Sphinx, at which offerings were burned during Roman times, when the Sphinx was thought to be a god named Harmachis. Farther back, between the paws and up against the chest of the Sphinx, stands the Dream Stela. This photo comes from Adolf Erman's book *Die Welt am Nil (The World on the Nile)*, Leipzig, 1936, where it is Plate 13 opposite page 58. Erman credits Ludwig Borchardt. This photo probably dates from 1936, immediately after the lappets of the headdress had been "restored" by Selim Hassan, as the new concrete lower portions are still so fresh that they are far paler than the stone. Subsequently, the concrete darkened during curing, and this contrast was no longer so obvious.

Figure 1.20. This photo, probably dating from about 1850/1860, shows the limits of Caviglia's excavation of 1817. The little wall above the left foreleg of the Sphinx suggests that Caviglia never cleared the sand much farther than a few feet to the north of that foreleg. As for the south side of the Sphinx (its right, left of photo), the sand was right up to shoulder height. Nevertheless, we can see in the background that the rump is entirely clear. An Arab squats at the base of the Sphinx's neck on the north side.

(Collection of Robert Temple)

Figure 1.21. I am inclined to suspect this glass slide is very early indeed. It shows the results of Caviglia having tried to make some clearance to the south, and just a bit at the north, of the Sphinx. The photo may be circa 1830, but I am just guessing. (Collection of Robert Temple)

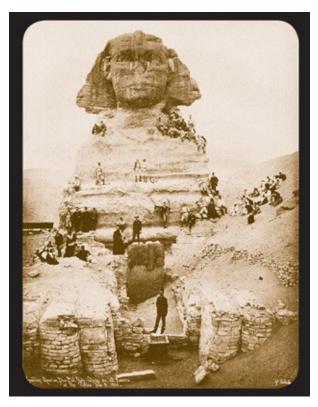

Figure 1.22. This very strange photo shows the Sphinx acting as host to a visiting American baseball team! The photo was taken in 1889, and the baseball players were traveling with Albert Spalding; they were known as the Spalding National League. They went on a world tour "to bring baseball, and with it the American way, to the four corners of the earth," as it says in a book by Mark Lamster, *Spalding's World Tour*, New York, 2006. This photo gives a good view of the true condition of the paws of the Sphinx, as they were when still constituted of small stones dating from Roman times; today, these are completely covered in modern stones, and none of the Roman ones can be seen any longer beneath the present covering of white limestone blocks. (*Collection of Robert Temple*)

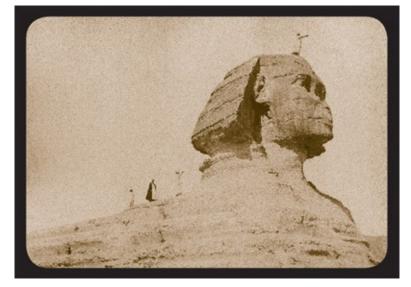

Figure 1.23. A photo circa 1870 showing a man standing on top of the Sphinx's forehead, his arm extended toward the east. Three figures stand on the back, just behind the head. This photo enables us to appreciate the scale of the sculpture, and even though the head is far too small for the body, it still utterly dwarfs the man. (Collection of Robert Temple)

Another interesting point is the connection of Isis with incubation, at least by Ptolemaic times. As may be seen in part 2, section 2, where I have gathered travelers' accounts of the Sphinx from Pliny up to the mid-nineteenth century, the tales of the Sphinx dating from the Middle Ages sometimes referred to the statue as "the Idol of Isis." This appears to be a survival of an old tradition that may refer to the association of incubation at the Sphinx with the patron goddess of such things, Isis. There was even a small Temple of Isis nearby during this period, just a short distance northwest of the Sphinx (see figures 1.24 to 1.27). This temple is mentioned by name in an enigmatic stela excavated at Giza that has come to be called the Inventory Stela (figures 5.12 and 5.13). The Inventory Stela is discussed in chapter 5.

The actual passage in Diodorus Siculus (circa 80–20 BC) is interesting to read. First I give it in the charming translation by Booth that was published in 1700, from one of my old leather-bound translation volumes: "The Egyptians report that Isis found out many medicines for the recovery of men's health, being very expert in the art of physick, and contriv'd many remedies for that purpose; and therefore even now when she is advanc'd to an immortal state, she takes pleasure in curing men's bodies, and to those that desire her assistance, in their sleep she clearly manifests her presence, and affords ready and effectual relief to them that stand in need of it." <sup>5</sup>

The modern translation, of which I give a greater portion, is less quaint:

As for Isis, the Egyptians say that she was the discoverer of many health-giving drugs and was greatly versed in the science of healing; consequently, now that she has attained immortality, she finds her greatest delight in the healing of mankind and gives aid in their sleep to those who call upon her, plainly manifesting both her very presence and her beneficence towards men who ask her help. In proof of this, as they say, they advance not legends, as the Greeks do, but manifest facts, for practically the entire inhabited world is their witness, in that it eagerly contributes to the honours of Isis, because she manifests herself in healings. For standing above the sick in their sleep she gives them aid for their diseases and works remarkable cures upon such as submit themselves to her; and many who have been despaired of by their physicians because of the difficult nature of their malady are restored to health by her, while numbers who have altogether lost the use of their eyes or of some other part of their body, whenever they turn for help to this goddess, are restored to their previous condition. Furthermore, she discovered also the drug which gives immortality.<sup>6</sup>

This explicit testimony from a writer of the first century BC makes it very clear that incubation at an Isis center was taking place in Egypt during Greek and Roman times. We can safely presume that this was happening at the Temple of Isis on the island of Philae, in the south of Egypt. However, the only Isis temple I know of in the north of Egypt is the one at Giza. It was so small that it is difficult to imagine incubation taking place there. I believe the evidence warrants the assumption that the cell beneath the rump of the Sphinx was used for incubation, and that the priests of the small Temple of Isis nearby were the ones who arranged this. As for Diodorus's reference to Isis becoming known all over the world for her healing abilities, this refers to the fact that during the Greek and Roman periods, Isis temples were founded all over the Mediterranean. Anyone who has visited Pompeii will have seen the one there, which is so well preserved. There was one in every Roman town of size. The Isis temple in Paris was outside the city walls of the Roman town (known as Lutetia) and was on the site of the modern Church of Saint-Sulpice.

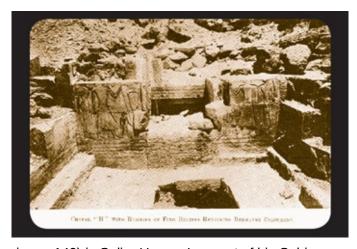

Figure 1.24. This is plate LIV (following p. 140) in Selim Hassan's report of his Sphinx excavations, *The Great Sphinx and Its Secrets: Historical Studies in the Light of Recent Excavations*, volume VIII of the series *Excavations at Giza*, in this case for the years 1936–37, Government Press, Cairo, 1953. This photo shows the chapel of the Temple of Isis at Giza that led into the inner sanctum. On Hassan's plan of the temple (see figure 1.25 below) this chapel is marked "H." This photo appears to have been taken facing north, from the inner sanctum itself looking outward through the chapel doorway. According to Hassan (p. 111), this temple was probably constructed during the Eighteenth Dynasty of the New Kingdom, as we know that King Ay, the successor of Tutankhamun, made an offering there, as did other New Kingdom personalities. After the reign of Rameses II, the temple seems to have experienced a decline, until it was revived in the Saite Period (664–525 BC), when it was once again very important up until the time of the Persian Conquest in 525 BC.

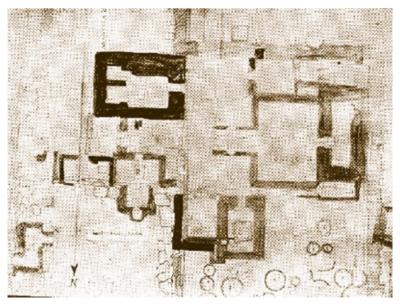

Figure 1.25. This is plate LII from Selim Hassan's book, *The Great Sphinx and Its Secrets*, Cairo, 1953. It shows Hassan's drawing of the plan of the ruined Temple of Isis, which lies at the foot of the Great Pyramid on the eastern side.

Figure 1.26. This photo is plate XLVIII in Selim Hassan's book, *The Great Sphinx and Its Secrets*, Cairo, 1953. It is of a limestone stela excavated in the Sphinx Pit showing the pharaoh Thutmosis (Thothmes) IV offering flowers to the goddess Isis, who holds a *uas* scepter in one hand and an ankh in the other. As we have already seen, a late Temple of Isis existed at Giza, though we do not know how far back her association with Giza extended. Clearly, in the New Kingdom, it was thought suitable to honor her in the Sphinx Pit, which was no longer a moat; it was completely dry.

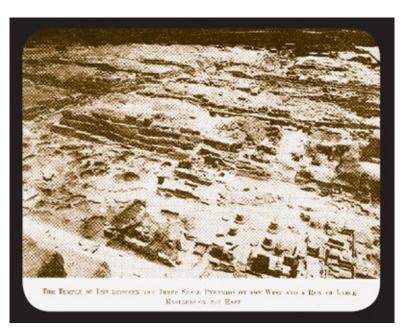

Figure 1.27. A photo taken from the Great Pyramid, looking down on the remains of the Temple of Isis just to the east of the pyramid (the round column bases are part of it). This temple does not date from the time of the pyramids, but was a later edifice, built partially on top of one of the tombs dating from the reign of King Cheops. No one knows whether an earlier Temple of Isis existed at Giza, as claimed by the Inventory Stela, which may or may not draw on Old Kingdom texts. During the Middle Ages, the Sphinx was generally thought to be an image of the goddess Isis, because the *nemes* headdress worn by the pharaoh looked like a woman's bonnet, and people generally could not accept that it was the head of a man. This photo is plate LI in Selim Hassan's book, *The Great Sphinx and Its Secrets*, Cairo, 1953.

An alternative and possibly double use for the rump tunnel occurred to me when I was exploring it: during the worship of the Sphinx, it might have been consulted for oracular revelations. A priest might have lain concealed in the hollow beneath the Sphinx, which he would have entered under cover of darkness and where he would have remained until the following night, and during the daytime he could have spoken through a speaking tube to reply to inquirers' questions. People would have thought the Sphinx itself was speaking. Such tricks were played frequently in Ptolemaic times in Egypt, and trick chambers and passageways, holes for speaking tubes and so forth, can be seen in many surviving ruins of temples such as Kom Ombo and Edfu. The rump hollow is a cozy enough little cell to curl up in for a day

or so, with your water jug and some food beside you, and a chamber pot nearby. Also, as we shall now see, there was a connecting tunnel to help enable such voice tricks to be relayed toward the front of the Sphinx. At the time I thought of this, I had not yet done my searches of the early travelers' reports of the Sphinx and was unaware that many of them had repeated the claims of the local population that someone concealed himself within the Sphinx in ancient times to deliver oracles. The fact that I thought of this idea independently and only later found it confirmed by countless early reports strengthens my conviction that there must be some truth in it. There is no hole in the mouth of the Sphinx by which oracles could be delivered, but as we will see later when we go into much more detail, there was another and better means of doing so.

So the rump hollow was probably either an incubation cell or an oracular hole, or perhaps it served as both. But there is more to it than just that. One's first suspicion is to think that perhaps the tunnel goes down farther, but this does not appear to be possible. I looked pretty carefully at the hollow, and the scooping away of the stone in a rounded fashion is clearly out of the bedrock. This tunnel does not go any farther down, nor was it ever intended to. There was no trace of water. The hole appeared perfectly dry, which is strange considering that water—supposedly from the rising water table—has been reported at higher levels elsewhere in association with the base of the Sphinx. The whole question of where water is and where it is not within the underground region of Giza is a complicated one, perhaps made more so by the fact that the limestone of the plateau is riddled with cavities like a Swiss cheese.

But what is very surprising indeed is that the Sphinx rump tunnel *does* continue—upward. After I had finished peering down, my attention was finally drawn to what was above my head. And then I had a great shock, for the tunnel beneath the Sphinx *continues upward into the body of the Sphinx*.

I was certainly not expecting this. The upward tunnel is not straight, and it is rough-hewn. It curves around out of sight, and I was not able to see the end of it. All along the upward tunnel, wooden supports have been erected, as in a mine shaft, presumably to prevent the collapse of the rear of the Sphinx upon itself (see figure 1.28). These wooden props appeared to be very new, placed there at the time of the restoration of the Sphinx in the mid- to late 1990s, during the period when the Sphinx was covered with scaffolding. Although the upward tunnel was largely blocked by these struts, I was tempted nevertheless to crawl along at least sufficiently to have a look around the bend to see an end to the tunnel. But I decided against this idea when the very first wooden support by the ladder, against which I leaned slightly, moved! The possibility of dying inside the Sphinx, crushed by its collapsing rump, did not appeal to me, if only because I could not then make my report. So I was unable to form a personal impression of just how far this extraordinary interior tunnel in the Sphinx actually extended. It went both upward and along, curving up the rear haunch slightly toward the south and then heading around toward the east and disappearing out of sight in the direction of the Sphinx's waist.

Figure 1.28. This is a photo looking upward inside the rump of the Sphinx. It shows the commencement of the tunnel that curves up inside the Sphinx from the top of the Sphinx's right hip until it comes to the point where Baraize filled it with cement in 1926. Before he did that, it certainly went at least as far as the crevice where the haunches had been broken off from the main body for centuries, until Baraize joined them again. That was the point where the shaft and burial chamber had been intruded into the Sphinx. The shaft and this tunnel would therefore once have intersected. Whether this tunnel ever continued beyond the shaft, farther forward to the front of the Sphinx's body, is entirely unknown to us now. Several wooden props have been placed here to support the Sphinx from inside, making it impossible for anyone to squeeze past them and crawl along this tunnel. (*Photo by Robert Temple*)

It is immediately obvious that this interior tunnel provided a very convenient means in antiquity of conveying a crawling person who had slept overnight in the hollow, or alternatively of conveying his voice along a speaking tube to a forward part of the Sphinx, whether the area of the hips or beyond, so that oracular pronouncements could have been made and superstitious people would genuinely believe that the Sphinx had spoken to them with its voice. The actual location from which utterances might have emerged is something I will discuss later, but it was certainly not on the Sphinx's face or head. (There is a hole in the top of the head, but it was drilled for another purpose and does not connect with any other holes.)

Because I am a friend of the limestone expert Professor Lal Gauri, who worked for some years in the late 1970s with Zahi Hawass and Mark Lehner on the stone of the Sphinx, I sent him an e-mail asking him about this strange interior tunnel in the Sphinx. I knew that he too had been down the rump tunnel. He replied that he had also noticed the tunnel continuing upward and bending around out of sight, but he had not crawled along it or explored it either. He knew no more about it than I did.

If an expert who worked on the Sphinx for years does not know how far the tunnel goes, then the number of people who do must be very small indeed.

Perplexed, I talked to someone else about the matter. He had some familiarity with the tunnel. He told me the Sphinx tunnel "goes 6 meters down and 8 meters upwards." By that he meant that the hollow was 20 feet beneath the Sphinx base, and that the upward tunnel had a length of 26 feet, meaning that it went about twice as far as I could see. What happened then he didn't say clearly, except that it apparently came to an end of some kind. But unlike the hollow, which seems to stop at bedrock, one could presumably never be sure if something like an interior tunnel really ended naturally or had been blocked by a later

repair. The hip area of the Sphinx has experienced a great deal of weakness and been repaired at various times throughout history. The question we have to keep firmly in mind is this: Why would anyone drive such a long tunnel along the length of the Sphinx if there was no purpose, or no objective at the end of it? It had to lead to *something*.

It was not until January 2001 that a colleague kindly gave me a photocopy of an article about the Sphinx Tunnel that had been published by Zahi Hawass and Mark Lehner in 1994 in a French Festschrift for the Egyptologist Jean Leclant. This article gives a very full account of the rump tunnel. But previous to seeing this article, I had been puzzled at the lack of information available about it. Hawass published a booklet about the Sphinx four years later in which he gave relatively few details, and there was no indication in this later work that there was an earlier and fuller publication on the subject. In this brief booklet, *The Secrets of the Sphinx*, published in 1998, Hawass writes only this:

#### Tunnels under the Sphinx

Over the years, the Sphinx has revealed some of its secrets, though not all. In 1881 [sic; Vyse actually worked at the Sphinx in the 1830s] Henry Vyse found two tunnels inside the Sphinx, but his discovery was never published. In 1979, we opened these tunnels. [It was at this time that my friend Lal Gauri was working with Hawass on the Sphinx and went down the rump tunnel.]

The first tunnel is located behind the head of the Sphinx, cut into the mother rock about six meters. The second tunnel is located in the tail of the Sphinx. We learned of it from Sheikh Mohamed Abd al-Maugus, who in turn knew of it from his grandfather. It too is cut into the mother rock, about twelve meters. We found no significant artifacts inside the tunnel, but the evidence suggests that the tunnels were cut during the pharaonic period, I believe during the Twenty-sixth Dynasty [664–525 BC].

A third tunnel in the north side of the Sphinx, has not been opened since 1926, when Emile Baraize opened it. We have photographs showing two workmen inside it.<sup>8</sup> [These are the archive photos taken by Pierre Lacau in 1926, which I was not permitted to see, as I describe later.]

This was all he said, and it left me wondering: Why has no one explored the tunnel, which has been unopened since 1926? In figure 1.37 Olivia stands in front of this blocked doorway. It is so obvious that someone should remove some of those modern stones and have a look at what is behind them. Why has no one done that?

Another question I have is this: What evidence suggests that the rump tunnel dates from the Twenty-sixth Dynasty? If no "significant" artifacts were found inside the tunnel, what were the *insignificant* ones? In fact, I know what one was: Hawass told me he found an old pair of shoes at the bottom of the rump tunnel. But he did not say shoes of which period. Were they modern? Ptolemaic? Turkish? (They were evidently modern but not recent, as I later discovered.)

The 1994 article published in the French Festchrift is relatively little known. Leclant is a famous figure in Egyptology, and I met him in 2000. Presumably because he and Hawass have been friends since 1976, his Festschrift was chosen as the vehicle for this publication, but awareness of the article outside of professional Egyptological circles has been nil. For instance, it was obviously unknown to Paul Jordan, who wrote a book in 1998 that was entirely devoted to the Sphinx.<sup>9</sup>

When Jordan's book was published, I was overjoyed and rushed to order it. At last I would get some answers to the Sphinx tunnels, I hoped. But no, not at all. Sphinx tunnels are mentioned only twice, and we are told very little. On page 5, the author says, presumably drawing upon Hawass:

There are three passages into or under the Sphinx, two of them of obscure origin. The one of known cause is a short dead-end shaft behind the head drilled in the nineteenth century. No other tunnels or chambers in or under the Sphinx are known to exist. [This is demonstrably untrue; anyone can see the small chamber underground between the paws, for instance. A photo of the entrance to it may be seen in figure 1.29. And we shall see as we go along that the tunnels and chambers are more than we imagined.] A number of small holes in the Sphinx body may relate to scaffolding at the time of carving.

And on page 25, the same author adds:

Helferich [a sixteenth-century traveler, more correctly known as Johann Helffrich, or in Latin, Johannes Helfricus, who mentioned the Sphinx in his book of travels written in German in 1579, <sup>10</sup> to which Jordan gives no reference or title, however] adds a teasing detail that echoes down to our own day when he tells that "from afar, under the ground, through a narrow hidden passage, one can pass unseen. By this passage the heathen priests get inside the head and speak to the people out of it as if the statue itself had spoken."

Figure 1.29. I lifted the lid and took this photo of the modern metal frame that has been inserted into the bedrock floor of the Sphinx Pit between the feet of the Sphinx. This is the entrance to the underground chamber in front of the Sphinx. Not only is the metal covering a modern one, but the chamber inside now contains modern bricks, put there by Henry Salt. A tunnel originally led off from this hole underground, but it was blocked in 1817 or 1818 by Henry Salt, according to an account left by Count Forbin, so we do not know where it led. This small chamber in the rock is probably where someone giving oracles sat and spoke through a tube to convince people that the Sphinx itself was speaking to them. I suggest that this happened not originally, but rather after the Sphinx was cleared of sand by King Thutmosis IV during the New Kingdom, and then again after the Sphinx was later cleared repeatedly during the Twenty-sixth Dynasty, the Ptolemaic Period, and the Roman period. During these later periods, the Sphinx was worshipped as an idol in a superstitious fashion. (*Photo by Robert Temple*)

That is all. But in our consideration of early descriptions of the Sphinx, as we shall see, there were many such accounts given by early travelers of secret passages and tunnels. Indeed, there are so many such accounts in my compilation of the earliest reports, which extends from Pliny until 1798, that they are rather overwhelming. (Later reports are in part 2, section 2, which presents early-nineteenthcentury travelers' accounts.)

Although the 1994 article by Hawass and Lehner has received little or no attention, it is the definitive account of the rump tunnel, and we must see what it has to tell us. The story of the discovery of the rump tunnel in modern times is absolutely fascinating, not least because the existence of this tunnel was

revealed by a man named Mohammed Fayed (not the father of Dodi Fayed, the late Princess Diana's boyfriend). I quote the beginning of the Hawass and Lehner article:

It is an age-old notion that the Sphinx conceals some sort of passage, tunnel, grotto, or chamber. The idea enjoys wide currency today in popular nonscientific publications about the Giza monuments.

During our work at the Sphinx, three elderly men in the employ of the Antiquities Organization at Giza told us of a passage under the rump of the Sphinx. They said that they saw the passage when Baraize revealed it in 1926 during his cleaning of the Sphinx, for which they worked as basket carriers. They said that the passage opened at floor level on the north side of the rump as it curves from the beginning of the tail. One of these men, Mohammed Abd al-Mawgud Fayed, recalled, some fifty-seven years after Baraize's excavation, that the opening of the passage was a round hole just under the masonry veneer. The passage descended to the water table under the Sphinx.

Like so much of Baraize's work, the passage went entirely undocumented and, since it was covered with masonry, it was nearly forgotten. Since the water table is a critical factor in the preservation of the Sphinx, and because such a passage would be an important part of the history of the statue, we decided to investigate these claims. Baraize covered the opening of the passage with stones and cement. It had been almost six decades since Mohammed Abd al-Mawgud had last seen the opening. Nevertheless, Mohammed was able to point to a specific brick-sized stone, bonded with modern cement, that could be removed to reveal the opening.

On October 16, 1980, we moved this single small slab to expose a grey cement packing characteristic of Baraize's repairs on the Sphinx. We forced a small hole through this packing and found that the bedrock floor dropped off into a cavity under the brick-sized veneer masonry that Baraize had replaced. Behind the brick-sized and cement/limestone packing Baraize had set a large limestone slab to bridge the opening of the passage. We moved the bridging slab to allow easier access. Behind it were two larger slabs set end to end to bridge the opening. 11

It is good to have this candid tale on record, revealing how an attentive ear to the tales of the workmen can often result in the most significant discoveries in archaeology. We should also note that although the rump tunnel was discovered in 1980, it took fourteen years for an account of it to be published by its discoverers. Such are the delays of archaeological publication. That also explains why Lal Gauri was unaware of it, as no one bothered to send him a copy fourteen years later, and he does not read French Egyptological Festschrift volumes as a hobby, not being an Egyptologist.

The Hawass and Lehner article reveals the official measurements of the rump tunnel:

The passage consists of an upper and lower part. . . . The lower part descends from a circular hole in the floor where it meets the rise of the bedrock core body. It slopes downward at a very steep angle towards the northeast, for a distance of 4 m. and a depth of 5 m. and terminates in a cul-de-sac in the natural rock. Just inside the entrance, the passage is 1.30 m. wide and narrows to 1.07 m. near the bottom. . . . The upper part of the passage rises to a height of 4 m. above the Sphinx floor and ends in a niche about 1 m. wide and 1.80 m. in height. It is about 1 m. wide at the lower end and measures 1.80 m. in width just before the niche. 12

Hawass and Lehner give no measurement of the length of the upper part of the passage in their report, or of how far it actually extends into the body of the Sphinx. They mention only how high it goes (13 feet).

Today, with the upper passage filled with wooden struts, it would be nearly impossible to make measurements of it or even to explore it. All the struts would first have to be removed, and whether that would be safe I cannot say, as their existence has not even been admitted by archaeologists, so we cannot draw any conclusions about their necessity.

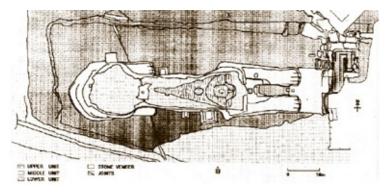

Figure 1.30. This is Professor Lal Gauri's plan of the Sphinx as seen from above. The huge blob of cement that Émile Baraize stuffed into the shaft at the haunches of the Sphinx may be seen here. And running across that blob diagonally, northwest to southeast, is the major fissure in the bedrock beneath the Sphinx that he found. This fissure goes directly across the point at which the subterranean burial chamber lies and was possibly caused by the shocks to the bedrock due to construction when that shaft and chamber were intruded, as they are most unlikely to have been original features of the Sphinx. The surviving description of the burial chamber as having walls covered in hieroglyphics would appear certainly to rule out any date prior to the Fifth Dynasty (hence excluding both Pharaohs Cheops and Chephren) and probably indicate an intruded shaft and chamber dating from Saite times (664–525 BC, ending with the Persian conquest of Egypt), which could even make Pliny's assertion that King Amasis was buried beneath the Sphinx absolutely correct. This drawing is reproduced from K. Lal Gauri, "Weathering and Preservation of the Sphinx Limestone," in *The First International Symposium on the Great Sphinx, Book of Proceedings*, Cairo, 1992, p. 54.

As the reader may have gathered, the "restorations" by the French archaeologist Baraize were pretty drastic and heedless. Figure 1.31 is a particularly rare photo I found of the Sphinx taken circa 1920, before Baraize did the "restorations." This photo was used as the frontispiece to a book published in German by a Polish scientist, Klaus Kleppisch, in 1921, of which I believe no copy exists in Britain except for my own private copy, which I acquired from Switzerland through a German bookseller. Certainly no copy is to be found in the British Library. The photo is taken from an unusual angle, on what we now know as the Chephren Causeway, and it is very revealing.

In the photo we can see that a huge fissure at that time existed in the region of the hips of the Sphinx, and that the entire rump of the Sphinx was effectively detached from the rest of the body. This is not just a minor detail! Because this now vanished feature is so important, I have spent some years collecting other photos that show it; see figures 1.32 to 1.34. These photos are taken from varying angles and help us evaluate the precise nature of the fissure as it existed prior to 1926.

Figure 1.31. This photo, published in 1921, just a few years before Baraize filled it full of cement, shows clearly the cleft separating the main portion of the Sphinx from its rump. The rump had by this time split away due to the structural weakness in the stone caused by the hollow shaft that led down through the entire body of the Sphinx to the burial chamber beneath it at that point. The shaft was not original, but a later intrusion to enable a pharaoh to be buried in a chamber beneath the Sphinx, possibly a Saite pharaoh of the Twenty-sixth Dynasty, the last native Egyptian dynasty (664–525 BC). The Saites were obsessed by the Giza Plateau, and as part of their restoration efforts they may have partially or wholly cleared the Sphinx of sand, or at least cleared enough to give them ready access to the back so that they could make the shaft. By 1926, Baraize had entirely obliterated this evidence and permanently filled in the shaft with cement, thus making access to the subterranean chamber impossible. The rump tunnel inside the Sphinx also now terminates at this point, where Baraize's cement oozed into the tunnel and blocked it too. How far the lateral tunnel may have extended forward into the Sphinx's body, past the cleft and toward the chest, cannot now be determined. This photo appeared as a frontispiece in a rare volume that is not to be found in either the British Library or the Library of Congress, *Die Cheopspyramide: Ein Denkmal mathematischer Erkenntis (The Cheops Pyramid: A Monument of Mathematical Knowledge*), by the brilliant Austrian engineer Klaus Kleppisch, who lived in Warsaw. (*Verlag von R. Oldenbourg, Munich and Berlin, 1921; collection of Robert Temple*)

Figure 1.32. A photo circa the 1860s, showing at extreme left a particularly good view of the "rump crack" of the Sphinx at the point of the shaft leading to the subterranean tomb chamber. At this period, the Valley Temple (on top of which the woman at right is standing) was still entirely covered in sand. The sand that had covered the back of the Sphinx during the 1830s, as seen in the earlier figure 1.4 has now been cleared away again. The low wall of small stones on which the man is seated has long vanished; it was of some late structure of which we know nothing and which probably had no archaeological importance. When tourists became more frequent in late Victorian times, sheds to cater to their needs were erected where these two people are seen, and they all had to be torn down at the beginning of the twentieth century to enable the Valley Temple to be excavated. (Collection of Robert Temple)

Figure 2.12 is my own photo of this region where the fissure once was, and a careful comparison of my photo with the earlier ones reveals the full extent of the massive infilling and "restoration" undertaken by Baraize. In figure 1.30, a drawing of the Sphinx seen from above, the area of infill can also be seen as a massive blob of restoration. And as we will see later in another early traveler's report, there was definitely once a rectangular entrance into the Sphinx here, measuring 4 feet by 2 feet, which restoration,

either in the nineteenth century or in the 1920s, has completely sealed and obscured. The importance of this particular area is that it is the very area where the upper passage inside the Sphinx now terminates in a wall made with modern cement and placed there by Baraize.

In 1920 possibly, or certainly in the early nineteenth century, if one had been prepared to dig out large quantities of sand, one could have descended through the hip fissure of the Sphinx and presumably gained entry not only to the upper passage but also to any continuation of it carried farther forward in the body of the Sphinx and now sealed and forgotten, as the rump tunnel itself was almost forgotten. And in fact, as we shall learn later on, it was in this region that entry to another very remarkable subterranean chamber was effected, descriptions of which from three successive centuries have turned up in my search of original source materials. But we have to leave the description of that until later, as we must first complete our study of the rump tunnel.

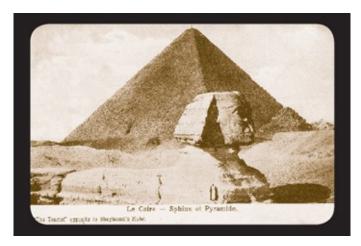

Figure 1.33. This photo, from a postcard that was mailed from Cairo to France in 1909, shows clearly the split-off and detached rump of the Sphinx prior to 1926, just as does the photo seen in figure 1.31. In this photo, we also see that there was a vertical crack at the front of the Sphinx's body, not far behind the head. An Arab is standing on the Sphinx's right shoulder. The three specks along the Sphinx's flank, which look as if they might be holes, are, in fact, Arabs. (*Collection of Robert Temple*)

Figure 1.34. An early photo of the Sphinx by W. Hammerschmidt, dated 1829. Just beside the rear of the horse on the left may be seen the large crack in the Sphinx's haunches leading to the shaft and the tomb below. (*Collection of Robert Temple*)

Let us see now how Hawass and Lehner describe the upper stage of the rump tunnel:

The upper part of the passage runs along the curve of the bedrock profile of the statue but is covered by large Phase I restoration blocks. These blocks are covered in turn by the thinner Graeco-Roman (Phase III) and 1926 masonry [put there by Baraize]. Without these layers of masonry, the upper part of the passage would be an open trench in the Sphinx core body. . . . The top [that is, the termination] of the passage is sealed off by the Phase I blocks and a large patch of modern cement. Although it is difficult to know for sure, it seems most likely that the Phase I blocks do not entirely seal off the passage. The cement probably spilled down into the passage from the filling of the space between the Phase I slabs and the bedrock core on the ledge of the masonry at the upper part of the rump, about 3 m. above the passage. 14

Figure 1 in the Hawass and Lehner article shows a drawing of the passage from above, and from this it is evident that the "cement fill" at the end of the upper part of the passage must extend for at least 6 to 10 feet. Such a massive filling of cement effectively destroyed the passage at that point and rendered examination of it nearly hopeless. What happened beyond that point is therefore unknown. There are no old Egyptian workmen left alive today who can shed any light on this, and 1926 was therefore the last time anyone was to have any opportunity to know the full story. Baraize really messed things up. And as we have already seen, it is only because of three old men in 1980 that the existence of the bottom part of this passage was ever known at all. If they had died earlier, the rump tunnel would have remained unknown forever. So near did we come to total ignorance. Instead, we are left today with only partial ignorance.

When we come to the evidence of 1715 and earlier, we will reconsider this matter of the tunnel that ends in a sea of cement, and whether in the period prior to its being blocked forever by Baraize the situation might have been rather different. Of course, we will have to keep an eye on just how much of the Sphinx was buried in sand at any given time. And because so much of it was buried for so long, the fact that the rump was effectively detached until 1926 is of particular importance, affording, as it may have done prior to 1926, a possible access route to the interior of the statue from above. And in connection with this idea, we have to keep in mind the proprietary interests of the inhabitants of Nazlet el-Samman, the Sphinx village, where a single family of local inhabitants may well have profited from this very route into the Sphinx, repeatedly covering and uncovering the entrance to the fissure when they had foreign customers who would pay for access. There are inhabitants of the same village today whose houses lie over important antiquities, such as Sabry Hatab, who, I am informed by local people, actually lives on top of the remains of the Valley Temple of Cheops! As he has no inclination to tear down his house, the temple remains officially unexcavated. It was discovered in recent years when a sewage system was installed for Giza. Perhaps Mr. Hatab will one day change his mind and decide to become a hero to archaeology.

We know about one end of the rump tunnel, although we can never properly know about the other. But what can we know about its origins? It is very interesting to learn that if the Phase I casing stones had not been laid over it, it would be an open channel. This means that the date of the Phase I casing stones takes on an even greater than usual importance. Whatever their date, they are later than the rump tunnel, since they are on top of it.

Hawass and Lehner are very clear about the Phase I casing stones. They say that there are two possibilities: either they date from the Fourth Dynasty of the Old Kingdom (circa 2500 BC) or they date from the Eighteenth Dynasty of the New Kingdom, a thousand years later. Hawass and Lehner are open to either possibility:

We might consider the possibility that the lower casing blocks are part of an earlier, IVth Dynasty, casing that finished off the lion body of the Sphinx. The three courses of Phase I casing next to the bottom course are thicker than the blocks immediately above them. . . . In profile, the lower veneer of large blocks looks like the masonry casing on Old Kingdom mastabas at Giza. . . . The blocks above the lower three or four courses are thinner, but they also have the appearance of Old Kingdom casing; the range of their thickness is matched by that of slabs forming the walls of the Khafre causeway where it meets the Valley Temple. . . . As mentioned, it is clear that the natural Member II bedrock of the core body [of the Sphinx] was severely weathered before the application of Phase I casing. The major obstacle in assigning Phase I to the IVth Dynasty as the finish work for the Sphinx body, is the Phase I masonry fills in the deep recesses caused by the weathering away of the softest beds.

It is also clear from a detailed study of the Sphinx chapel, located between the forepaws, that the earliest phases of masonry on the statue, including Phase I masonry on the chest and very large blocks behind the granite stela of Thutmose [Thutmosis] IV, are, in fact, XVIIIth Dynasty. At this time the Sphinx was excavated [having been covered up to its neck in sand for centuries], found in weathered condition, and its lion body reconstructed. The XVIIIth Dynasty restorers probably took the Phase I blocks from the Khafre causeway, in effect taking apart the monuments . . . to reconstruct the Sphinx as Horus-in-the-Horizon. <sup>15</sup>

Figure 1.35. A close-up of some of the restoration on the Sphinx. The central limestone blocks are believed to be of Old Kingdom date, from the first repair job, but modern cement has been smeared into the cracks between them. Above them have been laid modern limestone pieces, carefully fitted to the surface, and below, larger limestone blocks have been cut and inserted into holes where older blocks had fallen out and been lost. (*Photo by Robert Temple*)

Of course, if the Phase I casing blocks on the Sphinx were used to repair a weathered Sphinx body, as this report seems to indicate, and if those blocks were placed there in the Fourth Dynasty, then it means that the Sphinx is considerably older than the Fourth Dynasty. But at the moment, the orthodox view in Egytology is that the Sphinx was carved in the Fourth Dynasty and cannot possibly have needed repair of its weathering, since it was brand-new.

At the Eighth International Congress of Egyptologists in Cairo in March 2000, I attended a talk by Dr. Rainer Stadelmann, former director of the German Institute in Cairo. Dr. Stadelmann wished to discuss whether the Sphinx had been carved by Cheops or Chephren, which is a difference of only a few decades

at most. Such intense passion was aroused by this apparently insignificant point that Dr. Zahi Hawass rushed up from the audience onto the podium to say into the microphone that he differed from Stadelmann! He then proceeded to give a mini-lecture of his own while the hapless Stadelmann stood beside him, pointing out that the pharaoh could not be the one Stadelmann preferred, and that Stadelmann was hopelessly wrong. Stadelmann preferred Cheops, but Hawass insisted on Chephren, which frankly seems too small a difference to matter very much. But certainly passions ran high, and voices were raised over this small matter. What, then, would be the reaction to the suggestion that the Sphinx was not carved by either pharaoh, but was really older? Please do not think that I am one of the people who believes that the Sphinx is twelve thousand years old! I am certain it is not. But surely it is possible to have a legitimate opinion, without being shouted at, that the Sphinx may be older than both Cheops and Chephren, indeed may have been repaired by one of them with the Phase I casing blocks, while still being of an age that is rational and does not require theories of Atlantis to explain it.

However, judging from the fact that one cannot even suggest the "pharaoh next door" as a builder at a supposedly sober international scholarly conference without having the microphone grabbed out of one's hand and being told one is wrong, and having an impassioned counter-speech made beside one, to make a bolder suggestion would seem to be more than one's life is worth in Egyptological circles.

Before we leave the Phase I casing blocks that cover the rump tunnel, I should give my own opinions and those of someone whom I regard as the leading expert. Figure 1.35 is a close-up photo I have taken of these blocks, from which it may be seen of what good quality they are. They are really the finest possible limestone masonry, expertly prepared and laid, and so superior to all other blocks (including the most recent) on the Sphinx as to put the others to shame. I have no doubt that these Phase I blocks are of Old Kingdom date, as no one later than that had the skill to produce and lay such stones, in my opinion. It was quite beyond the capabilities of the masons of the New Kingdom's Eighteenth Dynasty. One only has to look at the pathetic Eighteenth Dynasty temple remains beside the Sphinx (the small ruined temple at a high level, since the Sphinx Temple was buried in sand then and only excavated later in the New Kingdom) to see the stark contrast in building capabilities. At least that is what I think. But I am not alone. I asked my friend Lal Gauri, the limestone expert who worked on the Sphinx with Hawass and Lehner, and he was inclined to believe that these stones were of Old Kingdom date, because of their remarkable quality of workmanship.

Now let us turn to the account of 1715 that reports entry into a chamber beneath the Sphinx. This is the first occasion in our times when documentary evidence has been presented that reports the discovery of such a chamber. In the next chapter, I reveal that many such reports have actually been published and discussed even up until 1953, but subsequently they have been systematically ignored because they did not fit the preconceived views of Egyptologists of the past half century, when consensus opinions have become far more ossified and intolerant than in the past, a sign of extreme decadence in the discipline of Egyptology as it exists today.

With all the books that have been written on the subject of the Sphinx since 1953, there has been no such evidence. Now at last we have real evidence, rather than merely the claims of a psychic in a trance, of the existence of an underground Sphinx chamber, and later we shall see that there is much more. Strangely enough, the evidence presented in this and the following chapter actually substantiates with a series of published eyewitness reports the "psychic reading" of Edgar Cayce concerning the Sphinx, at least insofar as he insisted on the basis of a psychic vision that there was an underground chamber there. We can now prove that he was correct about this general point. Although he "saw" a chamber in a different place at the Sphinx (and the existence of that one remains to be proved), he was correct in

insisting on the existence of an underground chamber at the Sphinx. The mistake his followers have made subsequently was to not even attempt to search for the material that I have found. But that is presumably because followers of Edgar Cayce do not tend to be scholars and do not know how to do this sort of thing.

In any case, scholars are a vanishing species these days, and as they all die off, they are not really being replaced, due to the collapse of the Western educational systems (in contrast to that of China, which retains rigorous standards of excellence in education that perversely decadent Westerners have thrown overboard) and the impact of the information deluge, which has drowned out serious research and replaced it with the ludicrous substitutes of Google and Wikipedia. Those Internet sources, as with all such information sources based on nonrigorous data supply, are riddled with errors and misinformation and are often worse than worthless, since there are no safeguards against their being incomplete, misleading, and frankly wrong. Barely anyone is being trained these days to do real research in information that predates 1990 and depends on printed or manuscript materials, so that in twenty or thirty years' time, there may not be a genuine scholar left alive anywhere on the planet. Then, the lack of the ability to discover the truth about anything will be one of the main precipitating factors that will contribute to a total collapse of what humans have struggled for millennia to create: something fast vanishing called "civilization."

The first passage we will now examine occurs in the English translation of 1715 of a book written in Latin and first published in 1599. On further research, I discovered that the account did not appear in the original Latin text at all, so that it does not go back to 1599, but first appears in print in 1715. It was some information inserted by the English translator himself. To give him justice, he does freely state at the front that his translation contains such additional material. But we are handicapped by a major problem: he is anonymous, and we have no idea who he was!

The book concerned is a curious one, about which I have already had a lot to say in my earlier book *The Crystal Sun*. It was originally written by the Italian antiquarian and polymath Guido Pancirollo (in Latin, Pancirollus), but he died before it could be published, and so his close friend, a noted German antiquarian, Henry Salmuth, edited the work, added much material of his own, and saw it into print in 1599. It was published in the obscure Bavarian town of Amberg. Its title in Latin was *Rerum memorabilium iam olim deperditarum & contra recens atque ingeniose inventarum: Libri duo*, the translation of which was entitled *The History of Many Memorable Things Lost, Which Were in Use Among the Ancients: And an Account of Many Excellent Things Found, Now in Use Among the Moderns, Both Natural and Artificial*, and it was published at London in 1715 and reissued in 1727. I am fortunate to own a copy of this book in translation.

Since it is the translator of this book who tells us about the underground Sphinx chamber, as I shall describe in a moment, it is galling that he suffered from an overdose of modesty and refused to identify himself. That he was no humble clerk but rather an eminent and witty scholar is evident from his four-page "Preface of the Translator." This man regales us with his encounter with a pompous Oxford scholar whom he then lampoons. He heaps praise on the "genius" Robert Boyle and speaks of the contemporary scholar Mr. Glanville as if he were his equal. He then confidently says of Salmuth's annotations to the book: "I have par'd off the Excrescences of his luxuriant Style, and have pick'd out of his Notes the most pat Illustrations; to which I have added some Histories of my own, and some Observations and Remarks, such as I have met with in my slender Reading, and which I thought agreeable to the Argument in Hand."

These are not the comments of an unaccomplished man; they are the assurance of a man who knows his own worth in the scholarly field and seems to be a man of science of some kind. He must have been a person of note in his time. On the title page he further explains, or his publisher explains for him: "Now

done into English, and illustrated with a new Commentary of choice Remarks, pleasant Relations, and useful Discourses, from Salmuth's large Annotations; with several Additions throughout." And further: "To this English Edition is added, First, A Supplement to the Chapter of Printing, shewing the Time of its Beginning, and the first Book printed in each City before the Year 1500. Secondly, What the Moderns have found, the Ancients never knew: Extracted from Dr. Sprat's (late Bishop of Rochester) History of the Royal-Society, the Writings of the Honourable Mr. Boyle, the Royal-Academy at Paris, &c."

Among the large "Additions throughout" are the comments on the Sphinx chamber, which appear to come from what the translator wittily calls his "slender Reading," which we can be sure was anything but slender. But alas, what could be the source on which he drew? It has never come to anyone else's attention. But, then, this book itself has never come to anyone's attention either. Not any modern person concerned with Sphinx chambers, I mean.

Here, then, is the brief and tantalizing description of an underground Sphinx chamber given by this 1715 translator:

I imagine this Sphinx to be a Sepulchre, but we cannot understand how it belong'd to Amasis [the Greek name of a pharaoh whom he mentioned earlier, said by Pancirollo to have constructed the Sphinx], for all the Records and Traditions of this Sphinx are lost. That it is a Tomb, may appear, 1. By its Situation, which is in a Place, which was in former Ages a Burying-Place, and near the Pyramids and mortuary Caves. 2. It is to be imagin'd that it was a Sepulchre from its building. In the hinder Part is a Cave under Ground, of a Bigness answerable to [an eighteenth-century expression meaning "comparable to"] that of the Head, into which the curious have look'd, by an Entrance that leads into it; so that it could serve no other Purpose but to keep a dead Corps [corpse] in, as Travellers inform us.

Earlier, Pancirollo (page 104) specifically states that the circumference of the head of the Sphinx is 102 feet. (Incidentally, he also says its body is not that of a lion but of a marmoset!)

Here we have a puzzle and several problems. The translator has not himself seen this Sphinx chamber, but has taken the description of it from "Travellers." There were indeed many accounts written by travelers prior to 1715, but which travelers? We are not told, and if they were the well-known ones, someone would have noticed an account of the chamber, surely. However, I realized that at least one such clear account must exist. I was certain that otherwise our translator would not have made this statement so confidently, especially as he does so not to impress us with the mysterious existence of a chamber, but to support his belief that the Sphinx contained a tomb. The translator does not give any indication that he thinks the existence of a Sphinx chamber anything at all unusual; to him it is merely another detail of the monument that he takes for granted, and his passing reference to it in the context of an argument gives us no reason to believe that he made this up. We are left, then, with the enigmatic description and must try to account for it.

The first thing that bothers us is that the size of the chamber is comparable to the size of the head, which the same book states to be 102 feet in circumference. The "den" at the end of the Sphinx's rump tunnel into which I crawled is hardly of that size! It may be perhaps 12 feet (4 meters) in circumference.

Then there is the problem of access. In the early nineteenth century, the Sphinx was covered up to its neck in sand. So how did the travelers prior to 1715 get into anything at all at the rear of the Sphinx, much less a chamber? Here, however, we remember the fissure shown in figures 1.31 to 1.34 and the possibilities of entering the body of the Sphinx by squeezing down it prior to 1926, or at least prior to

1817, when Henry Salt began blocking up entrances into the Sphinx, as described later. Since the top of the Sphinx's back was easily reachable, if this upward tunnel prior to 1715 broke through to the surface, which is highly possible, "the curious" might have descended into it as a matter of course on their visits to the Sphinx. And this would take them inside the Sphinx's rump. This therefore leads us to the possibility that there may be another and larger chamber beneath the Sphinx's rump, perhaps farther forward, reachable from the upward tunnel by a different route that has long been blocked up and in modern times has not been unblocked. Even before the entire area was filled and thoroughly smeared with cement by Baraize in 1926, it is most likely that there was a concealment by some family of local tour guides, as I suggested a moment ago, of some special entrance into this fissure. For the extremely poor local inhabitants, to have even a single private trick to offer the discerning tourist might make the difference between eating for a week or going hungry. All of us who know Giza at all well know the truth of this. Any Giza taxi driver (and to call them loquacious is the understatement of the year) will explain to you in five minutes that if he loses a fare, his family cannot eat. Allowing for bravado and exaggeration—and there is plenty of that—the realities of life in Cairo are that if you are not rich, you are very, very poor. And being poor in Cairo is a form of desperation no Westerner would ever wish to experience, since such poverty in the West did not even exist in living memory and is incomprehensible to most people. I am talking about people who cannot afford shoes, who cannot buy soap, who can barely eat enough to live. When Olivia and I have given cheese sandwiches to beggar children at Giza, we have been horrified at the savage animal ferocity with which they crammed them into their mouths, not even chewing as they desperately gulped, with wild, staring eyes, anxiously worried that another child would try to grab a crumb from their very lips. In such a society, the possession of the secret of a single stone blocking an entrance to a single passage can mean the difference for an entire family between gnawing hunger and desperation and a feeling that life is worth living.

Apart from the rump tunnel and its upward annex to parts unknown, there are other Sphinx passages and entrances. Figures 1.36 and 1.37 are photos of the location of the entrance to a passage at the base of the Sphinx on its north side. The modern masonry was put there by Baraize, who walled up the passage in 1926. This one has not been unblocked, and we have absolutely no record of how far it extended, whether it went up or down, or anything at all other than the fact that two men could stand inside, as there is a surviving photo in the possession of the archaeological authorities showing a workman inside it in 1926 before it was closed. Hawass and Lehner speak of this passage as follows:

Figure 1.36. This is the entrance to a tunnel entering the northern side of the Sphinx, which was blocked in 1926 by Baraize using stones that he found in the vicinity. No one has any idea what is inside. It would be an easy matter to pull out these stones and see what lies behind them. The height of this doorway can be judged from the photo in figure 1.37 below. This photo shows the full width. The exploration of this Sphinx tunnel should be a matter of the highest priority. (*Photo by Robert Temple*)

Figure 1.37. Olivia Temple stands against the modern blocks that seal the tunnel opening in the northern flank of the Sphinx. This tunnel was opened in 1926 by Baraize, who then sealed it again firmly with these cemented blocks. He did not bother to leave an account of what he found. No one has opened it since. This large and obvious opening clearly led into the interior of the Sphinx's body, but no one ever bothers to wonder what it led to or why. (*Photo by Robert Temple*)

Several of the Archive Lacau photographs that document the excavations of the Sphinx during 1926–1928 show another spot where it appears that there might be a passage cut in and under the Sphinx. Arch. Lacau photos CI 17–20 show the north flank of the Sphinx when Baraize cleared the debris down to the floor level in 1925. The workers found a large number of Phase I—sized blocks toppled about in the debris at the base. CI 19 shows a close view of the base of the north belly where they found a large gap in the Phase I casing. A man is standing below the floor level in what may be a niche cut into the bedrock core body; another man stands on a small mound of sand just outside the gap. We identified this same spot on the basis of fissures showing in the core body above the casing. It is sealed off now by large stones, some of which are replaced Phase I slabs, sealed with grey cement [which is what Baraize used]. . . . It is possible that the passage in the north side of the Sphinx, like that at the rump, is ancient. 16

It is interesting that this passage too had been covered by the early Phase I blocks, some of which Baraize put back in place and cemented, since this indicates an early date for this feature as well. The sealing of this passage has been accomplished so solidly that a major effort would have to be made to reopen it, and a decision was obviously made not to do so. Perhaps the passage will be reopened one day, especially in light of the information from the 1715 source, and the others to be discussed later, that there must be a chamber somewhere under the Sphinx, and any of the known passage entrances is a candidate for leading to it.

I tried very hard to locate the Lacau Archive photos mentioned by Hawass and Lehner, and it was with the greatest difficulty that I finally discovered where they were in Paris, in an obscure outlying facility of the Institut des Hautes Écoles called the Centre Golenischeff, which has a small Egyptological library. I made an appointment by telephone to go and see them, but when Olivia and I turned up at the library in Paris, we were refused access to the photos. We saw a door marked Archive in the library, but

the girl would not admit us to it, although she let us look at books on the open shelves. She said her boss, Professor Christiane Zivie-Coche, wanted to know why we wanted to see the photos. Zivie-Coche has written a brief book about the history of the Sphinx. The girl said the photos were "in boxes," but then most archive photos are in boxes! What else would they be in? The girl, Nathalie Toye, who was Zivie-Coche's student and writing a thesis on New Kingdom stela prayers, gave me Zivie-Coche's e-mail address and said I would have to write to her to explain why I wanted to see the Lacau photos. When I complained that I had come from London with an appointment, she showed no concern that it was a wasted trip and that the appointment mutually agreed in advance had not been honored. There were drunks, who had mattresses and slept beneath the library, shouting beneath the windows, making the atmosphere even less pleasant in that not exactly thrilling part of Paris called Glacière. The library was actually housed in a student residence building, and to get to it from the street, you had to step around overflowing rubbish bins that stank. I sent an e-mail to Zivie-Coche when I returned to London, and she replied by e-mail dated 21 September 2007 refusing me access to the Lacau photos on the excuse that they were in boxes, but then going on to make clear that her real reason was that "we do not share the same way in analyzing the egyptological [sic] questions." She added: "I do not doubt that you worked on the question of the Great Sphinx so did I and so did Mark Lehner who is a [sic] excellent scholar and archaeologist with whom I worked on the spot." In other words, access to the Lacau photos was to be restricted to Lehner, Hawass, and Zivie-Coche, and to those who agree with or sympathize with them. My reply to her was as follows:

Dear Madame, I am very disturbed by your email of 21 September. I am certain that Pierre Lacau would not have approved of your restricting access to his photos only to people who share your opinions. The Institut des Hautes Écoles would certainly not be in agreement with restricting public materials to private purposes. There is something called the community of scholars. Members of that community are meant to share information, not conceal it, especially information which was not originated by them.

No further reply was received. So, alas, I was unable to see the three Lacau photos showing the north side of the Sphinx during Baraize's excavations. Zivie-Coche, on the other hand, did not hesitate to reproduce seven of the Lacau photos in her own small book on the Sphinx, none of them with any copyright indicated, so they are all clearly in the public domain. The Lacau photos are therefore readily available for use by Zivie-Coche herself, but cannot even be looked at by anyone who "does not share the same way," to use her words, which presumably includes her theory recorded in her book: "I shall content myself with stating that the Sphinx was modeled as a gigantic image of Chephren." As we shall see in chapter 4, the face of the Sphinx does not look anything like the face of Chephren (see figure 4.7) and is most definitely not "a gigantic image of Chephren." In chapter 4 I reveal which pharaoh's face it really is. Zivie-Coche and I therefore certainly do not "share the same way." Whether Zivie-Coche has abused her academic position by giving access to photos that are under her control to herself and her friends while denying access to those who disagree with her theories is for others to decide.

Hawass and Lehner also point out that there are old photos of 1925 (doubtless further Lacau photos, though they do not specify this, and Zivie-Coche's refusal to allow me access to them means that I cannot check) showing evidence of "another large gap" near the base of the Sphinx masonry inside the large masonry box on the south side of the Sphinx. This may have been an opening to yet another Sphinx passage, but nobody can be sure today, for, as they say: "By the time of our work at the Sphinx in 1979, the gap was closed by limestone patching with modern mortar." Baraize and his cement again! Indeed,

one is tempted to view Baraize as a truly manic passage-sealer.

Hawass and Lehner do not mention the small underground chamber in front of the Sphinx, in which it is possible to crouch, and which is also sealed up, so we do not know whether it once led anywhere either. This little cell is now covered with a modern grille, and it is easy for anyone to see when you visit the paws of the Sphinx. The entrance hole to this cell is seen in figure 1.29. So what with all of these passages and entrances that lead nowhere today, one could be forgiven for being somewhat bewildered.

This brings us to the subject of the accessibility of the Sphinx and at what dates it was or was not covered by sand. In other words, if people were routinely entering a chamber beneath the rump of the Sphinx as reported in 1715, how were they doing this if there was too much sand to permit their reaching the base?

Other old photos of the Sphinx from my large collection, which are reproduced as figures 1.31 to 1.34 also clearly show the exposed crack in the haunches at the rear through which entry to the passages could still have been possible prior to 1926.

This matter of the gap in the haunches is certainly an interesting conundrum. And it brings us back again to the question of the upward tunnel in the rump, for if that tunnel really does or did emerge at the top of the back, or if another similar tunnel did emerge, then the underground chamber was reached not from the bedrock level but from a tunnel going down through the Sphinx's body from its back, and thus theoretically accessible for most of the period of the Sphinx's existence. That local people informed Hawass of the existence of the rump tunnel is also suggestive: it clearly implies what I have said, that local guides kept as a trade secret the existence of that tunnel, its "den," and its associated upward tunnel. But how did they first learn of it? And what other such tunnels and chambers may not have been revealed to any archaeologist, contrary to the way this one was revealed to Hawass? If people were entering the underground chamber beneath the Sphinx prior to 1715, they were certainly paying some very good baksheesh to whoever had the secret of how to enter it.

What, then, of this matter of the sand covering the Sphinx? The fact is that we do not have reliable information about all the periods when the Sphinx has been freed or partially freed from sand. The first full and reliable accounts we have of this problem date from 1817, as I shall describe in a moment. The Sphinx was said to have been covered with sand to the level of the head in 1798 when the Napoleonic troops of France invaded Egypt. As is explained in the next chapter, there was actually a partial clearance before they arrived, a fact that was forgotten until I discovered the evidence of it in an unpublished manuscript source. It is normally assumed that the Sphinx had been untouched for centuries before the arrival of the French, and that is doubtless how the French would like the story to be told, because it enhances their glory, and the French are always very keen on la gloire. However, by bringing this correction to the historical record in the next chapter, I do not mean to disparage the achievements of the French. Napoleon sent a large group of scholars (known as the savants, or wise men) to Egypt with the troops, who spent many months carrying out detailed surveys and studies of all kinds, which were later published in Paris in a series of famous and massively illustrated volumes. 20 We know that they cleared some sand from the Sphinx, but apparently not much. Of this expedition, the British colonel Howard Vyse wrote in 1840: "The French are not supposed to have made any considerable excavations or discoveries about the Sphinx, which was opened by Mr. [Henry] Salt and M. [Captain Giovanni Battista] Caviglia in 1817; but it appears that when Dr. Whitman saw it [in 1801], some of the sand had been removed, as he describes the substructure, although he did not perceive the body of the image."<sup>21</sup>

In his book *Pyramid Facts and Fancies*, James Bonwick gives some information that makes the history of visibility of the Sphinx even more complicated. He has a short section about the Sphinx in

which he points out that more of the Sphinx was visible in 1705 than in 1877, and presumably also more than was visible to Napoleon's scholars in 1798: "The head only appears above the sand at present [1877]. A picture in *Harris's Voyages*, about 1705, gives far more of the head than can now be distinguished. The wings, as they are called, behind the ears [he means the hanging folds of the nemes headdress, which are known as "lappets"], are very distinct, as well as the eyes, ears, and chin."<sup>22</sup>

In figure 1.46 we reproduce this illustration (which Harris had republished in 1705) in its original form, as it appeared in the 1611 book by George Sandys, which describes Sandys's visit to Egypt in 1610. The full text of Sandys's account of the Sphinx is given along with other early travelers' descriptions in part 2. The men riding on asses toward the Sphinx with harquebuses (old-fashioned rifles) over their shoulders are Mameluke soldiers, sent to escort and protect the European visitors to Giza from the dangerous locals, who might attempt to rob them. At this time, no trace of the Sphinx's body was visible.

Figure 1.38. A nineteenth-century engraving by M. Kurz from a drawing done by A. Löffler showing the Sphinx largely buried in sand, which was prepared not for a book but as an engraving for separate sale in Germany at an unknown date. I purchased it from a German dealer; it is entitled "Sphinx und die Pyramiden." (Collection of Robert Temple)

Figure 1.39. The Sphinx in the middle of the nineteenth century, with only the desolate desert and sand dunes between it and the Pyramid of Chephren in the distance. The sand has already filled in again at the Sphinx's chest, following Caviglia's 1817 excavation of that area. The extreme erosion and poor condition of the left (north) side of the Sphinx is clear here. That has all now been covered over by "repairs." The great crack in front of the rump is seen here as a dark vertical streak in the side, as its top has been covered by windblown sand. The rear of the Sphinx, which was perfectly clear in 1827 (see figure 2.10), has now been swallowed by sand again. (*Collection of Robert Temple*)

Figure 1.40. A Victorian photo of the Sphinx, showing the sand engulfing it on the north. In other Victorian photos, the sand is engulfing it from the south. (*Collection of Robert Temple*)

Figure 1.41. This old Victorian glass slide of the Sphinx shows that an ocean of sand has engulfed the south side of the Sphinx and that the mound on top of the Valley Temple has risen as high as the Sphinx's chin. After Caviglia cleared the space in front, this deluge of sand swallowed up the right leg again. (*Collection of Robert Temple*)

Figure 1.42. A Victorian glass slide, probably dating to the 1870s or 1880s, showing how the sand was reinvading the Sphinx after Caviglia's excavations. A man is sitting on top of the Sphinx's head, and another stands on top of the Dream Stela. It is clear from this photo how impossible it was to get an idea of the north side of the Sphinx (at right) prior to its excavation by Baraize in 1926. (Collection of Robert Temple)

Figure 1.43. Here is a Victorian glass slide of the Sphinx taken from the northeast and showing the height of the sand to the north of the statue. (Collection of Robert Temple)

Figure 1.44. This glass lantern slide from the latter half of the nineteenth century shows what was visible and accessible of the Sphinx at that time. Most of the clearance at the front, done in 1817, has now filled in again with sand. The ragged nature of the left lappet of the headdress is very evident here, in silhouette against the sky. This photo gives a clear indication of the severe crack behind the Sphinx's shoulder, which is filled in today with cement. The more serious crack at the rump is just visible at the edge of the photo. (*Collection of Robert Temple*)

Figure 1.45. A Victorian glass slide of the Sphinx from the southeast, taken from the mound that still covered the Valley Temple.

The Great Pyramid is in the background. (*Collection of Robert Temple*)

Figure 1.46. This is how the Sphinx looked in 1610, just a head and neck sticking out of the sand (at left). This engraving appeared in the book by George Sandys, A Relation of a Journey Begun An. Dom. 1610, London, 1615. (Collection of Robert Temple; I am descended from George's uncle Myles Sandys.)

Figure 1.47 is a contemporary drawing of the Sphinx as it appeared during Caviglia's perilous and daring excavations, when many of his men were threatened daily with being engulfed with sand. The Sphinx emerges from its surrounding element rather like a whale coming up for air. A description of Caviglia's immense feats makes for interesting reading:

He first began to open a deep trench on the left, or northern side, opposite the shoulder of the statue; and, though the sand was so loose, that the wind drove back frequently during the night more than half of what had been removed in the day, yet he managed by the aid of planks, arranged so as to support the sides, to dig down in a few days to the base. The trench, however, being no more than twenty feet across at the top, and not above three feet wide at the bottom, the workmen were evidently placed in a dangerous situation; for if any large body of sand had fallen in, it must have smothered those who were employed below. It was, therefore, found necessary to abandon this part of the attempt. By what had been done, however, the height of the statue from the top of the head to the base was ascertained, and it was also found that the external surface of the body was composed of stones of various sizes, put together with much care. The form of the masonry was not very regular, but it consisted of three successive ledges, sufficiently broad for a man to stand upon, to represent the folds of a mantle or dress. It seemed to have been added by the Romans.

Figure 1.47. This is Henry Salt's drawing of the Sphinx being excavated by Giambattista Caviglia in 1817. The most threatening mountain of sand was on the north side (to the right in this picture). In 1926, Baraize was so worried about the sand engulfing the monument from the north that he built the barrage walls seen in the aerial photo figure 6.50. It was not until 1937, 120 years after the scene here, that the problem of the sand to the north of the Sphinx was solved by Selim Hassan, with his armies of laborers and rail carts (see figures 3.11 and 3.12). This illustration is from *Operations Carried On at the Pyramids of Gizeh in 1837* by Colonel Howard Vyse and John S. Per-ring, 3 vols., London, 1842, appendix volume III, opposite page 107. (*Collection of Robert Temple*)

The result of the first operation not proving satisfactory, Captain Caviglia began a large excavation towards the front, in which he employed, from the beginning of March to the end of June, from sixty to a hundred labourers. Many interesting discoveries were now made. Among other fragments that were found, were portions of the beard of the Sphinx, and the head of a serpent. [This beard of the Sphinx was not original but was stuck on in the New Kingdom, as will be discussed later. These four fragments are seen in figure 3.1, as drawn at the time by Henry Salt. As for the serpent, this was the head of the royal uraeus emblem (insignia of a serpent rearing its head) on the Sphinx's forehead.] Most of these lay in a small temple, ten feet long and five feet broad, which was immediately below the chin of the statue. . . . A large part of the left paw was uncovered, and the platform of masonry was found to extend beyond it. In the course of a fortnight Captain Caviglia had removed the sand from the paw, and from the outer walls of the temple, in front of which was an altar formed of granite. It is now in the British Museum, and has had at the angles projecting stones, which may be supposed to have been called the horns of the altar. This fragment still retains the marks of fire—the effects, probably, of burnt offerings.

Captain Caviglia succeeded in laying open the base of the Sphinx, and in clearing away the sand in front of it, to the extent of more than a hundred feet. Many short Greek inscriptions were indistinctly cut on the paws of the statue. [These can no longer be seen, as the paws have modern masonry covering them as a result of restoration efforts. Later, we shall see that an inscription carved into the middle toe of the left paw contained some important evidence about the original purpose of the

Sphinx.] They prove that the image was held in high veneration. . . . It is scarcely possible for any person, unused to occupations of this kind, to form an idea of the difficulties which Captain Caviglia had to surmount when working at the depth of the base; for, in spite of all his precautions, the slightest breath of wind or concussion set the surrounding particles of sand in motion, so that the sloping side crumbled away, and mass after mass tumbled in, till the whole moving surface bore no unapt resemblance to a cascade of water. Even when the sides appeared most firm, if the labourers suspended their work only for an hour, they found that the greater part of their labour had to be renewed. This was particularly the case on the southern side of the right paw, where the people were employed for seven days without making any sensible advance, because the sand rolled down in one continued and regular torrent as fast as it was removed. He therefore only examined the end of the paw. . . . At the distance of about two feet to the southward of the right paw, the platform abruptly terminated. It was therefore supposed that the Sphinx was placed upon a pedestal; but, by extending the operations in front of the statue, the platform was found to be continued, and the steps were discovered. . . . Such was the result of Captain Caviglia's exertions in June, when, in consequence of exposing himself too much to the sun, he was unfortunately seized by an attack of ophthalmia [sunstroke], that compelled him to suspend his operations.<sup>23</sup>

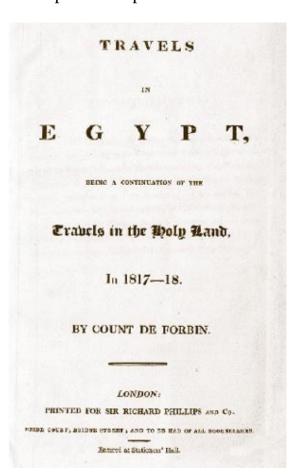

Figure 1.48. The title page of Count de Forbin's *Travels in Egypt, Being a Continuation of the Travels in the Holy Land, In 1817–18.* 

These heroic exertions give us a vivid impression of just how difficult it was to clear the Sphinx so that its body could be seen at all. A contemporary visitor's account of this operation was written by the French Count de Forbin:

The colossal sphinx still rises thirty-eight feet above the sand that the winds from the desert are accumulating about it. My arrival was too late to avail myself of the labours of M. [Henry] Salt

[British consul general at the time, who worked with Caviglia]. On clearing away about the base of this statue, he had found steps that communicated with the gates of a little temple erected between the feet of the sphinx. An unpardonable egotism led him to block up again objects which call for an active and vigorous investigation, which would throw great light on the history of the arts in ancient days, would bestow éclat on one of the most sublime monumental fictions to be found in ancient Egypt.<sup>24</sup>

This is a shocking eyewitness report that Henry Salt, through obstinacy and egotism, "block[ed] up" things at the Sphinx that should have been the subject of "an active and vigorous investigation." What does "block[ed] up" mean? It can only refer to openings and passages, and since the plural is clearly used, he must have done this to more than one. We are talking here of blockages made more than a century before Baraize. One of them certainly must be the blocked passage in the small underground chamber now covered with a metal grille beneath the face of the Sphinx. Since Count de Forbin is so adamant about it, we must presume that there was indeed an actual passage here that led away in some direction or other, which to us is unknown. Count de Forbin must have had an argument with Salt about it, insisting that someone should crawl along the passage and see where it went, but Salt couldn't be bothered and "dealt with the situation" in the manner of a diplomat, simply by sealing the damned thing off and settling the matter by brute force, a tactic of "block-and-run."

But as one of the blocked entrances may be identified, what could be another? Possibly Count de Forbin is referring to the one on the north side of the Sphinx that Baraize cemented over in the 1920s; Baraize may have opened it, had a look, and then resealed it as he did the rump tunnel. Or there may well be at least one completely different passage, of which we have no idea, or possibly several.

The blocked passage beneath the Sphinx's head is probably the answer to how the oracles were given by the Sphinx. The voice didn't actually come out of the head or mouth of the Sphinx, which was too high up to be heard easily, but out of the tiny chamber beneath the mouth at ground level, suitably obscured by a screen or even a cloth. The surviving little chamber is too cramped for a priest to crouch in for long, so he must have entered from the tunnel that Salt sealed up. But where was the entrance to this tunnel? Quite possibly it led from the northern side entrance sealed up by Baraize.

I have so far found one piece of evidence from an early traveler of the seventeenth century specifically mentioning a tunnel beneath the face of the Sphinx. There are many early travelers' reports, which we shall consider later on, that relate the local people's tradition that a tunnel led from the Sphinx to the Great Pyramid. But only one of these gives the additional detail that the tunnel of which this was claimed was, as the traveler puts it, "under the neck":

The upper part [of the Sphinx] remains above the sand; the lower part, on the contrary, is entirely covered. If it be true that the rest, or the lower part, is proportionate in size to the upper part, one must consider that it is one of the Seven Wonders of the World, for it seems to be cut from one piece of stone. Some people ask themselves if this stone colossus was cut from a natural rock in situ, or if it had been carried here from elsewhere. Plenty of people have wanted to examine it by excavation but they could not because of the sand. Others thought that this monster consisted of nothing more than half a body, for under the neck there is an opening of a stone tunnel which passes across the mountain of sand up to the pyramids, where it ends. <sup>25</sup>

This evidence from Father Antonius Gonzales, who visited the Sphinx in 1665, is highly specific. We need not accept the story that the tunnel went as far as the pyramids, but we must accept the likelihood that there was indeed an opening of a tunnel "under the neck" of the Sphinx, and this most probably is one of

the things blocked up by Henry Salt that so enraged Count de Forbin.

At the very least, in light of this evidence, the blocked passage in the tiny chamber beneath the face of the Sphinx should be opened. This should not be very difficult. Salt is unlikely to have had the resources that Baraize had to enable him to pour vast quantities of cement into the Sphinx. Salt's blockage would probably be easy to unblock. And if this is ever done, we can thank Count de Forbin for the prompting that led us to rediscover whatever it is that may be found. Even if the passage leads only a short distance, it could provide the answer as to how the oracles were delivered at the Sphinx.

The clearance by Caviglia and Salt did not last long. A mere seventeen to eighteen years later, on December 31, 1835, the Sphinx was visited by John Lloyd Stephens, who recounted: "Next to the pyramids, probably as old, and hardly inferior in interest, is the celebrated Sphinx. Notwithstanding the great labors of Caviglia, it is now so covered with sand that it is difficult to realize the bulk of this gigantic monument. Its head, neck, shoulders, and breast are still uncovered; its face, though worn and broken, is mild, amiable, and intelligent, seeming, among the tombs around it, like a divinity guarding the dead." <sup>26</sup>

It is often difficult to construct a reliable picture of what portions of the Sphinx were exposed or accessible at which dates. Just as one thinks one knows what the status was at a certain period, an unexpected piece of evidence comes to light that gives one a shock. For instance, I had assumed that during the period when Napoleon's expedition was in Egypt commencing in 1798, the Sphinx was covered in sand up to its shoulders and nothing else was visible. However, I then unexpectedly came across a passing remark that stated that the French at that period had cleared only the back of the Sphinx. But I had not known that they had done that, and I don't believe anyone else today had realized it either. I found this in an anonymous article in the *Quarterly Review* for 1818: "The Arabs . . . told to Mr. Caviglia, that the French had discovered a door in the breast of the Sphinx, which opened into its body, and passed through it to the second pyramid. The French never uncovered more than the back of the Sphinx." 27

While still surprised at this, I then came across another account, published eight years earlier, which gave the French credit for doing much more:

Upon the south-east side [of the Great Pyramid] is the gigantic statue of the Sphinx, the most colossal piece of sculpture which remains of all the works executed by the Antients. The French have uncovered all the pedestal of this statue, and all the cumbent [i.e., recumbent] or leonine parts of the figure; these were before entirely concealed by sand. Instead, however, of answering the expectations raised concerning the work upon which it was supposed to rest, the pedestal proves to be a wretched structure of brick-work, and small pieces of stone, put together like the most insignificant piece of modern masonry, and wholly out of character, both with respect to the prodigious labour bestowed upon the statue itself, and the gigantic appearance of the surrounding objects.<sup>28</sup>

This even more unexpected discovery appears to lead us to the conclusion that the French in about 1798/1799 may possibly have cleared the Sphinx entirely, and that less than two decades later it was all covered up again practically to the neck, so that in 1817 Caviglia had to clear the whole thing again. Although this at first seems unlikely, when we remember that Stephens tells us that less than two decades after Caviglia, the sand was back and the Sphinx was once more covered up to its shoulders, we see that the process merely repeated itself in the same length of time. It must have been an era of high winds!

In fact, the French clearing of the Sphinx must have been an incompetent effort, because a report by

William Hamilton proves that the sand had blown back again within a period of between three and ten years. The French clearance of the monument was in 1798 or 1799, and William Hamilton first visited Egypt in 1801, the year the French left. His book *Aegyptiaca* was published in London in 1809, so it cannot describe anything later than 1808. Here is what he says in his book: "The French excavated the body of the lion; which they found uninjured: but the sands of the Desert very soon rendered their labour vain, and the last time I saw the sphinx, the head and neck alone were visible. These have been evidently painted all over, and many characters are to be traced upon the head-dress [which are all gone today]."<sup>29</sup>

It is important to try to figure out how much of the Sphinx was exposed at any given time when we evaluate the meaning of various travelers' reports about doorways and passages. If anyone says he saw a chamber, could he really have done so? Was there anything sufficiently exposed to enable him to have access to any chamber?

By going through the early reports, I have now found a sufficient number of accounts tallying with one another to put together a proper case, and we shall be considering it in detail as we progress. We will see clearly that we are not left relying upon a single account that may be either unreliable or a mere fantasy. Various patterns emerge in the accounts when one compares them. And these in turn can sometimes even be supplemented by genuinely ancient evidence. To give a single example of this, let us consider whether there is any ancient account that suggests that there might be a "door" or entrance in or near the Sphinx leading underground. As it happens, there is. This ancient text is cited by the famous excavator of the Sphinx, Dr. Selim Hassan. It comes from the *Book of the Dead*. At the time those funerary texts were written, the Sphinx was called Ruti. In chapter 41, line 2, we read: "O Atum, I was rendered shining before Ruti, the Great God, who opens the door of Geb."<sup>30</sup>

Geb is the god of the Earth. Consequently, we have here a genuinely ancient text that speaks of the Sphinx opening the door of the Earth.

In his translation of the *Book of the Dead*, Renouf does not use the proper name Ruti, but uses the word in its meaning of "lion"; he also gives the name of the Earth god in its variant form of Seb and Atum in its variant form of Tmu: "O Tmu, let me be glorified in presence of the god in Lion form, the great god; that he may open to me the gate of Seb."<sup>31</sup>

Sir Wallis Budge, in his translation of the text, also does not use the name Ruti, but in his case he assumes that Ruti is a "double-lion god," because of the old pictures showing a kind of double-lion facing each way (see figure 1.49 below), also known by the name of Aker, the double-form being known as the Akeru (which is plural). Budge also uses Seb instead of Geb and Tem instead of Atum: "Hail, Tem, I have become glorious (or a *Khu*) in the presence of the double Lion-god, the great god, therefore open thou unto me the gate of the god Seb. I smell the earth. . . . I advance into the presence of the company of the gods who dwell with the beings who are in the underworld."

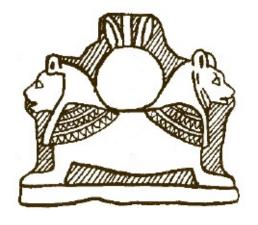

Figure 1.49. The double-headed lion facing both ways, symbol of the netherworld, which one enters by the eastern mouth as a corpse and leaves from the western mouth as a glorified spirit, called in Egyptian an *akh*, if one is lucky! (Many are the decapitated spirits of the damned that rumble forever in the stomach of this, the Earth Lion, screaming in agony as demons torment them in unspeakably vile ways.) This drawing comes from Selim Hassan's *Le Sphinx*, Cairo, 1951.

Figure 1.50. The Sphinx and the Pyramid of Chephren silhouetted at sunset, a view not seen by the public for a generation, as the Giza Plateau is locked long before this hour. (*Photo by Robert Temple*)

So we see that this passage clearly refers to a door of the Earth god that leads into the underworld and that appears to be at the Sphinx. It is certainly suggestive, and in the following chapters we shall have plenty of opportunity to see just how much it may mean.

## THE "SECRET CHAMBER" BENEATH THE SPHINX

The "secret chamber" beneath the Sphinx is not secret at all. It was known about for centuries, but forgotten in our own time. It was last described in print in 1953. Countless subsequent speculations about secret chambers beneath the Sphinx, and a book on the subject that was actually entitled *Secret Chamber*, have all been published without anyone having any recollection or knowledge of the many accounts of the *real* secret chamber that have appeared in print since 1672. Published accounts of the chamber beneath the Sphinx appeared several times during the 281 years that elapsed from the first to the last mention of it.

It certainly doesn't look very good that people have written so much about this subject without knowing anything about the plentiful evidence!

We shall see that the location and measurements of the shaft are known, along with the existence of an apparent burial chamber, which was entered by several people. But no one today who claims to be an expert on the Sphinx knows anything about it. Published reports on the subject that appeared over the course of more than two and a half centuries have therefore remained unknown, as if they had never been published.

I must make it clear that we are not here referring to the rump tunnel and the hollow in the rock at the bottom of it, all of which I have discussed at length in the first chapter. We are now considering instead the vertical shaft that was driven down into the Sphinx at about the point where the hips join the body—a shaft wholly filled with cement by Baraize in 1926, as I described in the previous chapter.

The first person to describe the shaft and burial chamber was the German traveler Johann Wansleben, often called Father Vansleb by the French and the English because the letter *W* in German is pronounced like a *V*. Sometimes his name has been misprinted *Vausleb*. A partial English translation of his account was published in London in 1678, with the title *The Present State of Egypt*. (I reproduce in figure 2.1 the title page of my own copy of the 1678 English edition of this book, where the author is called "F. Vansleb," the "F." standing for "Father." I also reproduce as figure 2.2 the relevant page of his book that contains his comments on the Sphinx.) I have also translated Wansleben's original account from German, as we shall see. The shaft and the chamber were next visited by an Englishman from Devonshire named Ellis Veryard in 1678, presumably stimulated by Wansleben's book, and Veryard then published his own account twenty-three years later, in 1701. In 1715, the anonymous translator of Pancirollo mentioned the subject in the book that was described in chapter 1. His description was lifted directly from Wansleben's book, as may be seen by a comparison of the wording. In 1721, the Englishman Thomas Shaw visited the Sphinx and mentioned the shaft and chamber in his published account in 1738. Five years before Shaw's book was published, in 1733, Charles Thompson visited the Sphinx and mentioned the shaft and chamber

in his book of 1754. Meanwhile, in 1743, ten years after Thompson's visit but eleven years before his account was published, Richard Pococke described the shaft and chamber. They were mentioned again in 1757 by the Dane Friderik Norden. The entrance to the shaft then became inaccessible due to sand covering most of the back of the Sphinx, as Coutelle tells us in 1798. (Windblown sand covering the back of the Sphinx is clearly seen in figure 1.46.) But in the nineteenth century it was cleared first by Caviglia, whom we have already encountered. He entered and mapped the subterranean chambers, and then they were studied again by the archaeologist Auguste Mariette, whose account was published in 1855 (a translation of which may be found in appendix 1). Ludwig Borchardt mentioned the shaft and chamber in 1897 (in his pamphlet "On the Age of the Sphinx at Giza," translated here in its entirety, in appendix 2). And finally, Selim Hassan, excavator of the Sphinx, mentioned them again in his book of 1953. Incredibly, every one of these accounts has been overlooked until now. This shows that the state of scholarship in the Egyptological field has fallen to a very low level indeed—so perilously low, in fact, that it calls into question almost any assertion made today about anything in the entire field. The day of the Egyptological scholar appears to be gone. One of the problems is that professionals are too narrowly educated today, and too narrow also in their professional activities. Many of them would like to display wider interests, but they are cowed and intimidated by peer pressure into confining themselves to small areas of expertise. Anyone who dares to go against this bullying and "political correctness" run amok risks his or her career. So they keep their heads down and do not dare to challenge the Monitors of Narrowness. Thus, the public cannot obtain enlightenment, and a vacuum is created into which all sorts of "outsiders" enter. Then the Egyptologists complain because things are being written by "outsiders." But the Egyptologists themselves are largely to blame, by failing in their duties of communicating with the public themselves.

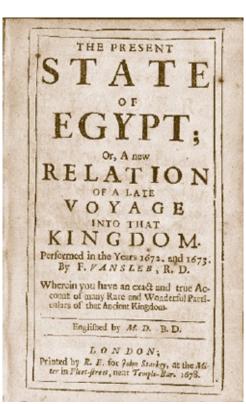

Figure 2.1. This is the title page of the English translation published in 1678 of the book by "Father Vansleb," the German traveler Johann Wansleben. Wansleben visited Egypt twice, in 1664 and again in 1672. This translation does not contain all that he wrote, so I have translated further sections from the German original. The page of this translation discussing the Sphinx is also reproduced here, as figure 2.2. Wansleben describes seeing the chamber beneath the rear portion of the Sphinx, writing that it was of the same dimensions as the Sphinx's head. (*Collection of Robert Temple*)

Anyone who has the intention of seriously discussing the Sphinx should as a first step collect all the

existing textual evidence about the Sphinx that can be found. Sensing that it was my duty to find out what others had said about the Sphinx before I myself had the temerity to say anything at any length, I spent many months gathering all the reports of the Sphinx I could find. And I did this first, before I started writing what I myself might think. Many of the reports I found were in foreign languages, of course, so I translated or had translated every one that was not in English. My wife, Olivia, translated those that were in French, I translated the ones that were in German (and some other German material was later translated with my colleague Eleonore Reed), and a friend translated one from the Dutch. The two in Latin were already published in English, and the Arabic ones that I was able to find were already published either in French or English translations. Doubtless I have missed some other Arabic texts, but I cannot read that language, and alas, this is one of my many failings and weaknesses. The Arabs are underrepresented, but with all their oil money, they ought to do more to make their own literature available to us infidels.

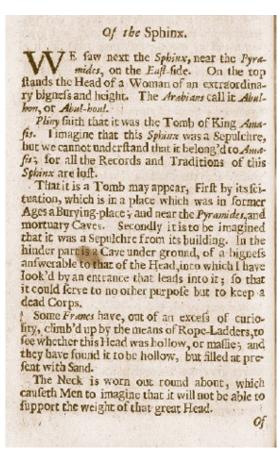

Figure 2.2. The page from the book by "Vansleb" (Wansleben) describing the Sphinx and the chamber beneath. (Collection of Robert Temple)

The result of these labors of mine and Olivia's was nearly sixty typed pages of descriptions of the Sphinx from the earliest times (Roman) until 1837 (see part 2 of this book), when we stopped trying to be comprehensive. These are very intriguing descriptions, and they reveal much.

Part 2 is intended as a standard reference source for everyone interested in the Sphinx in the future. There will be no need for anyone researching the Sphinx to go to libraries and dig it all out and translate it, as we have already done that for them. Also, anyone reading this book who wants to check a reference has only to turn a few pages, rather than plan a visit to a major international library.

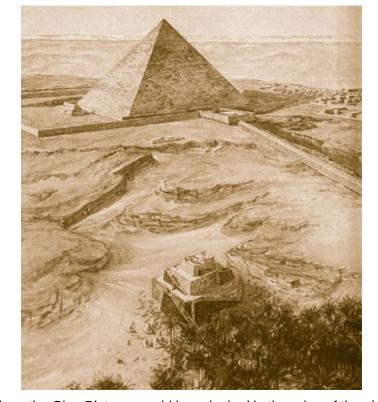

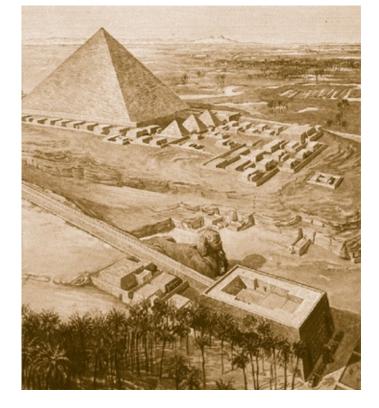

Figure 2.3. A reconstruction of how the Giza Plateau would have looked in the reign of the pharaoh Chephren (Khafre) of the Fourth Dynasty, as envisaged in 1912. This drawing was published as the frontispiece to Das Grabdenkmal des Königs Chephren (The Funerary Monument of King Chephren), by Uvo Hölscher, Leipzig, 1912. The reconstruction was done by Hölscher and the artwork by Hölscher and A. Bollacher. The rectangular structure beside the Sphinx is the building that we now call the Valley Temple. It is linked by a covered causeway to the Pyramid of Chephren. The Great Pyramid is in the background, surrounded by many tombs of officials. What is missing from this reconstruction is the Sphinx Temple, situated directly in front of the Sphinx, which at this date was still entirely unknown because it was buried in a mound of sand. Instead, the area in front of the Sphinx in this view is shown simply as a flat expanse of sand. The Sphinx Pit, which had not yet been excavated, was not understood at this time either. Instead, in this view, the area to the left of the Sphinx is not bounded, but is open. Consequently, the vicinity of the Sphinx as shown here is falsely depicted. We now know that there was also a causeway in front of the Great Pyramid, but it is not depicted here at all. One interesting feature of this view is the distant hill on the horizon, with two pyramids sticking up on top of it. This is the site called Abu Ruash. In fact, there is no conclusive evidence that any pyramid was ever fully constructed on that hill, much less two, though there is a gigantic hole in the ground on that hill that looks like the descending passage and chamber of what might have become a huge pyramid, if it had been finished. (Or it may have had another purpose; no one really knows.) It was at Abu Ruash that the small limestone female sphinx was found (see figures 4.3 to 4.6). It is a pity that more reconstruction drawings like this are not produced today, because even when they are wildly inaccurate, as this one is, they do give a vivid impression of the magnitude and grandeur of the Giza concept and help us visualize something of the general appearance of what ancient Egyptian monuments would have looked like when they were not ruins. As for the depiction of the Sphinx here, it is entirely incorrect and out of proportion. The body has been given a muscular, leonine form, and a gigantic head has been placed on the body, which the real Sphinx does not possess. When we look at the details of this picture, almost everything is wrong. But when we glimpse the totality, it still conveys an impression to us of the greatness of the Old Kingdom and its monuments.

In the next chapter, I discuss one incredible piece of information recorded about the Sphinx in 1482, which I point out must have survived as folklore for approximately seventy-five generations—clearly a world record! There is no other explanation for that particular instance. But it does not relate to a chamber under the Sphinx, so it is left until later.

It is always simplest, and often best, to survey a series of descriptions chronologically as they occur. So this is what we shall do. The earliest apparent description of a shaft and chamber beneath the Sphinx that I found came from the seventeenth-century German traveler Johann Wansleben, so we will start with him. He actually visited Egypt twice, in 1664 and again in 1672. He wrote accounts of both journeys, but only the account of the second journey was translated and published in English, in 1678 under the title *The Present State of Egypt*. Both of Wansleben's accounts were published together in German in 1794, and I have made my own translations from the two accounts in that edition. First let us see what Wansleben wrote about the Sphinx in 1664, which does not mention any shaft or chamber:

## Chapter 2. Concerning Abul-Haula, or the Sphinx

Near to the first pyramid, and below it, stands in the ground Abulhoula, or the Sphinx, as the French call it. It is an uncovered head and neck skillfully put together from stone; it is not hollow, but solid, and is 26 feet [Fuss] tall, as the Dutch Consul Johann Thyls has measured it. Nothing more protrudes above the earth; what is under the sand, I cannot say. The nose of the Sphinx has been chopped off and the moors tell a polite fiction about how that happened, which for the sake of brevity I omit.<sup>3</sup>

Now we shall see what Wansleben wrote about the Sphinx in 1672, when he studied it more closely, first taken from the English translation published in 1678, and then my own translation of the German original. Here is the version of the translation that was published in 1678:

We saw next the Sphinx, near the Pyramids, on the East-side. On the top stands the Head of a Woman of an extraordinary bigness and height. The Arabians call it Abul-hou, or Abul-houl.

Pliny saith that it was the Tomb of King Amasis. I imagine that this Sphinx was a Sepulchre, but we cannot understand that it belong'd to Amasis; for all the Records and Traditions of this Sphinx are

lost.

That it is a Tomb may appear [old-fashioned way of saying "may be seen from the facts that"], First by its situation, which is in a place which was in former Ages a Burying-place; and near the Pyramides, and mortuary Caves. Secondly, it is to be imagined that it was a Sepulchre from its building [oldfashioned way of saying "its form"]. In the higher part [evidently the seventeenth-century publisher's error for "hinder part," the original German word being *hinterwärts*, which means "hinder part" or "rear part"] is a Cave under ground, of a bigness answerable to [old-fashioned way of saying "equivalent to"] that of the Head, into which I have look'd by an entrance that leads into it; so that it could serve no other purpose but to keep a dead Corps.

Some Francs [Frenchmen] have, out of an excess of curiosity, climb'd up by means of Rope-Ladders, to see whether this Head was hollow, or massie [solid]; and they have found it to be hollow, but filled at present with Sand.

The Neck is worn out round about, which causeth Men to imagine that it will not be able to support the weight of that great Head.<sup>4</sup>

It is important to note that the account of what the Frenchmen found on top of the head is recorded as hearsay, and is not Wansleben's eyewitness account. And we know that although there is a hole in the head, it is only a narrow drilled one that goes down a few feet, and was at that time filled with sand, so people thought it led to more than it did.

The original German text has one additional sentence that was not translated in the English edition, which merely says: "One can find the measurements of the Sphinx in Thévenot." This is a reference to Jean de Thévenot, who visited Egypt in 1655 and published a lengthy account of his travels in French in 1664–84, which was translated and published in English in 1687.<sup>5</sup>

I have translated the portion of Wansleben's second account more accurately, and here is the section that relates to the shaft and chamber: "It has a cavity under the ground there rearwards [hinterwärts], the width of which measures the same as the height of the head [which is 26 feet according to his 1664 account], into which I looked from an opening into it, and which can have served no other purpose than to have the corpse of a dead person put into it."

If it were not for the existence of the many subsequent accounts, we might be inclined to assume that this description is somehow a confused account of looking down into the hollow at the bottom of the rump tunnel. But we must remember that the base of the back of the Sphinx was covered by sand at this time. So the reference must unquestionably be to something that Wansleben saw by descending into the shaft at the beginning of the Sphinx's hips. And although, as we have seen in the first chapter, he might have been able to crawl around to the rump tunnel from there, the hollow at the end of the rump tunnel is not of the size that Wansleben describes, nor is it large enough to have contained a corpse. Wansleben thus seems to have seen a different cavity beneath the Sphinx, which was considerably larger. And to confirm this, we must consider the subsequent accounts, which make the matter much clearer.

To understand how Wansleben was able to have such access to the Sphinx in 1672, it is useful to note what was stated about the sand level by a traveler who visited the Sphinx in 1614, Pietro della Valle. His testimony makes clear that in the seventeenth century, the sand level was not quite as high as we might have imagined. Although Wansleben says that only the head and neck protruded from the sand, more of the neck was probably visible, and hence more of the back, than we are used to seeing in the nineteenth-century photos of the head and neck protruding from the sand. According to Pietro della Valle, in 1614:

"The country round there is very level and sandy, and the sand has increased in such a way that the Sphinx is buried there almost up to its shoulders." We must thus probably understand Wansleben's "head and neck" as meaning that the tops of the shoulders were also visible, and that with such a sand level, more of the back was exposed than was the case in Victorian times.

Six years after the second visit to the Sphinx by Wansleben, and in the same year that Wansleben's account was published in English (1678), the Englishman Ellis Veryard, a medical doctor from Colyton in Devon, doubtless with a freshly printed copy of the Wansleben book in his eager hand, visited the Sphinx and saw the shaft and the chamber. But he did not actually publish his account until long afterward, in 1701. So what happened next in the chain of publications was something quite different. A bizarre book appeared in Dutch that purported to be by an Englishman named Edward Melton, who was said to have visited Egypt and the Sphinx in 1661, before Wansleben's first visit. For a long time I was puzzled by this book, in which the author is described specifically as "an English nobleman." I made extensive efforts to trace an Edward Melton, and even consulted a seventeenth-century manuscript pedigree of the Melton family in the British Library (MS. Egerton 3402, f. 119 verso), but there was no Edward mentioned anywhere in it.

The book by "Melton" was first published at Amsterdam in 1681 and was so successful that it was reprinted in 1702.<sup>8</sup> Strangely, for a book so successful in Dutch and supposedly written in English by an "English nobleman," no English edition ever appeared. After I had obtained a translation of the relevant passage from Dutch and could compare it to Wansleben's text, I realized that it was largely a paraphrase of Wansleben and Thévenot combined. It could not have been an original account by "Melton" as was claimed, because the very phrases themselves were copied from others. And when there were changes, they were apparently fraudulent, such as "Melton" claiming that he had climbed up on top of the Sphinx's head himself, in the way that Wansleben had said the Frenchmen had done. "Melton" refers to no shaft, but says the Sphinx sits above a basement which "has an entrance. This basement was without doubt used to bury the bodies of dead men.".<sup>9</sup>

There seems little point in giving the full text from "Melton," as I became convinced that he never existed, and that the work and the author are equally spurious. Strangely, the existence of Melton has been uncritically accepted by several well-known Egyptologists over the years, not because they were interested in what he had to say about the Sphinx (there being no evidence that they ever read that bit), but because they were searching for early accounts of the two stone pyramids at Dashur, one of which is called the Red Pyramid and the other the Bent Pyramid because it changes the angle of its exterior slope in a very dramatic way. Those authors included Howard Vyse, Ahmed Fakhry, and Dietrich Wildung. However, a survey of the situation was published as an article by Kathleen M. Pickavance in *The Journal* of Egyptian Archaeology in 1981.<sup>10</sup> In her article, Pickavance struggles with the problem of Melton. She adds the information, possibly spurious, that he was "Born c. 1635 the second son of Sir John Melton, Kt. of London," and he studied at Oxford. I doubt this. I own my own copy of Athenae Oxoniensis, which surveys all Oxford men who became authors before 1721, and the only Melton who appears in the entire giant folio volume is a Wiliam de Melton of Yorkshire who died in 1528. 11 Pickavcance says of Melton's account of entering the Bent Pyramid at Dashur: "It is hardly to be believed. . . . The greatest obstacle to the belief that Melton entered the Bent Pyramid by the western entry rests in Perring's description of the state of the western passage as he had found it in 1837: 'The greater part of it was closed up with large blocks.' . . . We are then faced with the inconceivable possibility that the western passage was more or less open in 1661, and subsequently closed up again, with all the flush-fitting blocks in place, when Perring saw them in 1837. In fact, it is the archaeologists' findings which must surely prove that the belief that travelers entered a chamber in the Bent Pyramid from the west is untenable, and that any account which even suggests such a possibility is either misleading, false, or a misinterpretation." I would go so far as to say that the real reason why 'Melton' did not actually enter the Bent Pyramid as he claimed was that he did not really exist. The book attributed to him appears to have been a publishing hoax carried out for commercial motives. Some Dutchman must have pocketed a lot of money and laughed at the fools who were taken in by his tricks.

The next thing that happened in the succession of publications is that Ellis Veryard's account of his journey to Egypt and other countries was finally published in 1701, twenty-three years after it had taken place. Here is what he had to say about the Sphinx:

About half a Mile from the Pyramids we saw an ancient Colossus representing the Sphinx, with a Woman's face, and the Body of a Beast. This Statue was in so great Veneration amongst the Egyptians heretofore, that they gave it the first place amongst their Gods, and received all their Oracles from it, which the Devil utter'd thro' the Mouth of this artificial monster. The Body is buried in the Sand, and only the Head and Breast remain above Ground; so that we may judge of the vast bulk of the whole by the Face, which is twenty four foot long. [Wansleben had said 26 feet, so Veryard must have taken his own measurements.] Pliny says it was the Tomb of King Amasis; but I am apt to think it was an Ornament placed on his Sepulchre; for behind it we found a Subterranean Vault cut out in the firm Rock, which in all likelihood was the Tomb. <sup>13</sup>

The phrasing is brief and vague, but as Veryard specifically says that he believed the Sphinx sat *on top of* the sepulchre, and then proceeds to say that the same sepulchre was "behind it," we must presume that he means behind the protruding head rather than behind the entire Sphinx. If he had meant to refer to a burial in the rocks a considerable distance behind the entire Sphinx, in the cliffs of Giza, this would have been in contradiction to his affirmation that the sepulchre was *beneath* the Sphinx. He must therefore be referring to the same chamber mentioned by Wansleben, which was *hinterwärts*, or to the rear of, but not behind and away from, the Sphinx. And once again we have specific testimony that the sand was too high for this to be the hollow at the base of the rump tunnel, as the opening at the base of the Sphinx was inaccessible.

The next publication mentioning the chamber beneath the Sphinx was fourteen years later, in 1715, when the English translation of Pancirollo appeared, the anonymous translator of which added the information, as I have described in the previous chapter. However, the unattributed description by the anonymous translator was something I eventually tracked down when I discovered Wansleben's book, since the passage is taken directly from the 1678 English edition of Wansleben. And so that mystery, which had plagued me for many months, was solved. It was, after all, the Pancirollo book that I first encountered, and it was only by discovering the passage in it (which at first I assumed was translated from Pancirollo's original Latin work, until, having gone through all of its successive editions from 1599, I realized it was really an interpolation by the English translator) that I realized I had to find its source, which led to my discovering all the other references to the "secret chamber," and writing this chapter.

Here, then, is what the anonymous translator of Pancirollo inserted into Pancirollo's book in English in 1715 and which was reprinted in 1727, repeated so that the succession of relevant quotations may be complete:

I imagine this Sphinx to be a Sepulchre, but we cannot understand how it belong'd to Amasis [the Greek name of a pharaoh whom he mentioned earlier, said by Pancirollo to have constructed the

Sphinx], for all the Records and Traditions of this Sphinx are lost. That it is a Tomb, may appear, 1. By its Situation, which is in a Place, which was in former Ages a Burying-Place, and near the Pyramids and mortuary Caves. 2. It is to be imagin'd that it was a Sepulchre from its building. In the hinder Part is a Cave under Ground, of a Bigness answerable to [an eighteenth-century expression meaning "comparable to"] that of the Head, into which the curious have look'd, by an Entrance that leads into it; so that it could serve no other Purpose but to keep a dead Corps [corpse] in, as Travellers inform us. 15

Notice that the translator specifically says this information comes from "travellers." So it is not a plagiarism in the style of "Melton." The question that I was confronted with for so long was: Who were the travelers? It is now clear that the travelers were Wansleben and Veryard. The text is more or less lifted directly from the English translation of Wansleben's book and adds nothing new. Mystery solved. But imagine how difficult it was to solve it, without any clues whatsoever and only a cutoff date of 1715 to go by. However, such are the perils of scholarship, and sometimes one succeeds, as I fortunately did here.

The next step along the road of published accounts about the Sphinx chamber came in 1721, when the famous English traveler Thomas Shaw visited Egypt. His account of his travels was published in 1738. It is very well known, and ignorance of his comments on the shaft and chamber among Egyptologists is less excusable than it is for the preceding and highly obscure works that I have already cited.

Here, with Shaw, we finally get the specific and detailed information that we so greatly desire, frustrated as we have been with the vague and dreamy accounts of the previous visitors. For the satisfaction of readers, I shall give all of the comments on the Sphinx made by Shaw, commencing with some preliminary ones:

The catacombs of Sakara, the Sphinx, and the Chambers, that are cut out of the natural rock, on the east and west side of these pyramids, do all of them discover [i.e., display] the specific mark and characteristics of the pyramidal stones, and, as far as I could perceive, were not at all to be distinguished from them. The pyramidal stones, therefore, were, in all probability, taken from this neighbourhood; nay, perhaps they were those very stones, that had been dug away, to give the Sphinx, and the chambers I have mentioned, their proper views and elevations. <sup>17</sup>

A few pages later, Shaw returns to the Sphinx itself:

## Of The Sphinx

Besides what has been already said of the Sphinx, we are to observe, that in July 1721, the sands were so far raised and accumulated about it, that we could only discover the back of it; upon which, over the rump, there was a square hole, about four feet long, and two broad, so closely filled with sand, that we could not lay it open enough to observe, whether it had been originally contrived for the admission of fresh air; or, like the well in the great pyramid, was intended for a stair-case. Upon the head of it there is another hole, of a round figure; which, I was told, for we could not get up to it, is five or six feet deep, and wide enough to receive a well-grown person. The stone, which this part of the head consists of, seems, from the colour, to be adventitious, and different from the rest of the figure, which is all of the same stone, and hewn out of the natural rock. [This is a very sharp observation, for we now know that the head was carved from a stratum of stronger limestone than the body and is indeed harder and "different," quite apart from the fact that it seems to have been cut

down and recarved by a later pharaoh in his own image.] It must be left to future travellers to find out, whether these holes served only to transmit a succession of fresh air into the body of the sphinx, or whether they might not have had likewise a communication with the great pyramid, either by the well, or by the cavity or nich [niche] in the wall of the lower chamber [the Subterranean Chamber], that lies upon a level with it. Nay, it may some time appear, that there are chambers also in the two other pyramids [we now know this to be true]; and not only so, but that the eminence likewise, upon which they are both erected, is cut out into cryptae [crypts], narrow passages, and labyrinths, which may, all of them, communicate with the chambers of the priests, the artful contrivers of these adyta [adyta is plural of adytum, which means a restricted area at the back of a temple, reserved for the priests]; where their initiatory, as well as other mysterious rites and ceremonies, were to be carried on with the greater awe and solemnity. 18

Here we have the first clear and detailed description of the entrance to the vertical shaft, together with careful measurements of its dimensions. Wansleben and Veryard had not bothered with such things. But in the forty-three years that had elapsed since the visit of Veryard, the shaft had become filled with sand again, so Shaw was unable to descend into the chamber below. The location of this carefully constructed entrance to a shaft confirms the information we have had from Wansleben and Veryard that it was at the rear of the Sphinx's body, associated with the haunches of the creature.

Anyone familiar with the way things have worked at Giza over the centuries, in terms of local families and their habit of earning their living from visiting foreigners' baksheesh, can well imagine what had transpired. Reading through all the travelers' reports over many centuries as I have done and as the reader may now do (since they are all collected and printed in this book), one finds a remarkable continuity of behavior on the part of the locals and their insatiable demands for baksheesh, as well as their devices for obtaining more. For instance, it is obvious that the local guides had measuring rods ready at hand for all the visitors, since they all make their own measurements of the Sphinx's head, and they cannot possibly all have come with their own rods! But trying to find a new angle to make more money in the middle of the seventeenth century, some enterprising man from the adjoining village now called Nazlett (but in Greek times known as Busiris, which is not to be confused with the other city called Busiris, which is far away in the Nile Delta; the old Egyptian name for Nazlett was Djedu, which means "ghosts") must have decided he could get more baksheesh if he cleared the sand from the vertical shaft in the haunches of the Sphinx. This must have caused him and his family and friends a great deal of trouble. But they were well rewarded in that they were able to expose a subterranean chamber, though from the surviving accounts, it appears that their clearance was not complete, since Wansleben and Veryard appear only to have peered into the chamber from the shaft. There is no evidence that they really were able to clamber into the chamber and inspect it fully. Probably the locals simply could not cope with clearing the chamber of all of its sand, and they thought that offering a glimpse to visitors prepared to thrust their heads inside would suffice. The encroaching sands kept pouring down the shaft, the man who initiated the clearance then presumably died during the forty-three years that intervened before Shaw's visit, and the locals were too lazy to keep the shaft open. However, the entrance remained exposed, and Shaw was able to measure it. It is interesting that Shaw found the sand that filled the shaft so compacted or intractable that he was unable to clear enough to examine the shaft as he wished to do.

The next traveler to describe the entrance to the shaft took much more trouble than Shaw did over the matter. He was Charles Thompson, who visited Egypt in 1733 and published the account of his travels in 1754. Since Thompson's visit to the Sphinx took place five years before Shaw's book was published, Thompson's investigation of the shaft entrance was independent, and was not motivated by reading Shaw.

In volume 2 of his lengthy work, Thompson records this interesting information:

Before I leave this Place [Giza], I must take some Notice of a Colossus, at least the Head of one, which stands about a Quarter of a Mile to the East of the second Pyramid. It is usually call'd a Sphinx, which is a fabulous Monster, having the Head and Breasts of a Woman, the Wings of a Bird, the Claws of a Lion, and the Body like a Dog. This figure, among the Egyptians, was a symbolical Representation of the rising of the Nile in the months of July and August, when the Sun passes through the Signs Leo and Virgo. They likewise made use of it in their Hieroglyphicks to represent a Harlot, intimating the Danger of being captivated by the Charms of a faithless Woman, whom the fond Lover in the End finds as cruel and rapacious as a Lion. Of this Sphinx however, near the Pyramids, there is little to be discern'd but from the Shoulders upwards, being a monstrous Bust of a Woman, all cut out of the solid Rock, and never separated from it; except the upper Part of the Head, which seems to be adventitious [added on]. It is almost thirty Feet high, fifteen feet from the Ear to the Chin, and above thirty feet wide at the lower Part of the Neck or Beginning of the Breast. The sand is so accumulated about it, that one can but just discover the Top of the Back, in which there is a Hole about five Feet long, seventy-five [feet] from the hinder Part of the Neck, and thirty from the Tail. We could not get up to the Top of the Head, but those who have done it report, that there is a round Hole, by which a fullgrown Person may descend into it, from whence it is supposed the artful Priests deliver'd their Oracles. Pliny makes mention of this Sphinx, and tells us that it was thought to be the Sepulchre of King Amasis. The Rock is dug away all round the Sphinx to a considerable Distance, and the Stone was undoubtedly employ'd in building the Pyramids, with which some Moderns have supposed it has a subterraneous Communication.<sup>20</sup>

Like all the visitors mentioned until now, Thompson persists in the view that the head of the Sphinx is the head of a woman. This was obviously stressed by all the guides and is a continuation of the long and persistent tradition that the Sphinx represented the goddess Isis, although her name had long been forgotten by this time, of course. (The sacred *nemes* headdress of the pharaoh, seen on the Sphinx, was presumably interpreted as a woman's head scarf or bonnet of some kind, leading people to believe that the face was that of a woman, as no man would look like that. After the end of the Ptolemaic Period, native Egyptian traditions of the pharaoh were forgotten, and the existence of such a pharaonic headdress would no longer have been remembered.)

Thompson's attention was also drawn to the "hole in the top of the back," doubtless by the same guides whose fathers or grandfathers had once cleared the shaft of sand before it filled up again. By 1733, the sand had risen so much higher that Thompson only says he could "just discover" the hole. If we had had any doubts until now of the hole possibly being the one at the rear base, these are now wholly dispelled. This hole is in the top of the back. And just to be more specific, Thompson conveniently tells us precisely where in the top of the back it was, for he has the good sense to measure the distance of the hole from the head! It is 75 feet from the back of the head, and 30 feet from the tail. In other words, it is at the point where the hips commence, and precisely where the huge crack is shown in figure 1.31 to 1.34, which Baraize completely filled with modern cement.

Thompson must have made greater efforts than Shaw did to clear the sand away from this hole, because whereas Shaw described it as 4 feet long, Thompson was evidently able to clear enough sand away to reveal a greater length of the hole, and says it is about 5 feet long. Whether it was 4 feet or 5 feet, it was a pretty large and conspicuous shaft entrance, and its complete destruction in 1926 can only be called criminal damage.

We do not have to wait long for the next visitor to see the shaft entrance. The famous Irish bishop Richard Pococke turned up at the Sphinx only a few years later, in 1739, and published the account of his travels in two volumes over the period 1743–45. Pococke was successively bishop of Ossory and of Meath in Ireland. Not only did I consult Pococke's published book, but I also consulted the twenty-one volumes of his unpublished manuscript travel diaries that are preserved in the British Library. The manuscript of the published material is significantly not included among the original travel diaries, which indicates that the original copies of that material went to the publisher and were not returned to Pococke again afterward, which was apparently standard publishing practice. However, some further remarks about the Sphinx were made by Pococke in a letter to his mother, which I give here first: "I went to the Sphynx the head much worn by time, especially in the neck, one just sees the top of the back & either a tail or a thigh in a sitting posture;—the whole by the nicest examination I could make seems to be cut out of the rock;—went into some catacombs & round the second Pyramid. We dined together & returned."<sup>23</sup>

The main description of the Sphinx mentions the rear shaft, which he does not bother to mention in the letter, and considering how well Pococke's book is known, it is amazing to me that no Egyptologist has ever mentioned this before:

Directly in front of the second pyramid, about a quarter of a mile to the east of it, is the famous sphinx H [a reference to his engraving, Figure XVI, where the Sphinx is marked H on a plan of the Giza Plateau] about half a quarter of a mile from the water when the Nile overflows, being on much lower ground than the pyramids. Here seems to have been the grand way up to these magnificent structures. . . . The rock seems to have been dug away all round the sphinx for a great way, and the stone was doubtless employ'd in building the pyramids, the sphinx being cut out of the solid rock; for what has been taken by some to be the joining of the stone, is only veins in the rock. This extraordinary monument is said to have been the sepulchre of Amasis, tho' I think it is mention'd by none of the antient authors, except Pliny [36.12]. [Pococke's footnote here states: "My account makes the sphinx one hundred and thirty feet long, that is about seventeen feet more than Pliny. He says it was sixtythree feet high, probably taking in a plinth that might be cut out under it; so that about thirty-six feet must be buried in the sand."] I found by the quadrant that it is about twenty-seven feet high, the neck and head only being above ground; the lower part of the neck, or the beginning of the breast, is thirtythree feet wide, and it is twenty feet from the fore part of the neck to the back, and thence to the hole in the back it is seventy-five feet, the hole being five feet long, from which to the tail, if I mistake not, it is thirty feet; which something exceeds Pliny's account, who says that it is a hundred and thirteen feet long. The sand is risen up in such a manner that the top of the back only is to be seen; some persons have lately got to the top of the head, where they found a hole, which probably served for the arts of the priests in uttering oracles; as that in the back might be to descend to the apartments beneath.<sup>24</sup>

Here we see that the entrance to the rear shaft, "the hole in the back," is described once again as 5 feet long. I suspect that Pococke took the measurements of the distance from the head and tail directly from Thompson, as his letter to his mother does not indicate that he spent sufficient time at the Sphinx to have taken personally all the measurements that he reports. He adds that the rear shaft was possibly intended "to descend to the apartments beneath," but these were as invis ible in his day as they were in Thompson's.

Following Pococke, the Danish traveler Friderik Ludvig Norden, known in English as Frederick Lewis Norden, visited Egypt. He was a captain in the Danish navy. He wrote a book about his travels,

which was published in French in Copenhagen in 1755. The English translation of his travels was published in 1757. (A German translation followed in 1779.) Norden does not give much description of the Sphinx, merely saying that its "enormous size attracts your admiration, and at the same time you conceive a sort of indignation at those, who have had the brutality to disfigure strangely its nose." The reason I mention Norden is that he quotes the passage from Pococke that mentions the shaft opening, thus giving wider attention to the subject. This wider attention was unproductive, however, as no one until now seems ever to have taken any notice of it whatever.

There seems to have been a kind of Curse of the Sphinx that made everyone blind, so that no matter how much was published about it, no one read it. Perhaps this book will break the spell at last.

That was the end of the early references to the shaft and chamber. Within decades, the sand had risen to such a height that even the entrance to the shaft had become invisible. Coutelle describes the Sphinx as it was during his visit in 1798 when he arrived with the Napoleonic expedition:

## 8. The Sphinx

It is in one of the faults of the Libyan hills, in the area which rises towards the west across the plain, that the sphinx has been cut; its height is about 13 metres [40 feet] above the actual ground, it remains like a witness and like a mass of stone raised up which has been superficially made to decorate this part of the hill. The rump, scarcely perceptible, seems only traced in the earth with a length of almost 22 metres; and the side which we wanted to discover in clearing away the sand which the winds had accumulated up to the level of the hill, presented no regular shape to us to a depth of approximately 9 or 10 metres [30 feet]: as to the hole which had been noticed on the [top of the] head, it is not deeper than 2 metres 924 mm [9 feet], of a conical and irregular shape.<sup>27</sup>

From this we learn that the Sphinx was hopelessly obscured by sand at this time. In fact, such was the deluge of sand over the monument that the French actually undertook an initial clearance in 1798, and although Coutelle mentions the clearing of one side to a depth of 30 feet, they later concentrated on exposing the rear (see figure 2.10 for a drawing by Robert Hay of the cleared rump) so that they might arrive at a reliable measurement of the length of the Sphinx. This is described by Coutelle's contemporary Joseph Grobert:

Now we must leave the place far from the pyramids and go down towards the east. One follows the plateau; one passes in front of the meridional [north] face of [the Pyramid of] Chephren, and one moves off as far as one can from it to the right. One goes down quite a gentle slope to find the Sphinx, almost entirely covered by sand, and of which the projecting head is concealed from the eye by the unevenness of the ground.

Figure 2.4. The Napoleonic Expedition

[Count Constantin-François de] Volney, the only author worth quoting when you want to recount a sound idea about this region, has rightly observed that the completely Ethiopian profile of the Sphinx bears witness, in an authentic way, that that nation has given the Egyptians its laws, its morals, and its religion. These last are no more than a colony descended from Sennahar and some vast regions which encompass Nubia; they have deteriorated by mixing with the Arabs. The foreigners who can stand the disgusting sight of the Hokheila [evidently a slave market] where Negroes are sold, will not find much there to resemble the profile of the Sphinx.

This monstrous statue, truly colossal, has been sculpted from a protruding piece of rock on which it sits. It is from a single piece. The quality of the stone perfectly resembles the rock itself despite being painted yellow, and the colour has been conserved up until our day in the places where it has not been damaged. Paintings found in Upper Egypt attest the talent of the Egyptians in composing colours and the influence of the dryness of the climate in preserving them.

The Sphinx is actually very dilapidated, much more than it was in 1738 when [Friderik] Norden drew it. I uncovered enough of its back to measure it. But there should be a very considerable excavation to uncover it entirely [this did not finally happen until 1926]. If one climbs onto the head, one sees a hole which is fifteen inches in diameter at its widest point, and about nine feet in depth. The direction is oblique. One sees that the depth has been diminished by stones which have been thrown down into it. It would be difficult to determine the use of this cavity, unless one presumes some underground passage which this passage leads to, and that the priests hidden in this place delivered their oracles from it. The Sphinx was definitely an idol, and the tutelary divinity of this cemetery. The placement of the surrounding sand makes one suspect that the plain, which is at the foot of the rock to the south, and which is more elevated than the usual flood level of the river, is equally strewn with tombs.—A little to the south-west is a tomb where a Turkish hermit lives, a chapel around which several trees have been planted.<sup>28</sup>

Two subsequent English travelers testified to the extent of the French clear ance. The first was Edward Clarke, whose description is given in full on page 493, where he comments upon the "wretched structure of brick-work, and small pieces of stone."<sup>29</sup>

Clarke was obviously far more impressed by the French clearance than was the famous William Hamilton, who somewhat earlier had written:

A large and strong built causeway [the causeway of Chephren] has been carried from the entrances of

each of these enclosures [the funerary temples in front of the Pyramids of Mycerinus and Chephren] to the celebrated sphinx, whose enigmatical meaning still continues to puzzle the antiquaries of Europe, and who has proved during a long lapse of ages the faithful depository of the mysteries which envelop every object round her. The French excavated the body of the lion; which they found uninjured: but the sands of the Desert very soon rendered their labour vain, and the last time I saw the sphinx, the head and neck alone were visible. These have been evidently painted all over, and many characters are to be traced upon the head-dress; but we could not ascertain whether they were the sacred or popular letters of Egypt [i.e., hieroglyphics or hieratic writing]; some indeed bore a resemblance to the Arabic. It is still a point of dispute among the learned, whether this combination of the human and the lion's form is typical of the rising of the Nile, the summer solstice, or the wisdom and power of the deity. Such a personification of human intelligence and brutal force might be the original of the Greek Minerva; and agreeably to this supposition, the sphinx is a very common ornament of this goddess on her statues and on her medals. 30

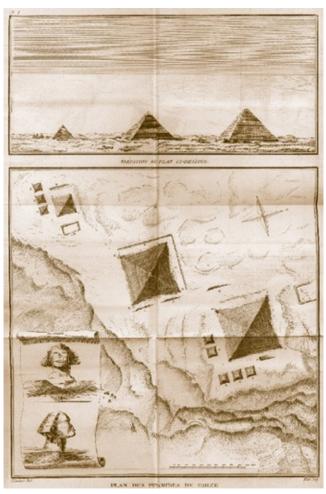

Figure 2.5. This is plate 1, a folding plate, from J. [Jacques-François-Louis] Grobert, *Description des Pyramides de Ghizé*, Paris, "An. IX" (i.e., 1801). The top view shows the three Giza pyramids, the Great Pyramid at right, the Pyramid of Chephren in the center, and the Pyramid of Mycerinus at the left. Below the left corner of the Pyramid of Chephren, the head and back of the Sphinx may be seen sticking out of the sand. This is a clear indication of the extent of the clearance of the Sphinx made by the Napoleonic Expedition, and is confirmed by the plan seen in the view below. The French obviously cleared the entire back to arrive at a reliable measurement of the length of the sculpture. On the plan below, the Sphinx is marked "T" (which can barely be seen in front of the Sphinx's head near the bottom of the plan) and sits alone in the sand, with no trace shown of either the Valley Temple or the Sphinx Temple. Behind and to the left of the Sphinx, marked "S" on the plan, are three old sycamore trees (still surviving in the nineteenth-century photo in figure 3.9) and a building that had vanished by Victorian times, which we know from written sources was the residence of a Muslim hermit. The plan shows cultivated fields at bottom right, reaching right up to the cliff edge, and these would have covered the site of the Cheops Valley Temple, which has never been excavated (but some carved blocks from which survive as reused blocks at the site of Lisht, farther south). Today, this unexcavated temple lies beneath a private house in Nazlet el-Samman. The plan also shows the contours very well, which indicate how the Nile's inundation waters (which

even in Victorian times still covered those fields and went up to the cliff base) were able to approach the feet of the Sphinx, which had no cliff barrier like that barring the way to the Great Pyramid. It is interesting to see that in 1798/9, when this plan would have been drawn, one boat pit was known in front of the Great Pyramid. The Chephren Funerary Temple and Causeway were completely covered in sand. Not a single mastaba can be seen. The empty square shown behind the Sphinx, more or less directly in the path of the Chephren Causeway, seems too far back to be Campbell's Tomb, and may be a ruined superstructure that once stood on top of the causeway above the entrance to the so-called Osiris Shaft, which lies beneath the causeway. (My account of the Osiris Shaft is published in *Egyptian Dawn*.) (*Collection of Robert Temple*)

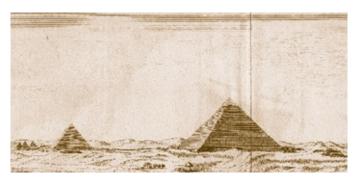

Figure 2.6. An engraving of the Pyramid of Chephren, center, and the Sphinx, bottom center of the picture, as seen in the seventeenth century. The small building to the left of the Sphinx beside some trees was a hermit's cell, which had vanished by the nineteenth century but is mentioned in the early travelers' accounts. At left in the engraving is the Pyramid of Mycerinus. This is the top portion of plate 1 from J. Grobert, *Description des pyramides de Ghize*, Paris, 1801 ("An. IX" of the Republic). (*Collection of Robert Temple*)

The only possible explanation for the conflicting statements of Hamilton and Clarke would seem to be that after Hamilton left in 1801, the French must have undertaken a second clearance before Clarke arrived. An unpublished manuscript by James Burton in the British Library reveals more interesting details about the various Sphinx clearance operations. Burton visited Giza in 1822, and his manuscripts show that he intended to publish an extensive account of his Egyptian travels, but he never did so. Perhaps because he was frustrated in this aim for some reason, all his papers were left to the British Library, where they have been carefully preserved but apparently rarely consulted. In fact, they are a priceless scholarly resource, full of wonderful information and illustrations. Burton was a scholar, and not just a casual visitor to Egypt. He was a serious student of the Arabic language and read a lot of Arabic histories. I have copied the following interesting remarks about the Sphinx from Burton's manuscript, but have omitted earlier ones, which include discussions of what various Arabic historians had said of it, what its Arabic name meant, a discussion of its original coloring, and quotations from Abdallatif and Denon:

The statue was mutilated by a bigoted enthusiast [old-fashioned word for a fanatic], Sheckh [Sheikh] Mohammed, about year of the Hegira—? [Burton left a blank for the date.] It was probably when the nose was thus broken that the Asp [uraeus] and head dress were removed. There is little doubt that it carried these ornaments, from the hole now remaining in the top of the head, which the natives have at some time or other enlarged, in the hopes of finding in the interior some hidden treasure. The head however is solid stone, and they soon found their labour useless. I think I remember Mr. [Henry] Salt having told me, that he found in excavating the temple between its paws, part of an asp in bronze. This will have been that placed over the forehead.

The rump was repaired with Mapara [?] stone probably by the Kornans [??]—their repairs were destroyed again by the late Defterdar in order to serve as building materials for one of his palaces.

Burton is obviously referring here to the Ottoman Turkish official called the Defterdar Bey. He acted as finance minister in Egypt and was directly appointed by the sultan in Istanbul. The Defterdar actually

ranked higher than the bey (provincial governor). The office of Defterdar was abolished in 1837. The Defterdar's aims were to squeeze as much money as possible out of the subject populations and exploit any and all local resources to the fullest possible extent. It is shocking that he carried this so far that he stripped stones off the Sphinx. It is impossible to know whether this account refers to the actual rump and its casing stones or whether it might refer to stones that had been used to try to fill up the shaft at the haunches. If the latter is the case, then by removing stones from the shaft in a rough manner, he might have caused the huge crack to open and the haunches to split off, as we see in the various photos. In other words, this "rape of the Sphinx" by the Ottoman Defterdar may have split the Sphinx at the point of the shaft.

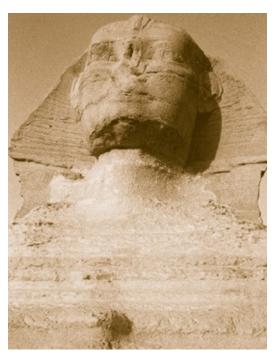

Figure 2.7. This photo shows the socket between the eyes of the Sphinx where the nose was apparently reattached after the fanatical sheikh Mohammed struck it off as being offensive to Islam in the Middle Ages. (The story about the nose being shot off by soldiers is false.) (*Photo by Robert Temple*)

Burton's account continues: "Moorad Bey [Murad Bey, died 1801; see his portrait in figure 2.8] first uncovered the Sphinx but found nothing—he did not dig deep. The French then did it, and were equally unsuccessful. [Captain J.-B.] Caviglia finally succeeded, and the accompanying notice of the work is copied from the . . . " (here the text breaks off). 31

The verso side of this manuscript leaf has Burton's copy of Henry Salt's plan of the paws and altar of the Sphinx (see figure 6.47 for Salt's plan, as it appeared in the *Quarterly Review*, which is the reference Burton intended to insert), with identifying letters and specific descriptions. No succeeding leaf has been bound into this manuscript volume, and the subsequent leaves by Burton change subject.

Figure 2.8. A portrait of Murad Bey, who died in 1801. According to a manuscript report by James Burton, who went to Egypt twenty-one years after Murad Bey's death, it was this Egyptian ruler who carried out the first modern excavations of the Sphinx, "but found nothing—he did not dig deep." Not long afterward, Egypt was invaded by the French, and they also made excavations at the Sphinx, commencing in 1798, "and were equally unsuccessful." They did, however, find evidence of an opening between the paws, which was doubtless the "altar crypt," part of which is still visible through a metal grille in the rock today (see figure 1.29), and the rest of which was sealed up in two stages 120 years apart, first by Henry Salt and then by Professor Selim Hassan. Engraving by Sonnini de Manoncourt, made in 1799, two years before Murad Bey's death. (*Collection of Robert Temple*)

We learn here what I believe is recorded nowhere else, that the Turkish provincial governor of Egypt at the end of the 1700s, Murad Bey, had actually attempted to clear the Sphinx prior to its clearance by the French in 1798. Perhaps he even tried to repair some of the damage caused by the Defterdar many decades before. Burton's comment that both Murad Bey and the French had been unsuccessful must mean that the apparent second attempt by the French was also a failure. Indeed, it was not until Émile Baraize cleared the Sphinx to the bedrock in 1926 that the Sphinx had been fully exposed since Roman times. If a search were made of the Ottoman records in Istanbul, some record of the Turkish treatment of the Sphinx would doubtless be found, both the Defterdar's despoliations and sale of stones and Murad Bey's partial excavation and restoration attempts.

I have already had occasion to point out that Caviglia, an Italian who also wrote French and spoke but did not write English, did not leave his papers in what we would consider proper order. He gave many of them to the British consul Henry Salt, who had supplied some of the funds for the clearance, and as we have seen in the previous chapter, Salt published a lengthy account of Caviglia's excavation of the Sphinx in the *Quarterly Review* in London.<sup>32</sup> A few of Caviglia's papers are preserved in the British Library, and I have looked at all of these. But as we shall see in a moment, some of his crucial papers relating to the Sphinx made their way to Florence, where they were consulted in 1833 by an English Egyptologist, none of whose notes of them appears to survive. But it was these very papers that described not only his clearance of the vertical shaft, but also his actual entry into the subterranean chamber! Unfortunately, I have no idea where in Florence these papers of Caviglia's may have been deposited, or whether indeed they are still there. My friend Stefano Greco and I undertook some preliminary searching together in Florence, and Stefano has continued this search. One unexpected find was an account in Italian by one of Caviglia's friends, Annibale Brandi, in another Italian town. The section dealing with the Sphinx has been

translated by Stefano and myself into English and is found in appendix 4. The information that it gives is discussed later on. In addition, we do have some further important information about Caviglia's activities preserved by Auguste Mariette, which is found in appendix 1, and that is discussed in a moment. And finally, as discussed later, some more material that had been "lost" since the Victorian era was recently published by the British Museum Press, having been found while moving offices. That Caviglia's work came to such an abrupt end because of his having a serious attack of sunstroke and being disabled meant that his reports were never finalized. He left Egypt suddenly, and apparently only returned to Giza to evacuate in the 1830s, more than fifteen years later.

That the Sphinx was cleared at the rear by the combined work of the French and remained so for a quarter of a century is shown in a rare rear-view drawing by the English artist Robert Hay in 1827, which I found in a manuscript in the British Library and reproduce in figure 2.8. This makes it clear that the rear portion of the Sphinx was entirely accessible for an investigation of the shaft and chamber beneath the haunches. And as we shall see, Caviglia fully cleared the shaft and the chamber in 1817 as well.

Caviglia spent ten months clearing the surrounding sand from the Sphinx, until he was incapacitated by sunstroke and had to stop, returning to his ship at Alexandria and resuming his life as a sea captain.<sup>33</sup> All this took place before Henry Salt published the account of Caviglia's work in the Quarterly Review. Caviglia's clearance and exploration of the shaft and chamber beneath the Sphinx must therefore also have taken place before Salt's publication. But why did Salt not mention it? Why, indeed, did Salt mention nothing whatever of the discoveries of tunnels and entrances relating to the Sphinx? Here we must recall the accusation made by Count de Forbin, as recounted in the first chapter, that Salt through arrogance and stupidity had blocked up some of these so that they could not be investigated further. Salt may have thought that as he was contributing to the funds that paid for the excavation, he had a right to interfere with it in this way. But what can have been his motivation? Was he just an ignorant lout? Perhaps he thought of these things as blemishes, and, having exposed the Sphinx to view, he wanted to tidy it up and plug the holes, to render its appearance more beautiful. If he thought of the Sphinx primarily as a magnificent monument that he had helped reveal to the eyes of mortals for the first time since antiquity, he might have been impatient of "imperfections" such as openings, passages, and so forth, which would have meant nothing to him, as he was not an archaeologist. It may simply be that in a pompous sort of way he was just a silly fool. Count de Forbin evidently thought so.

Left: Figure 2.9. This is Henry Salt's drawing from 1817 of the cleared space beneath the chest of the Sphinx, between its front paws. The suspended object in the center top of the drawing is the remnants of the Sphinx's beard, which had been affixed to the recarved head of the Middle Kingdom pharaoh Amenemhet II, either by himself or later during the New Kingdom, when the Sphinx was excavated by Thutmosis IV. The large upright stela in the center of the scene is the Dream Stela, Henry Salt's separate drawing of which is shown in figure 3.7. (Modern photos of this stela are shown in figures 3.8 and 4.19.) At the time of its excavation by Caviglia, the inscription on the Dream Stela was intact, as I have discovered from an account in Italian left by a friend of Caviglia, which was located by my friend Stefano Greco in an obscure Italian library, and the Sphinx portion of which, translated by us into English, is published here as appendix 4. By the time Salt was able to draw the inscription some weeks or months after its excavation (it could not yet be read, because hieroglyphics had not yet been deciphered), well over a third and nearly a half of the inscription had vanished. Since then, even more has gone, so only about half remains. The new account that Stefano and I have found explains that the inscription was peeled off by the superstitious inhabitants of the neighboring village of Nazlet el-Samman, chiefly women believing it could help them have babies if they had fragments in their homes, presumably under their beds to aid conception. This drawing is found in *Operations Carried On at the Pyramids of Gizeh in 1837* by Colonel Howard Vyse and John S. Perring, London, 1842, third appendix volume, plate opposite page 110. (*Collection of Robert Temple*)

Figure 2.10. A computer-enhanced reproduction of a drawing by Robert Hay done in 1827, showing the rear of the Sphinx free of sand and largely exposed at that date. The original drawing is exceedingly faint and is preserved in the Papers of the Robert Hay Expedition to Egypt, 1826–1838, in the British Library Manuscripts Collection (Add. Ms. 29,812, folio 67 recto). The Old Kingdom blocks are clearly drawn at the base, and thirteen rows of them are shown. The three human figures on top of the Sphinx's back are standing near the point of descent leading to the chamber beneath the Sphinx, which was entered in 1817 by Caviglia and in

But how do we know that Caviglia really entered the chamber beneath the Sphinx? This was discovered by an early English Egyptologist named Charles H. Cottrell, who seems to have published nothing of his own, but who translated a huge work by Baron Bunsen on the antiquities of Egypt, entitled *Egypt's Place in Universal History*.<sup>34</sup>

In 1855, the French archaeologist Auguste Mariette related the story, which was reported in a French periodical of that time:

In 1833 an English Egyptologist, Mr. [Charles H.] Cottrell, to whom one owes the translation of the work of Monsieur [Christian Carl Josias Freiherr von] Bunsen on Egypt [Egypt's Place in Universal History], found in Florence among the papers of Caviglia, who undertook the first of the extensive excavations around the colossus [the Sphinx], the plan of two chambers discovered behind the Sphinx, and which contained hieroglyphic texts. Monsieur [Samuel] Birch had the thought that if one succeeded in rediscovering these two chambers, the inscriptions in question would reveal the origin of the gigantic statue. Monsieur le Duc de Luynes [Louis-Charles d'Albert, Duc de Luynes], alerted to this fact by Monsieur [Vicomte Emmanuel] de Rougé, wished, with his well known liberality, to help our compatriot [Mariette is referred to here] to pursue this curious quest, and furnished him with the funds necessary for the excavation. This act of generosity was soon followed by an allocation of funds from the French government, and Monsieur Mariette came to clear the Sphinx, which he found to be only a natural rock of which the art of the ancient Egyptians had, so to speak, finished the shapes in order to make the statue of a god. That god is Horus, and the temple where he was worshipped has been rediscovered to the southeast of the colossus [the "colossus" is the Sphinx; this temple is now called the Valley Temple]. It is an enormous square enclosure comprising a crowd of rooms with galleries made of gigantic blocks of alabaster and granite. This edifice, completely devoid of hieroglyphic inscriptions, like most of the monuments dating from the most ancient pharaohs, dates, according to all probability, from the fourth dynasty.

The Egyptians had sculpted the head of the Sphinx and filled up the large natural hollows and moulded the shapes with masonry. This colossus is found at the bottom of a sort of pit of which the lateral walls are twenty metres away from each of its sides. *Monsieur Mariette admits that in antiquity the water of the Nile could have entered this pit*. [My italics, as this is also my own idea, at which I arrived entirely independently, and which is discussed at length later in this book, in chapter 6, which I wrote before I discovered the report about Mariette, which is inserted here.] Later the Greeks had built the steps discovered by Caviglia for going down into the pit. Against the right side of the Sphinx the traveller had found a huge Osiris statue made of twenty eight pieces, reckoned to be the number of pieces into which the body of Osiris had been cut according to the Egyptian myth. [This statue seems to be otherwise unknown, and may have stood on one of the two "cupolas" beside the Sphinx on the southern side, in which case it was probably of New Kingdom, Saite, or Ptolemaic date.]

The Sphinx has been measured in all of its dimensions. Its height is 19.7 metres. In the back and across the hindquarters of the statue, Monsieur Mariette recognized the vertical shaft, the existence of which had previously been pointed out by Vansleb [ Johann Wansleben] and [Richard] Pococke, who thought that one could penetrate further down from there into existing chambers, according to their supposition, inside the colossus. This shaft, explored with care, presented at its bottom a roughly

hewn room, which was in reality just a natural fissure enlarged by the hands of man. In this room lay some fragments of wood which gave off a strong smell of resin when burnt, which led one to believe that the wood came from a sarcophagus.

One had supposed that in antiquity the Sphinx was entirely painted red, but nothing indicates that this had been so. Only the face was once covered in this colour after the reign of Ramesses the Great [sic; Rameses II], for the beard of the colossus represents an act of worship in the time of that pharaoh, over which the red had been applied.

The Greek inscriptions found near the stairs of the Sphinx tell us that this colossus bore the name of Harmakhis, the significance of which has still not been discovered.

The excavations of the Great Sphinx did not lessen the honour due to the intelligence and to the devotion of Monsieur Mariette in his magnificent discovery of the Serapeum [at Saqqara]. We need to return to this archaeological event before recapturing, as we will be doing in one of the forthcoming issues, the analysis of the works of the Academy since our last survey. 35

So now we know not only of Caviglia's excavation and study of the shaft and chamber but of Mariette's as well. Caviglia is said to have done plans of two chambers beneath the Sphinx, and we must suppose that the second one was the hollow at the bottom of the rump tunnel, since Mariette speaks of only one chamber at the bottom of the vertical shaft. As there are certainly no hieroglyphic inscriptions in the hollow of the rump tunnel, the hieroglyphic inscriptions referred to must have been inscribed on the walls of the chamber at the bottom of the vertical shaft. This would seem to indicate a date that must be later than the Fourth Dynasty, and hence not contemporary with Chephren. In fact, there is every reason to believe that this vertical shaft is what archaeologists call an "intruded grave," thrust down into an ancient monument at a much later time. But it must have been the grave of a late pharaoh, since no one less than a pharaoh would have dared to give himself a grave under such a prominent monument as the Sphinx. Perhaps it was indeed the pharaoh known to the Greeks as Amasis, so the report of Pliny that the Sphinx was his grave would actually be correct. Amasis was a late pharaoh who reigned 570-526 BC during the Twenty-sixth Dynasty, which is known as the Saite Period. This was a period when there was a great preoccupation with and reverence for the most ancient monuments, a social and cultural tendency known as "archaizing," rather like the European Romantic movement, when picturesque Greek and Roman ruins were idealized. Amasis is just the sort of late pharaoh who would have intruded his own grave into the Sphinx. So it may well be that the vertical shaft and chamber below were cut in 525 BC, and that the vertical shaft was placed at the precise spot where a much earlier top entrance to the rump tunnel had existed. If this was the case, the burial was probably not cut more sensibly in the base of the Sphinx because that base was still covered with sand. Indeed, since the Persians conquered Egypt shortly after the death of Amasis, and they pillaged and despoiled much of Egypt when they did so, it is highly likely that any such grave of Amasis would have been entered and robbed within a generation of his death. On the other hand, of course, the shaft and chamber may well have been much older, and the mention of the name of Amasis by Pliny may be entirely erroneous and misleading. If we could get into the chamber again, we could doubtless read the hieroglyphic inscriptions, and then we would probably know whose tomb it was. Or, there is one more alternative possibility: if Caviglia's missing papers could be located at Florence or elsewhere, he may well have copied down some of the inscriptions in his notes accompanying the plans.

My friend Stefano Greco and I have searched for these papers in Italy for more than a year. We did some searching when we were together in Florence in early 2007 but were unsuccessful. Stefano has

continued the search, but so far with no success. He did, however, discover a rare book, which seems to be the only surviving copy in the world, as no other is known anywhere. It is a forgotten booklet written by an Italian friend of Caviglia's named Annibale Brandi, identified by his initials "A.B.," and privately published by him in Livorno in 1823. This booklet is entitled *Descrizione compendiosa delle piramidi di* Giza in Egitto (Compendious Description of the Pyramids of Giza in Egypt). Most of it is devoted to describing Caviglia's astonishing work and findings inside the Great Pyramid, of which he cleared the entire Descending Passage of rubbish (several hundred feet of it!), entered the subterranean chamber for the first time since antiquity, and cleared it, and also descended the "well shaft" by dangling 175 feet on a rope. Caviglia was a determined and intrepid man! At the end of the booklet is an account of Caviglia's work at the Sphinx, which Brandi calls "the Andro-Sphinx" because of its having the head of a man. Although this previously unknown account is interesting, it does not mention the chamber beneath the Sphinx. Presumably it was entered by Caviglia only after this particular friend had returned to Italy, or otherwise Caviglia might have sworn his friend to secrecy about the subterranean chamber beneath the Sphinx. Stefano has translated the latter portion of this booklet that refers to the Sphinx, and it is published here as appendix 4. This text contains the shocking information that the entire text of the Dream Stela was intact at the time that it was excavated by Caviglia. Today, the bottom half of the inscription is lost, and most of that was lost (but for a few fragments, now gone) by the time Henry Salt carefully copied down what was left. Salt's drawing is shown in figure 3.7, and that contains much more than survives today. The inference to be drawn from this is that after the departure of Caviglia from Egypt, the most severe damage was inflicted on the Dream Stela intentionally, and the bottom half of the text was obliterated by someone wishing to destroy it, perhaps for religious reasons, as a text relating to an "idol." Salt probably made his careful drawing of what was left because he was afraid the whole text might at any moment be defaced (as indeed more of it was), so he wanted to record what remained to preserve the information for posterity, even though he could not read it. (We must remember that at this time no one could yet read hieroglyphics, so no one had any idea what the Dream Stela's text said.)

unexpectedly discovering the sole surviving copy of Brandi's privately printed booklet in Italian, the British Museum published a booklet containing a discovery of its own, entitled *The Sphinx Revealed: A* Forgotten Record of Pioneering Excavations.  $\frac{36}{2}$  Five years earlier, in the spring of 2002, the Egyptian Department of the British Museum had to move its offices, and after they settled into their new location, the personnel (presumably the two scholars Patricia Usick and Deborah Manley, the authors of the published booklet) noticed a couple of interesting old bound books sitting around. One contained a manuscript and the other contained its accompanying drawings. These had been in the department for at least 175 years, and no one had paid any attention to them, except that someone in the nineteenth century had taken great care to preserve them and have them carefully bound and even gilt, and had seen to it that they were cataloged. (This may well have been Sir Edward Wallis Budge, the Victorian head of the department, who was a very serious and devoted scholar.) The two authors tactfully refer to the shameful ignoring of this material for nearly two centuries by saying that it had "never been studied in depth and many of the illustrations appeared to be otherwise unknown." That is presumably a way of avoiding criticizing their past and present colleagues too harshly, and avoiding making professional enemies. (Academics have to behave like this all the time in self-protection, for there is no sphere of human activity more vicious than the academic world.) The history of these volumes shows the dangers of sole copies of important material languishing in the private offices of museums where no one has access to

them but the staff. Usick and Manley clearly saw the need to take action, and I hope they are not hated too much by their colleagues for daring to do so. But it now means that the rest of us, who are mere lowly

In 2007, at the same time that Stefano and I were searching for Caviglia's notes in Italy and

uninitiated folk who are not allowed into the inner sanctum of the Egyptian Department, can read what they have been hiding away since at least 1827. If the material had been deposited in the British Library's Manuscript Collection where it belonged, it would probably have been seen and studied by many scholars long ago.

Fortunately, the British Museum Press agreed to publish this important material, although the illustrations are so poorly reproduced that they all look as if they are viewed through a layer of mud. They are, how shall I say it, a kind of dirty dark gray. Clearly, the press does not realize that we are living in the twenty-first century, when there are such things as modern printing facilities. There is no excuse for the scans that were used being printed in such an appalling and semivisible condition. It is really very difficult to make out the detail in many of these drawings.

The text and drawings are those of none other than Henry Salt! They are entitled, on a manuscript title page bound in front of them, *Memoir on Pyramids and Sphinx by H. Salt, Esqr.* and dated on the title page 1821. This is the manuscript record that Salt intended for official publication in London of the excavation of the Sphinx by Caviglia, and it superseded the interim publication based on his notes in the *Quarterly Review* in 1818 (see endnote 22 in chapter 1). But it was never printed until now, although it needs to be stressed that some of its contents were word for word the same as material that had appeared in the *Quarterly Review*, so not all of it is new. Salt sent it from Egypt; he died six years later, and nobody did anything to bring it out. Two of his colleagues in London went through it and made a lot of textual editing changes, most of them unhelpful and in a style far inferior to Salt's own. (These changes have been carefully included in the British Museum publication by use of italics, because Usick and Manley have been very conscientious and done an excellent, scholarly job.) And then nothing happened and the whole thing sat around in the department's office and was ignored until 2002.

The frontispiece of the British Museum publication is a portrait drawing of Caviglia "in 1827, drawn by H. Salt from life," which is preserved in the Bodleian Library. I was not previously aware of the existence of this drawing, strangely preserved by an archive acquired by the National Trust and deposited in the Bodleian. The archive is that of the manuscripts of Sir Gardner Wilkinson (1797–1875), which were finally cataloged and opened to public access for the first time in Oxford in 2001. In that case, it took a mere 126 years for the material to be made available, which greatly undercuts the British Museum's 175-year availability rate. Clearly, Egyptological resources move exceedingly rapidly when judged by the standard of the ages, and in comparison to the time elapsed since the Fourth Dynasty. Indeed, one might justly and reliably say that Egyptological material is most definitely made public at a speed more rapid than the movement of the tectonic plates of the Earth, whatever skeptics might think.

It is unfortunate that the portrait of Caviglia as reproduced by the British Museum Press looks as if someone had just turned the lights out, and it is being made out dimly by some light leaking in from the next room.

The account by Salt also does not mention the chamber beneath the Sphinx. I am convinced that Caviglia had reservations about Salt, who intruded on his work and joined him by offering some funding, and that Caviglia did not reveal all of his activities to him. The newly published account contains comments by Salt about Caviglia's determination to find a "door" in the Sphinx, however. Although Salt points out that Caviglia employed as many as one hundred laborers daily, he also points out that some of Caviglia's activities "were carried on by a single individual [i.e., himself], attended occasionally only by one soldier." This reveals that Caviglia did a lot of things entirely alone and could easily keep things to himself if he wished. He never seems to have been fully in Salt's confidence, and the only part of the Sphinx work that was fully and completely open to inspection was in front of the Sphinx. But even there,

where the entry to the subterranean chamber seen in figure 1.29 must unquestionably have been exposed, since clearance was made to bedrock and it could not have been missed, not a word appeared in any of Salt's reports about its existence. This leads to only two possible conclusions: either Caviglia found it and covered it up to keep it secret or Salt did know of it but chose to keep it secret himself. The latter seems more likely, as Count de Forbin was most likely referring to this chamber in front of the Sphinx when he made his accusations that Salt was blocking up passages and openings so that no one could investigate them. If we could find the missing Caviglia papers, we could probably find Caviglia's own report on this chamber, in addition to his description of the burial chamber at the haunches that Cottrell discovered in those papers in 1833.

Later in this book, the newly published Salt material will be mentioned again, because it includes the original drawing he made, the one engraved for the *Quarterly Review*, of a carved inscription (long since destroyed) that was found by Caviglia on the middle toe of the left paw of the Sphinx.<sup>40</sup> This reveals some information that will later be seen to be of the greatest possible interest to us in trying to determine what the Sphinx actually was and why it was created. But that is for a later stage of our quest, and is to be found in chapter 6.

In 1853, Mariette had earlier written to the French Egyptologist Viscount Emmanuel de Rougé, mentioning the subterranean chamber beneath the haunches of the Sphinx as follows: "The Egyptians remedied these faults [holes in the rock] by covering the entire body of the monument with two layers of masonry. The first, which touches the rock, was intended to fill up the considerable cavities which occurred in the stone. These cavities are numerous; I came across one at the commencement of the thigh, into which I penetrated along with several people. It is without doubt the one which Father Vansleb [Wansleben] took to be a mortuary chamber."

These notices by Mariette were not the last time the vertical shaft and the burial chamber beneath the Sphinx were mentioned in print. The next occasion was in 1897, in an extraordinary article by the distinguished archaeologist Ludwig Borchardt, who for decades was the director of the German Institute in Cairo. I have carefully translated this entire article and reproduce it in full in appendix 2, not because of its mention of the shaft and chamber, but because I am convinced that Borchardt's unusual theory about the dating of the Sphinx has an unexpected relevance, as I explain at length in chapter 4. Borchardt's theory has been dismissed until now, but I believe it needs to be resurrected, because it is "true" in a way he never imagined. But for the moment we are concerned only with his comments on the vertical shaft and the subterranean chamber. The article to which I refer is a rare one entitled (in translation) "Concerning the Age of the Sphinx at Giza," and it appeared in an obscure German scholarly journal. <sup>42</sup> I have been extremely fortunate to obtain an original offprint of this article, which few people alive today have ever seen, and which seems to be largely unknown in Egyptological circles today.

The main purpose of Borchardt's article was to discuss the age of the Sphinx, and the vertical shaft and subterranean chamber are mentioned only as part of a list of features contributing to an argument. The first mention is as follows: "The occurrence of two vertical shafts on the back of the Sphinx, one of which ends in a burial chamber, in which coffin boards have been found. From this we can infer the earlier existence of a mastaba on the back of the Sphinx."

This interpretation of a mastaba (burial edifice) having preceded the carving of the Sphinx, which then incorporated it, is part of Borchardt's argument about the true age of the Sphinx. He then makes further remarks elaborating on this notion, in the context of his belief that the Sphinx was carved by order of Pharaoh Amenembet III of the Middle Kingdom, who reigned from 1818 to 1773 BC:

One could imagine the history of the Sphinx in general, mixed with some guesses, in the following manner:

The Sphinx was hacked out of the bedrock, perhaps by Amenemhet III, by destroying one of the mastabas standing on a hill, which now constitutes the back of the Sphinx. And partly by building it up with ashlar blocks. It shows the king in the shape of a prostrate lion with a human head—in front of the chest with a divine image, perhaps of Harmachis or Khepra. When later the monument was largely buried, then Thutmosis IV had it cleared for the first time. In the stela celebrating this fact we find already the mixing of the meaning of the image of the Sphinx itself with the divine image in front of his chest. Perhaps it was then that the braided divine beard was added to the image. The Sphinx was partially freed from the sand in the nineteenth Dynasty.

In a later time, the Sphinx was surrounded by a high brick wall in order to protect him from the drifting sand. From the east, a large staircase led down to the small chapel in front of the divine image in front of the chest. All these means of protection have not helped a lot. In this century it was necessary to dig him out again repeatedly, last in 1883, and actually it would be necessary again today. 44

Later in this book we shall see why Borchardt's strange theory about the Sphinx having been carved in the time of Pharaoh Amenemhet III should be looked at more carefully. The reason is rather unexpected but may be crucially important. However, it is not surprising that Borchardt's article has lapsed into total obscurity today, since there is probably no one alive who could possibly accept the bizarre notion that the Sphinx was carved as recently as 1773 BC. I am far from being a general champion of Ludwig Borchardt, however important much of his work may have been. He was undoubtedly arrogant and pompous to an extraordinary degree. He was also wrong about many things. But one of the greatest of ironies is that what people might be forgiven for thinking of as his greatest folly, namely the suggestion that the Sphinx dates from 1773 BC, which appears wholly absurd on the face of it, probably conceals an amazing truth, which I will explain fully in chapter 4. Borchardt's bold and meticulous analysis of certain evidence that led him to his strange conclusion must be examined very carefully indeed. But for the moment, it bears little relevance to what we are considering here.

Figure 2.11. In the New Kingdom, a pharaoh offers a miniature "sphinx" (as conceived at that time) to the god Khonsu in the Temple of Khonsu at Karnak. At this period, Khonsu was the god of the moon, and as such measured the passage of time. In earlier eras, this had been a function of Thoth. (Photo by Robert Temple)

It is interesting, though, that in the pursuit of his notion, Borchardt considered the vertical shaft and subterranean chamber sufficiently important that he was prepared to view them as primary features, and the surrounding Sphinx itself as secondary in origin! And he must have inspected what he could of the evidence very carefully indeed. Probably the shaft and chamber were again filled with sand in his time. But as we see quite clearly in the photos in figures 1.31 to 1.34, a gigantic crack had opened in the Sphinx at the point of the shaft, and the rear haunches look as if they were about to detach from the body entirely. This would have enabled anybody in Borchardt's time to form a very clear idea of the importance of this vertical shaft, which had been so prominent that it had effectively split the body of the exposed sculpture. And doubtless it was the clearance of the Sphinx from its surrounding sand and Caviglia's further clearing of the shaft and subterranean chamber(s) that precipitated the splitting away of the haunches, since all support, both internal and external, had been removed. Any damage caused by the previously mentioned Turkish Defterdar would then have been worsened by exposure and the loss of support of the surrounding sand. When Baraize filled this entire section with cement in 1926, he may have thought of himself as heroically "restoring" and saving a disintegrating monument from potential collapse.

By the time the great Egyptian archaeologist Selim Hassan came along, in the mid-1930s, and carried out the final and complete clearance of the Sphinx and total excavation of its pit and surroundings, all possibility of exploring and studying the vertical shaft and the subterranean chamber(s) had been destroyed by Baraize ten years before. Hassan was thus able to discover nothing about them. But this does not mean that he was unaware of them. Indeed, he is the last person to mention them in print, as recently as 1953. That no one has noticed that he did so is perhaps the most puzzling of all the lapses of students of the Sphinx, or perhaps I should say it is the most prominent of many acts of mass blindness and refusal to see, which I call consensus blindness, a psychological condition with its origin in animal behavior (humans being animals, however much they try to deny it, and most of their activities forming a subdivision of animal behavior). I have discussed consensus blindness at length in my earlier book, *The Crystal Sun* (2000). The belief that putting evidence in front of people's eyes will lead to recognition and

acknowledgment is naive and false. People see what they want to see, not what they are shown. That is part of the definition of the human species.

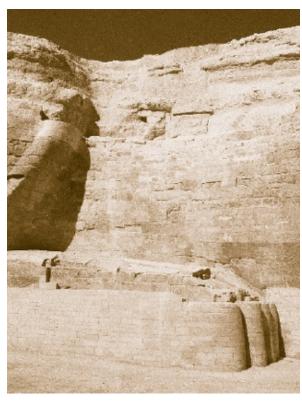

Figure 2.12. This is the south side of the Sphinx's haunch area. All the stones along the foot are from the modern restoration of the monument. The upper tip of the tail has disappeared and three courses of modern stone have been cut and added to it. In the center, the upper half of the body consists of material added by Baraize in 1926 to fill the crack that had formed at the point of the intruded vertical shaft leading to the tomb chamber directly below, as described by numerous people who entered it in earlier times. We can be confident that this filled-in vertical shaft wasn't contemporary with the carving of the Sphinx, because the tomb chamber beneath the Sphinx was covered in hieroglyphics, which was not a practice that existed prior to the Fifth Dynasty. (*Photo by Robert Temple*)

Hassan gives a great deal of attention to Ludwig Borchardt's article about the age of the Sphinx, and he even translates part of it into English (although his translation contains some unfortunate errors, because his German was not good enough; and in any case, Borchardt wrote in a difficult and old-fashioned style of the nineteenth century). Hassan spells *Amenemhet* in the form *Amenemhat*, which is an equally acceptable spelling. (Egyptian vowels were not explicitly written, and versions of words and names rendered into European languages often vary in this way as a result of changing fashions and personal preference.) Hassan naturally dismisses Borchardt's theory about this pharaoh's association with the Sphinx, and he does so in the strongest possible language:

Under the title "*Ueber das Alter des Sphinx bei Gizeh*," Borchardt has indulged in an astonishing flight of fancy! . . . It seems to me that Borchardt had gone to a great deal of trouble to prove a theory that is altogether wrong from the beginning to the end; that is if he is not having a joke with the scientific world, and indulging in a little "leg-pulling" at our expense. . . . If Borchardt was really serious about this article, then I think that of all the theories that he ever put into writing, he must have bitterly regretted having published this one!

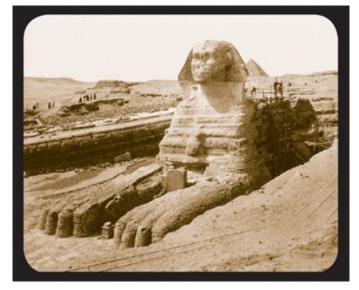

Figure 2.13. A photo of the Sphinx taken in the 1930s, during the final clearance of the monument by Selim Hassan. Railway lines for carrying away the debris are in the foreground. The face has been "restored" with modern cement filling all the gashes and holes, including the large gash over the left eye (see figures 1.16, 1.17, 1.21, and 6.4 to 6.6). The lappets, or side flaps, of the nemes headdress have been extended down to shoulder level on both sides by clearly visible modern concrete; the original stone of the lappets, which had been a bit raggedy (see figures 1.5 to 1.7; 1.20 and 1.22 as they appeard before), has been chipped away and made level for the addition of the concrete. Today the striking difference of color between the modern concrete and the old stone is no longer so obvious. This photo must have been a "proud portrait photo" taken of the just completed restoration of the face at the request of Selim Hassan, during the first day or two while the concrete was still drying and was thus still very pale. Scaffolding is in place on the northern side of the Sphinx and at the top of the back. A workmen's gangway has been made along the northern side halfway up, apparently of cement. Considerable amounts of restoration stone and cement seem to have been added later on to the northern side after this photo was taken, as this photo shows (although it is in shadow) that the northern side was extremely worn away, and the Sphinx was there narrow-bodied in a way that it is not today. In fact, the shape is more like that of a dog, receding prominently inward at the side. As for the gap at the commencement of the haunches, where the old vertical shaft to the subterranean chamber existed (as in figure 1.31, taken in 1921), we can see that it has been completely filled. Baraize plugged it with cement in 1926. Certainly, no film star was ever more botoxed or had more face-lifts than the poor Sphinx has had "cement jobs." (Collection of Robert Temple)

Figure 2.14. A photo from 1936, showing Selim Hassan's excavations in progress at the Sphinx. (Collection of Robert Temple)

Figure 2.15. This snapshot was taken by a British tourist in 1936, during the excavation and restoration of the Sphinx by Selim Hassan. This is the only known photo showing the rear of the Sphinx during this period. It shows the fantastic extent of the erosion of the natural stone of the Sphinx's rump, and reveals that Hassan was collecting fallen blocks of stone and "reconstructing" the rump with them to such a depth that the rump as we see it today protrudes by perhaps as much as 10 feet from the actual underlying stone itself. At the top of the ladder at the rear in this photo is a platform made of replaced stones big enough for at least a dozen people to stand on! Nowhere in his excavation report does Hassan mention that he did anything like this. To the left in the photo are the modern walls constructed by Baraize in 1926 to hold back the sand on the north side. Although he later demolished these, at this stage in his work Hassan was using them to anchor his planking gangways for his workmen to get across to the body of the Sphinx. It is believed that no other photographic evidence of any of this work exists, and this has never been published before. In the distance, it can be seen that the Sphinx Temple has not yet been excavated. (*Collection of Robert Temple*)

Figure 2.16. A snapshot taken by a tourist in 1936, during Selim Hassan's work on the Sphinx. The severely eroded stone of the uncovered rump is visible here from the side. As for the haunch area where the intruded shaft was, we can clearly see that Hassan erected special scaffolding to attend to that precise area. He must have found it necessary to add further filling and patching to Baraize's efforts of ten years before to fill in the broken-off haunch and smooth out the surface of the monument, restoring it to look like a single piece of sculpture again. The scaffolding erected in the front of the Sphinx has a platform used by masons to smear modern cement over the surface of the entire neck of the Sphinx. (*Collection of Robert Temple*)

Figure 2.17. Here is the scaffolding platform used for smearing the modern cement onto the Sphinx's neck in 1936. At left, we see Selim Hassan's southern gangway descending from the Chephren Causeway into the Sphinx Pit on that side. (*Collection of* 

## Robert Temple)

Figure 2.18. An engraving of the Sphinx from the nineteenth century. The prominent crack in the rear, by which one could descend to the chamber beneath, is highlighted here. (Collection of Robert Temple)

Within the extensive quotes from Borchardt, Hassan includes the description of the "two vertical shafts in the back of the Sphinx, one of which ends in a tomb chamber, and contained coffin boards."

With this explicit information included in the most recent and definitive excavation report on the Sphinx by its modern excavator, why has no one noticed or commented on it? Hassan certainly does not dismiss this information in the way he dismisses the theory of the Sphinx's association with Amenemhet III. It is there for all to see.

And so this brings us up to a time that is more or less modern; 1953 is not all that long ago. There are still people alive who knew Hassan. Between a third and half of the world's present population must have been alive in 1953. It is not an inaccessible era, lost in the mists of time.

And yet all the "experts" on the Sphinx are in total ignorance of every piece of evidence that I have just presented, knowing nothing of a total of 281 years of discussion of the vertical shaft and subterranean chamber beneath the haunches of the Sphinx. The blindness to this question reminds me of the mass blindness to all evidence of ancient optical technology, which I reported at such length in The Crystal Sun. 47 In that book I described my discovery of more than 450 ancient optical artifacts and lenses, and published photos of many of them. Evidence of the use of magnifying aids goes back to 3300 BC in predynastic Egypt! And yet all "experts" in the world were ignorant of this. They thought there were no optical artifacts at all. And this was despite the fact that many ancient lenses are prominently on display in museums around the world. The evidence is all around us, and can readily be seen in Athens, Cairo, London, and elsewhere, by any tourist. But no one could *see* it, despite the fact that it was in front of them. This was because they were convinced it could not exist. Physical evidence, even hundreds of items of it, is useless when people have no mental faculties to allow them to register it. It may register on the optic nerve, it may be perceived by the retina, but the mind is a blank. No impression is made. This case history of what I have named "consensus blindness" is most alarming; it shows that humanity is a strange species indeed, in which massive amounts of evidence may be thrust under the noses of us humans and be totally ignored. We are a stubborn lot. We just refuse to see what we are convinced cannot be seen. It is really the reverse of "The Emperor's New Clothes," the fable in which people see what isn't there. The real problems of humanity lie in the opposite direction, in *not* seeing what is there. And we have a classic case of this now, in the refusal to register in their minds what many Egyptologists and others must have read, namely that there was once a vertical shaft in the Sphinx that led to a subterranean chamber beneath the haunches. By some weird unspoken consensus, everyone has agreed *not to know this*.

So where do we stand? We know precisely where the vertical shaft was. We have exact measurements of its location. We know the exact dimensions of the opening. We know the nature of the chamber. We know that it contained an ancient burial. We know that the walls were inscribed with hieroglyphics. Not

only could these reveal whose burial was in the chamber, but presumably some pieces of the coffin boards are still in the chamber and could be carbon-dated.

It is possible that the cement that Baraize smeared into the crack in the haunches and stuffed into those portions of the shaft that were accessible has not filled the chamber. There must have been a great deal of sand filling the chamber and much of the shaft, and this would have protected the rock from damage caused by the cement. The chamber could thus be reopened. Probably the whole chamber and much of the shaft itself are intact underneath the restoration of Baraize. The evidence that I have presented is overwhelming. There is no doubt that crucial information about the Sphinx could be recovered if we could reopen the shaft and chamber somehow. But how could we do it without damaging the Sphinx? The Sphinx is a proud symbol of the modern nation of Egypt. It has been laboriously restored in recent years and is one of the main tourist attractions of Egypt. Although the authorities did not hesitate to cover it with scaffolding for years, and equally do not hesitate to shut major sites like the interior of the Great Pyramid for a year or more at a time for restoration, the question arises: Would anyone be prepared to try to enter the shaft and chamber now that the Sphinx is meant to be completely perfect and fully restored? If they aren't prepared to break through Baraize's cement at the upper end of the ascending rump tunnel, which could be done from inside without anybody seeing anything, will they be willing to undertake more drastic investigation on the outside? There are more than archaeological considerations involved. This is really a political and prestige issue. The Sphinx is a political symbol today, representing the glory of the nation.

Figure 2.19. This postcard, mailed from Port Said to Germany in 1929, shows the Sphinx at a crucial transitional stage. Baraize has obviously finished his clearance in 1926, but has not yet erected his scaffolding or commenced his violent "restoration." The deep crack of the detached rump and the crack near the front of the body are evident. There is also a crack in the middle of the body that can be seen here. Old restoration stones, presumably of New Kingdom (post–Thutmose IV), Ptolemaic, and Roman date, have fallen off the side of the Sphinx and are temporarily piled up close beside it. These were later cemented back into place by Baraize, though he obviously had to guess at their placing, since he was drawing them from a heap. The ravaged core of the Sphinx's side may be seen here in a largely bare state, though along the lower half more ancient repair blocks (presumably of Old Kingdom date) of larger size can be made out, which are still adhering and are of superior workmanship. This shows that older repair blocks from previous epochs underlie many of the historical repair blocks visible on the surface of the Sphinx's body today, many of which in turn are covered by recent ones. This observation agrees with the clear "double-skin" of restoration shown on the Sphinx's rump in figure 5.14. When trying to estimate the original width and contours of the Sphinx's sides, we must remember that two or even three later skins exist for most of the surface, along with cement in-fillings and countless "patches," and that all these have been shaped according to the opinions of the restorers, creating contours that met with their approval at various epochs. (Collection of Robert Temple)

It is also a nice little earner for the tourist business. And Egypt certainly needs its tourists as it struggles economically.

But on the other hand, the Egyptian authorities have to weigh the advantages of making a discovery of a truly sensational nature. They know enough about international publicity to realize that if they were to open and study and photograph a chamber beneath the Sphinx and decipher and publish the hieroglyphic inscriptions on its walls, and possibly even date a coffin board, they would cause so much excitement that the result could easily be a doubling or even a trebling of the number of foreign tourists suddenly rushing to Giza, and the Egyptian economy could benefit by many tens of millions of extra dollars per year.

So what will they do?

Finally, I must mention again that in more recent times, there has been some scientific survey evidence carried out to try to find underground passages and chambers beneath the Sphinx. The work that has taken place commenced in the 1970s. Results of these first studies were published in 1977 in a booklet entitled *Applications of Modern Sensing Techniques to Egyptology.* In this booklet, the authors write that preliminary work in 1974 showed that the use of radar was ineffective in searching for underground chambers and tunnels: "The fact that radar cannot answer these questions was discouraging to us after our 1974 work; however, the present results using acoustic methods and resistivity [measurement of resistance to the flow of electricity] methods reopen many possibilities for further, efficient surveying of Giza."

Figure 2.20. Here I am standing in front of a paw of the Sphinx, but you would never know it, because the myriad of tiny limestone blocks behind me are all brand-new. This type of "restoration" of the Sphinx was done not for archaeological purposes but to render a national monument fit for viewing by millions of tourists, as customers of the Egyptian economy and as "consumers" of the Sphinx. There is certainly no reason to believe that this restoration of the forelegs and paws of the Sphinx accurately reflects their original appearance, or that the earlier restoration of the forelegs and paws by the Romans (who also used small limestone blocks) was accurate either. In this photo I am wearing my badge as a delegate to the Eighth International Congress of Egyptologists, which took place in Cairo in 2000, at which time I made one of my visits to the Sphinx Pit. (*Photo by Olivia Temple*)

Figure 2.21. I took this view of the Sphinx's head from its feet, shortly after sunrise. It shows several features very clearly that are not readily visible to tourists, who are not allowed this close except with special permission. The lappets, or side flaps, of the headdress have been "reconstituted" since the 1930s. Blocks of concrete have been placed under them, so that at a distance it looks as if they are complete and extend all the way to the shoulders. In the old photos shown in figures 1.5 to 1.7, 1.16, 1.17, and 1.20 to 1.22, it is very clear that until this was done, the lappets were in tatters and the bottoms of them no longer existed at all. Another feature clearly shown here is that the neck has been entirely reconstituted by "reconstruction" in the most barbaric and primitive fashion. It now consists merely of layer upon layer of modern cement smeared roughly, and not even smoothly, to give some kind of approximate impression of a neck, which is not shaped with any care. The nose was broken off by a Muslim fanatic in the tenth century, not shot off by Napoleon's soldiers as the false story goes. You can see that various fissures in the face (which are clearly visible in the old photos in figures 1.16, 1.17, and 1.21) have been filled in with modern cement. The other repairs may be seen very clearly by comparing this photo with figure 1.22. From the evidence, it is clear that the Sphinx today is an absolute mess, a botched job of appallingly bad reconstruction, such that the grand monument has been turned into a kind of Disneyland parody of itself. I hope that one day a restoration of the Sphinx can take place that will lend the dignity and taste to the monument that these ugly disfigurements have gone so far to destroy. However, it will not be easy, because the modern cement and concrete are hard and the native stone is fragile. (*Photo by Robert Temple*)

Figure 2.22. This is a close-up of limestone repair blocks on the Sphinx, which are generally believed to date from the Old Kingdom. (The pale one at top left is a modern replacement block.) I should point out certain details about these blocks. One is that several of the blocks are cut with interlock niches to grip blocks higher up and to one side, as we see with two successive blocks at bottom left in the photo, for instance; they are not cut as simple rectangles but can grip above with their little niches. This technique was often used with large blocks during the Old Kingdom (as can be seen in many places in the adjoining Valley Temple) and indicates a definite finesse in building techniques. Some of the blocks, especially at the bottom of the photo, have negligible mortar and fit together extremely tightly, as one would expect of Old Kingdom blocks. To have achieved this while covering a curved surface at the same time is a considerable feat and shows superior skill, skill that did not exist after the Old Kingdom. On the other hand, the higher courses of stone shown here have substantial mortar, which has clearly been inserted later on. I believe that the blocks in the upper half of the photo have all been retrieved and relaid after having fallen to the ground. This may have taken place at any time from the Middle Kingdom to Roman times. The mortar appears to be so crude that it has probably also been repointed, possibly even by Baraize or Selim Hassan as recently as the 1920s or 1930s. The point of all this is that large portions of the rear of the Sphinx are still covered in these superior blocks of apparent Old Kingdom origin, and they were obviously placed there to cover erosion of the stone body of the Sphinx. But if this is the case, how can the Sphinx have been carved in the Old Kingdom? There is a clear contradiction here: the Sphinx is said to have been carved on the orders of either Cheops or Chephren, of the Fourth Dynasty of the Old Kingdom, and yet repair blocks dating from about that time seem to survive on the Sphinx. How is that? Do you normally repair something that you have just made? The Inventory Stela (see figures 3.5 to 3.8) excavated at Giza states that Cheops *repaired* the Sphinx. Although the Inventory Stela is a late stela that does not date from the Old Kingdom, some have suggested that portions of it repeat an older text from an earlier inscription. The popular idea that the Sphinx is thousands of years older than Cheops is absurd and cannot possibly be true (and I show in this book in chapter 6 why the "ancient rain" theory is false), but it is possible that the Sphinx is older than the time of Cheops by as much as several centuries. And that poses even more difficult problems for the origin of Egyptian high civilization, because then we are dealing with a real problem rather than a fantasy problem, and reality is always tougher to handle than fantasy. The idea that the Sphinx is of immense and fantastic antiquity is as remote and unreal as a hedge fund, whereas the fact that the Sphinx was repaired at the same time that it was supposed to have been carved is as real and difficult to handle as your own personal bank account. (Photo by Robert Temple) Opposite top: Figure 2.24. This photo of the Sphinx's right hind paw shows clearly how artificial it is and reveals the many layers of repair blocks. The pale small blocks are the new ones, made of freshly cut limestone and placed there in recent years to create a coherent tourist attraction that "looks right" from a distance. The protruding element behind the paw is the Sphinx's tail, which, as can be seen, consists now entirely of reconstruction blocks dating from different periods (the pale ones being the recent ones). To the right of the tail, and in the center of the photo above the paw, is the former giant crack in the Sphinx's body that can be seen so clearly in the 1921 photo shown in figure 1.31, before it was filled. In 1926, Baraize filled the crack by pouring in tons of cement and then covered over the cement with small limestone blocks (see at the top of this photo in the central portion). Below those, just above the paw, are a few courses of what appear to be older repair blocks, and to the left of them recent ones that are almost white, which have been stuffed in where some holes had begun to reappear since the 1920s. Those blocks to the left of the tail in this photo, which are large and worn, are thought to date from the

Old Kingdom repairs. The small dark blocks at top right in this photo are probably Roman.

Figure 2.23. A close-up view of the left lappet of the headdress of the Sphinx. The bottom half of the lappet consists of a complex series of small restoration blocks, with a thin layer of slabs over them, followed by modern concrete up to the level of the original top half of the lappet. The effect from a distance is to make the lappet appear to be complete. (*Photo by Robert Temple*)

Figure 2.24. This photo of the Sphinx's right hind paw shows clearly how artificial it is and reveals the many layers of repair blocks. The pale small blocks are the new ones, made of freshly cut limestone and placed there in recent years to create a coherent tourist attraction that "looks right" from a distance. The protruding element behind the paw is the Sphinx's tail, which, as can be seen, consists now entirely of reconstruction blocks dating from different periods (the pale ones being the recent ones). To the right of the tail, and in the center of the photo above the paw, is the former giant crack in the Sphinx's body that can be seen so clearly in the 1921 photo shown in figure 1.31, before it was filled. In 1926, Baraize filled the crack by pouring in tons of cement and then covered over the cement with small limestone blocks (see at the top of this photo in the central portion). Below those, just above the paw, are a few courses of what appear to be older repair blocks, and to the left of them recent ones that are almost white, which have been stuffed in where some holes had begun to reappear since the 1920s. Those blocks to the left of the tail in this photo, which are large and worn, are thought to date from the Old Kingdom repairs. The small dark blocks at top right in this photo are probably Roman.

Figure 2.25. The Sphinx as seen from the roof of the Valley Temple, with the Great Pyramid in the distance. At the Sphinx's feet is the modern wooden ramp that has been constructed to lead select visitors into the Sphinx Pit (it is closed to normal tourists). The long legs and the paws are entirely a work of restoration, small modern limestone blocks having supplemented the Roman ones. Even two thousand years ago, the legs and paws were so worn away that they had to be entirely rebuilt. The outer casing of the rear paw has been similarly reconstructed by modern blocks. The main purpose of the Sphinx today is to act as a national monument and to service the tourist industry. I have never seen a photo of the Sphinx from this viewpoint published before, since no one is normally allowed onto the roof of the Valley Temple. (*Photo by Robert Temple*)

Figure 2.26. A brooding Sphinx. (Photo by Robert Temple)

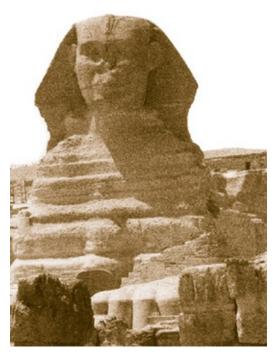

Figure 2.27. A photo of the Sphinx taken from inside the Sphinx Temple, which is closed to tourists. The remains of the uraeus (insignia of a royal serpent rearing its head) on the forehead of the Sphinx is seen particularly clearly from here, whereas it is usually hard to see it properly. The west wall of the Sphinx Temple, which faced the feet of the Sphinx, formed an eastern barrier for the water in the Sphinx moat during the Old Kingdom period. By no later than 2000 BC, the Sphinx Temple was entirely buried

Figure 2.28. This rear right foot of the Sphinx is heavily restored by small, modern limestone blocks to make the monument presentable for tourists. (*Photo by Robert Temple*)

Figure 2.29. The filled-in waist on the right (southern) side of the Sphinx. The top half of the Sphinx's body seen in this photo is the original carved stone figure, deeply eroded in a series of horizontal stripes, whereas the bottom half is composed entirely of reconstruction blocks from different periods. These have had the effect of filling in the waist of the Sphinx, which was once narrow, thus disguising the doglike appearance and making the body appear to be more massive and leonine. At the left of the photo, the angle of the light on the tail enables us to see clearly that this portion of the tail at least is made entirely of blocks, and does not contain any carved stone core at all. The tail may therefore not be an original feature of the Sphinx but could have been added at a later period as part of a "lionizing" process. In any case, if there were an original tail, what we have now is largely or wholly a replacement, or "tail transplant." (*Photo by Robert Temple*)

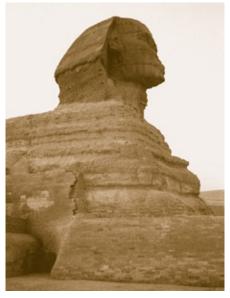

Figure 2.30. At dusk, when the glare of the sun has subsided, a clearer view is possible of the contrasting materials that now make up the outer surface of the "restored" Sphinx. Here we see that the elbow of the Sphinx is entirely covered in small modern

limestone restoration blocks. The chest is the original weathered bedrock. The bottom half of the headdress down to the neck is of modern blocks and concrete, smeared with modern cement. (*Photo by Robert Temple*)

They then published a very brief summary of attempts to search for underground chambers and tunnels in the Sphinx precinct. They write that they found "five areas of interest." They believed they detected cavities in front of the forepaws of the Sphinx and also, as quoted in the preceding chapter:

Behind the rear paws (*northwest end*) we ran two traverses . . . . Both traverses indicate an anomaly that could possibly be due to a tunnel aligned northwest to southeast.

Another anomaly exists in the middle of the south side near a square cupola added apparently in Roman times. This anomaly was verified by two overlapping traverses. . . . When the electrodes were moved 2 m away from the previous traverse, the anomaly decreased in value. This is typical of the behavior expected from a vertical shaft. . . . The resistivity anomalies we found around the Sphinx are not defined sufficiently to allow us any absolutely certain conclusions, and we feel that a more detailed survey should be conducted. 50

These results were certainly suggestive, and at least two of the findings could well have been shafts or tunnels linked or connected to the vertical shaft in the haunches and the chamber beneath it, which of course were unknown to these researchers, an Egyptian physicist named Ali Helmi Moussa and an American physicist named Lambert Dolphin from the Radio Physics Laboratory of the Stanford Research Institute in California.

What is of particular interest is their finding that there appeared to be "an anomaly" that was "behind the rear paws" and that "could possibly be due to a tunnel aligned northwest to southeast." This anomaly falls along a crack in the bedrock that does indeed run northwest to southeast, and that is clearly portrayed in the plan drawn by my friend Professor Lal Gauri, which is reproduced here as figure 1.30 and shows the Sphinx from above looking down. Of this, Lal says: "Dissolution of the limestone by water along the joints has produced cavities. . . . The shaft passing through the middle of the Sphinx as seen from above is one such large cavity. . . . Since these cavities strictly follow the joint patterns [of the limestone bedrock] and are, in most cases, not connected to the surface, it seems that they have been formed by underground water." <sup>51</sup>

The limestone bedrock of the entire Giza Plateau is unquestionably riddled with cavities. However, it should be noted from Lal Gauri's drawing that this particular cavity beneath the Sphinx runs horizontally below the surface straight through the former vertical shaft, Baraize's cement plugging of which may also be seen clearly on Lal's plan as a distinct blob with a dot in the middle. It is as if the bedrock had been cracked at this weak point by some enormous force applied to it, and it may well be that the crack occurred along the joint when the vertical shaft was intruded downward into the bedrock beneath the Sphinx for the construction of the burial chamber, which lay precisely in the path of this extended linear "cavity." Subsequently, the action of water may well have scoured out the crack to form a long hollow space, for once a crack opens in limestone, water is bound to wear it away even further over time. And one of the descriptions of the tomb chamber did mention, as we have seen earlier, that it was an enlarged natural cavity.

A second depiction of the linear crack/cavity is shown in another plan, published by Mark Lehner in the same volume of conference proceedings as the one by Lal Gauri. This drawing is reproduced here in appendix 5 as figure 10 and confirms the drawing of Gauri, although it does not show any cracking on the northwest side of the Sphinx at all, and Lehner seems to have been unaware of it. What Lehner does show

is the cracking that runs in a direction southeast from the Sphinx's right rear paw, which Lehner describes as a "Major Fissure."

Thus, we have clear evidence from the plans published by two of the leading experts on the Sphinx that there is a major crack in the bedrock commencing at the point of the former vertical shaft in the haunches of the Sphinx, and this is the same feature reported by Moussa and Lambert in 1977. It is possible that this feature is not merely a crack, fissure, or cavity enlarged by water, but is an actual tunnel leading from the burial chamber. Why not? If they put a chamber down there that was as large as the accounts inform us, then why not a tunnel as well? That our informants do not mention such a tunnel might merely indicate that the tunnel entrance from inside the chamber was concealed, and they did not notice it. Certainly, at the very least, further soundings need to be taken here. If they suggest that the "cavity" is a tunnel, then breaking down into it would lead to the burial chamber without the need for digging out Baraize's cement and going down from the top of the Sphinx's back.

Another thing we need to take seriously is the "cupola" attached to the south side of the Sphinx (see figures 2.31 to 2.33). People just accept this; no one questions it. Why? Is it not the oddest thing imaginable? Ancient sculptures do not normally have cupolas on them, like some kind of huge boil. What on Earth *is* this weird cupola? Why does no one ever challenge it and point out that it is an unacceptable anomaly? Why has no one taken the trouble to find out what is either behind or under it? Could it have been erected with an intention to conceal something or to act as an entrance to something?

Alternatively, it may have been meant to support the mysterious "statue of Osiris in 28 pieces" that was mentioned earlier by Mariette and has now disappeared. We must presume that whoever the people were who built the cupola were not just harmless cupola-lovers who simply went around building stone cupolas for fun and without a reason. So what was the reason? Why has no one ever even thought of investigating it? There is also a mini-cupola, which everyone also just blandly accepts (see figure 2.34). But what was it? In fact, there are altogether four cupolas!

In 1978, further studies were carried out at the Sphinx to follow up the intriguing results published in 1977. This work was apparently done by Lambert Dolphin, Patti Burns, and John Tanzi of the Stanford Research Institute. However, they never published their results, and in 1999 Lambert Dolphin is reported to have stated, "None of us has been able to locate our logs and printouts," even though "the 1978 resistivity work was much more thorough [than that published in 1977]." These comments are published in the book *Secret Chamber* by Robert Bauval and Simon Cox. Bauval and Cox reveal that Lambert Dolphin's work was connected with an organization called the Association for Research and Enlightenment (ARE) in Virginia, which is devoted to researching the prophecies of the psychic Edgar Cayce. Dolphin is also quoted as writing: "Hugh Lynn Cayce [son of Edgar Cayce] was a very gracious sponsor and spent considerable time with us during the time the field work was being done. He mentioned that the Cayce Foundation had less confidence in Edgar Cayce's readings [psychic readings] in archaeology as compared to his medical readings and healing work. Yet ARE had ongoing interest in and around the Sphinx. Ongoing work has in fact continued by Dr Joseph Jahoda." 54

Figure 2.31. This is the larger stone "cupola" or "booth" beside the right elbow of the Sphinx, on the southern side. What is it? No one knows. It seems to date from Roman times and may have been a base for a statue (in which case the top is missing), or a side altar base, or to conceal an entrance to the interior of the Sphinx. There are four of these bizarre protrusions from the side of the Sphinx, none of which has been explained. (*Photo by Robert Temple*)

Figure 2.32. Detail of the larger "south booth" or "south cupola" beside the Sphinx. (Photo by Robert Temple)

Figure 2.33. The top section of the large "south booth" beside the Sphinx. This is a very strange thing to be sticking out of the Sphinx, but no one ever mentions it. (*Photo by Robert Temple*)

Figure 2.34. One of the four strange stone boxes protruding from the sides of the Sphinx at the base, presumed to have been constructed during the New Kingdom, perhaps to act as statue bases. This one is the smaller of the two that are on the south side of the Sphinx. The square stones on top at right are modern reconstruction stones, as are the small limestone pieces to the left of the box on the Sphinx's body. No one has any idea as to whether the four boxes sticking out of the sides of the Sphinx at the base might have been constructed to obscure an entrance into the body or to block an entrance to a shaft. Nor has any proper study of the four boxes ever been done, to my knowledge. None of the excavators ever paid much attention to them. It seems extraordinary to me that people just seem to accept the fact that there are four stone boxes protruding from the Sphinx. You would think that archaeologists would be rushing to examine them, study them meticulously, perhaps dismantle at least one and put it back together again (which would not be difficult), just in case there is something hidden inside. But no, nobody does anything. They just sit there and everybody ignores them. No one has even inserted any probes to see if they are hollow, as far as I know. Whoever said that human beings are curious? (*Photo by Robert Temple*)

Apparently, the famous American psychic Edgar Cayce had had a vision while in a trance in 1923 that there were tunnels and chambers under the Sphinx. And that is why his son, the Cayce Foundation, and ARE were endeavoring to find them. Cayce said that this chamber would be what has come to be called "a Hall of Records," containing precious ancient documents about a lost civilization. The Cayce people were strongly supported by their friend of many years, the American Egyptologist Mark Lehner, whose first book, *Egyptian Heritage: Based on the Edgar Cayce Readings*, was a defense of Cayce's theories and psychic readings about the Sphinx and theories of Atlantis that was actually published by ARE. In later work, the Cayce people drilled a hole under the right forepaw of the Sphinx and appear to have found some evidence of a cavity in the rock at that point. But the work was stopped for reasons that are disputed. A strange account of these murky doings has been published in *Secret Chamber*, which is so confused that no matter how many times I read it, I cannot fully comprehend it, so convoluted is the whole issue.

Knowing none of the people concerned, I cannot understand why an organization in America would send a team to study something in Egypt (the expedition of 1978) and then lose the results. Does this strike anyone as odd? We are simply told (assuming the report of Bauval and Cox to be accurate): "None of us has been able to locate our logs and printouts." How many of "us" are there? How many logs, how many printouts, where were they kept? And if there were several of them, how could they *all* vanish when in the apparent custody of "all of us"? I don't get it.

A seismographer named Thomas Dobecki in 1990–1 used some seismic equipment to look for cavities underneath the Sphinx area. He says he confirmed a rectangular cavity measuring 29.5 feet by 39.4 feet under the right paw of the Sphinx. It would be interesting to investigate that further, especially as it could possibly be a further chamber reached from the small chamber between the Sphinx's paws, seen in figure 1.29. As I said earlier, it appears from comments made by Count de Forbin that Henry Salt blocked up a passage leading from the small chamber, and if so, it might well have led to just such a large chamber as the one claimed by Thomas Dobecki. I believe that this was the same location "sensed" by Edgar

Cayce. There is no a priori reason whatever why such a chamber should be assumed not to exist, even if it is only one of the natural caverns in the limestone with which the plateau is riddled.

One thing is for sure: none of the researchers of recent decades is aware of any of the material that I have presented in this chapter, so they have all been working in the dark.

There is a chamber, there is a shaft, both of which were discussed for 281 years in a whole series of publications, *but they don't know it!* 

## AN AMAZING SURVIVAL

It seems hardly credible that a story could be accurately passed from mouth to mouth for three thousand years, or seventy-five human generations. Anyone who has played the game of Chinese Whispers knows that messages get distorted incredibly quickly, and often very drastically. Chinese Whispers, for those too addicted to television and computer screens to know what it is like for a group of people to amuse themselves by playing what used to be called a "parlor game" in the days when there was still something called "social life," consists of several people sitting on chairs arranged in a circle, facing one another; the person who starts whispers a message in the ear of the person next to him or her, and this message is repeated around the entire circle of people. Finally, the last person in the circle, who is sitting next to the person who started it all, speaks out loud the message as he or she received it. The results are usually astonishing and bizarre. Suddenly all one's friends, who one assumed were highly intelligent and capable people, strike one as thickheaded or, possibly, perverse. "That wasn't what I said!" one is tempted to shout. The distortions of the message are usually so incredible that everyone has a good laugh at the result, at the same time realizing the extreme fragility of messages, which can be changed beyond recognition after just a few repetitions.

This is called "noise in the system." All messages get distorted. Nothing can be transmitted reliably if it is repeated too often; sometimes it has to be repeated only once to go awry. All of us have had the experience of a friend attributing statements to us that we have never made. Celebrities are frequently misquoted in the press, often on purpose, but sometimes just through garbling. "Noise" interrupting accurate communication even takes place within our own heads. It is called false memory syndrome. Sometimes we get things wrong but don't realize it ourselves, and really *believe* a false message. Or for emotional reasons we may be in denial and unwilling to face a truth, so we distort the message to ourselves. We say: "I never did that," even though we know we did, but by insisting to ourselves that we didn't, we come to believe it. Or we distort what we have said to cast ourselves in a more favorable light.

So when we come across incontrovertible evidence that a tale has been passed down through seventy-five generations and has retained essential accuracy, it is an event in the history of folklore that really deserves to be toasted in champagne. And that is what has happened with the Sphinx.

It was the fifteenth-century Dutch traveler Joos van Ghistele who recorded this fact, although he had no idea of the true significance of what he was recording, because it was only in the nineteenth century that the evidence came to light to prove that his information was accurate.

Here is what van Ghistele set down of the tale told to him about the Sphinx by the local inhabitants of

Giza. He was given this information in AD 1482, ten years before Columbus discovered America:

One day in those [ancient Egyptian] times a man went there to make some sacrifices; he asked of the Idol [the Sphinx] what was going to happen to him, and the head [of the Sphinx] replied to him that he would become King and master of Egypt if he wanted to follow its counsels. Thereupon the man replied that he would follow them and it happened that this man became King of Egypt as he had been told he would by the head. A little while after his coronation he returned to the place where the head was. [The full passage and reference are to be found in part 2.]

Let us keep firmly fixed in our minds that van Ghistele was told this by the locals in AD 1482. No later visitor was told this, and it is likely that van Ghistele arrived at Giza just as this tradition was at last dying out. Perhaps he overlapped with the last generation to remember the tale. But if so, it was a lucky fact that he did. By a hair's breadth the information was preserved just as the candle flickered and died.

What is the significance of this folktale? Of course, it is very clever of the locals to know that people went to offer sacrifices to the Sphinx, since we know from the excavations that have taken place between 1817 and 1970 of the vast amount of evidence that has been uncovered showing that the Sphinx was an object of veneration, to which kings as well as commoners made offerings, from New Kingdom times (circa 1800 BC) through Roman times. But a general tradition like that is not so surprising a thing for the locals to remember, and the end of Roman worship was only about a thousand years prior to van Ghistele's visit, so it was like people at Hastings saying today that William the Conqueror landed there in AD 1066. People at Hastings talking about William the Conqueror is one thing, but it would be quite another if we had the local inhabitants of Wiltshire giving us accurate accounts of what went on at Stonehenge when the trilithons were erected there, and what King So-and-so said and did about it, for that would be more than three thousand years ago, surely too long a time for any folklore to last! Or is it?

This is what is so extraordinary. The people of Giza remembered and accurately recounted a true story about a king named Thutmosis (also known as Thothmes) IV, who lived *three thousand years earlier than Joos van Ghistele's visit*.

"Well," you might say, "someone told them." Or perhaps "they learned it from books." But alas for the skeptical turn of mind, there is no way out. It cannot be avoided that the tale survived accurately for three thousand years by word of mouth, because the stela recording the story was not excavated until 1817 and could not be read until after Champollion deciphered hieroglyphics in 1821.

So it was 339 years after Joos van Ghistele was told the story about the Sphinx before the excavated evidence could even have been read by anyone, even if Champollion had made it the first text for translation, which of course he did not. There were no other records of the story in existence.

The discovery of the story in hieroglyphic form took place in 1817, when Captain Giambattista Caviglia thoroughly excavated the front of the Sphinx and found a large and impressive inscribed stone stela standing in front of the Sphinx's chest, placed there by the pharaoh of the New Kingdom period named Thutmosis (or Thothmes) IV (reigned 1425–1417 BC). Caviglia's excavation of this stela has already been discussed in the previous chapter. The news of Caviglia's discovery was first reported to the world in a trimonthly intellectual news magazine of the time called the *Quarterly Review*, published in London. In volume 19 for the year 1818, an account of the Sphinx excavations appeared in the context of a review of a new book of papers from the collection of Robert Walpole dealing with certain other discoveries in Egypt. The information was forwarded to the *Quarterly Review* from Cairo by Henry Salt, the British consul general in Egypt, whose action in sealing and suppressing some entrances and passages

at the Sphinx has already been alluded to.

Captain Caviglia was a very self-effacing character who liked to say modestly that he was merely a sea captain, but he worked harder and more passionately to excavate and discover things in Egypt at that time than any scholar. (Egyptologists as such did not yet exist, so there were no professionals in existence to be jealous of him and try to stop him.) Caviglia seems to have spoken English passably well, as he had sailed under the British flag in a merchant capacity for many years. But he did not write English. He could write letters in French, some of which survive (and one about the Sphinx I have copied from the manuscript and reproduced in full, in translation, in part 2), but his reports were all written in Italian and handed to Henry Salt. Caviglia quaintly called Henry Salt "Enrico," which is the Italian form of Henry. I have looked through these reports, which are preserved in the Manuscripts Collections of the British Library among the Salt Papers. They are written in a very courtly and polite manner characteristic even then of a very old-fashioned type of man. Caviglia was legally entitled under the terms of his agreement with the Egyptian authorities to keep everything that he found in the course of his extensive excavations of the Sphinx, but he very generously retained nothing. He donated everything to the British Museum as a token of thanks to the British people under whose flag he had sailed for so long. This is why the British Museum today has a part of the Sphinx's beard, among countless other things. Unfortunately, most or all of these items have languished in the basement since they reached London 180 years ago. The fragment of the Sphinx's beard has occasionally been a subject of dispute, with people pointing out that it should be returned to the Sphinx, especially as another fragment is in Cairo. But people who say this do not know the facts. The beard was affixed to the Sphinx by the very pharaoh of the New Kingdom whose story we will shortly narrate. It was never part of the original Sphinx, and to "return it to the Sphinx" would be ridiculous. It would make sense to join the two beard fragments, of course, which is another matter. But even when you had done that, there wouldn't be much to see. If you've seen one Egyptian beard, you've seen them all. The Cairo fragments of the Sphinx's beard are pictured in figures 3.1 and 3.2; the latter shows that the fragments that remained in Cairo were smashed, and only portions are left.

Since Caviglia could not write in English, he left the English publication of his exploits to Salt, which is why everything is in the third person, and there is no first-person narrative available in English about what Caviglia actually did. I wish Caviglia's original accounts could be found and then translated from Italian into English and published, as they should form a part of the official printed record of the history of Egyptology. My friend Stefano Greco and I have done this for a previously unknown third-person account of Caviglia's excavations privately printed in Italy at the time by Caviglia's friend Annibale Brandi, of which only one copy appears to survive, and Stefano found it. The section of this booklet dealing with the Sphinx, translated into English, is in appendix 4.

In the *Quarterly Review* account, even Henry Salt is referred to in the third person—"Mr. Salt says"—indicating that someone else took the documents forwarded by Salt and edited them, incorporating comments from Salt's letters, who evidently stayed in Cairo while this was all being prepared for publication in London.<sup>1</sup>

Figure 3.1. These are fragments of the Sphinx's beard that were excavated by Giambattista Caviglia in 1817 and drawn by Henry Salt at the time. It can readily be seen that this beard was a New Kingdom addition to the Sphinx and that it bore hieroglyphics and pictures, which was completely different from the style of the Old Kingdom period. The plaited pattern is meant to represent the plaited hair of the beard. The top portions show a New Kingdom pharaoh, doubtless meant to represent Thutmosis IV, kneeling and making an offering. The hieroglyph *ankh* is seen at top left, although it is broken off at the bottom. This portion of the fragmentary inscription, continued in the second fragment, ends in the letter *f*. The third fragment shows what is presumably the pharaoh facing the other way with an offering. To his right are two scepters. The one on the right (with a break in the middle) is known as the *uas* scepter, as can be seen by its forked base, which was used in shadow-measuring. This drawing is found in *Operations Carried On at the Pyramids of Gizeh in 1837* by Colonel Howard Vyse and John S. Perring, London, 1842, third appendix volume. (*Collection of Robert Temple*)

Figure 3.2. This is a photo of portions stuck together of what was once the top fragment of the Sphinx's beard; the condition of the fragment before it was further broken by archaeologists is shown in figure 3.1 above. To the right, the kneeling pharaoh making an offering is now lacking his head, which he still possessed in 1817. Many excavated objects suffer further damage after they are found, and this is an example. The German caption says: "Fragments of the divine beard of the Sphinx." This is reproduced from plate 17 of Herbert Ricke's *Der Harmachistempel des Chefren in Giseh* (*The Harmachis Temple of Chephren at Giza*), Wiesbaden, 1970. These fragments are in the Egyptian Museum in Cairo.

Figures 3.3 and 3.4 show the engraving published in this report in the *Quarterly Review*, done from a drawing by Henry Salt (or someone commissioned by him), and sent by him to London for reproduction. It shows the layout of the altar and place of worship that existed between the paws of the Sphinx in Roman

times, as discovered by Caviglia. In the foreground is a "four-horned" altar. But the Romans and the Ptolemies before them had retained as the central feature, at the very back, the great stela of Thutmosis IV with its inscription and its picture of two sphinxes perched on pedestals, to whom the pharaoh is making offerings. The stela is 14 feet high and is carved in granite. The photo I took of this stela, which is still *in situ* at the Sphinx, is in figure 3.8; figure 3.5 is an older black-and-white full photograph. Salt's drawing of it is reproduced in figure 3.7. These should all be compared.

In the year following the *Quarterly Review* account, an account of Caviglia's work in Egypt was published in Scotland in *The Edinburgh Philosophical Journal*, which contained no illustrations but did have these interesting remarks about the Sphinx:

The French savants appear to have done nothing more than uncover the back of this stupendous piece of sculpture; and, if they attempted any other excavations, cannot possibly have proceeded far in their work, as the top of the wall, which has now been discovered, is not above [i.e., not more than] three feet below the level of the sand. Mr. Caviglia . . . proceeded, therefore, to carry on his excavations in the front; and, after labouring for the space of nearly four months, with the assistance of from 60 to 100 persons every day, he succeeded in laying open the whole figure to its base.<sup>3</sup>

Here is the description given in the *Quarterly Review* of the scene as it was when excavated:

On the stone platform in front, and centrally between the outstretched paws of the Sphinx, was found a large block of granite, fourteen foot high, seven broad, and two thick. The face of this stone, which fronted [faced] the east, was highly embellished with sculpture in bas-relief, the subject representing two Sphinxes seated on pedestals, and priests [actually the pharaoh, not priests] holding out offerings, beneath which was a long inscription in hieroglyphics, most beautifully executed; and the whole design was covered at top, and protected, as it were, with the sacred globe, the serpent, and the wings [i.e., a winged solar globe].<sup>4</sup>

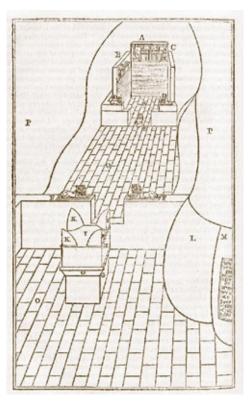

Figure 3.3. This engraving was published in the *Quarterly Review*, London, vol. 19, no. 38, April–July 1818, p. 416, based on a drawing sent from Egypt by Henry Salt. It shows the area between the forelegs of the Sphinx, as excavated by Caviglia the

previous year. All subsequent illustrations of this scene are copies from this one and not always as accurate. This is what the area between the paws of the Sphinx looked like at the time of the Greeks and Romans, when offerings were burned on the altar to the "god," as the Sphinx was conceived at that time. In the foreground of the engraving is the altar with the four "horns." To either side, designated by the letter "P," are the forelegs of the Sphinx. The Dream Stela, marked "A," is at the back, and still stands *in situ*. (The stelae to either side, marked "B" and "C," have been moved to museums.) The large inscription in Greek at far right, on a toe of the Sphinx, is by Arrian; it is described at length in chapter 6, where the text and translation are also given and the importance of this inscription for our ideas of the true nature of the Sphinx are discussed. This entire area was originally of New Kingdom construction, with the focus on the Dream Stela. The area was altered by the Greeks and Romans, and the altar is probably Greek. The purpose of the area was the worship of the Sphinx as the new deity Harmachis. But this had nothing to do with the original nature and purpose of the Sphinx, which had been long forgotten by the time of the New Kingdom. See figure 3.4 (below) for an explanation of each lettered detail in the drawing. One thing to notice about the drawing is that the Dream Stela's text is shown here as intact. As discussed in the main text, this text was indeed intact when found, but the bottom half was destroyed by the local people. Hieroglyphics had not yet been deciphered, so there was no way anyone could read the text before it was half-destroyed. (*Collection of Robert Temple*)

The annexed sketch will convey to the reader the disposition of the ground, and the objects by which it was occupied, in front of the Sphinx and between its paws, in which Is the granite tablet, 14 feet high, 7 feet wide, and 2 feet. B. The side tablet, still standing. The tablet fallen, which has been sent to the British Mu-D. Two small Sphinxes, supposed to have stood in these places, fragments of them having been found near. Statue of a lion, of the best Egyptian sculpture. Two lions of ruder sculpture supposed to stand here, being found near the spot. G. The granite basement of an altar. H. The upper part of the altar-Top of the altar, bearing the marks of burnt sacrifices. K. The horns of the altar, one of which was found in its place. The first digit of the Sphinx's paw. M. The second. The pavement. PP. Parts of the two fore legs of the Sphinx.

Figure 3.4. Key to figure 3.3.

Figure 3.5. A full view of the front of the Dream Stela of Pharaoh Thutmosis (Thothmes) IV. This is plate XL, following page 140, in Selim Hassan's book *The Great Sphinx and Its Secrets*, Cairo, 1953. A drawing of the full stela is reproduced in figure 3.7, which shows more of the text surviving than is visible here; before this photo was taken, some of it fell off and was lost. Originally, when excavated in 1817, the text was complete, but the local people tore half of it away within months.

Figure 3.6. This stereoview taken between 1926 and 1936 shows the Dream Stela beneath the chin of the Sphinx and the altar area with a man standing just behind it. The two stelae that were found to either side of the Dream Stela when Caviglia made his excavations have been removed to museums. (Collection of Robert Temple)

Figure 3.7. This is Henry Salt's drawing from late 1817 of what remained of the text of the Dream Stela of the New Kingdom pharaoh Thutmosis (Thothmes) IV, which was found upright beneath the chest of the Sphinx and between its paws when Caviglia carried out his excavations. This drawing is found in *Operations Carried On at the Pyramids of Gizeh in 1837* by Colonel Howard Vyse and John S. Perring, London, 1842, third appendix volume, plate opposite page 110. (*Collection of Robert Temple*)

Figure 3.8. The Dream Stela of the New Kingdom pharaoh Thutmosis IV (reigned 1411–1397 BC), which he erected between the front paws of the Sphinx to celebrate the dream he had about it and to boast of his clearing and restoration of the monument, which had been buried up to its neck in sand until that time. The pharaoh himself is shown twice, once on the left and once on the right, making offerings to a small sphinx on a pedestal, which is a way of representing the Great Sphinx at the same scale with the king for purposes of the stela. (*Photo by Robert Temple*)

The report did not mention that the great stela had been placed there by Pharaoh Thutmosis IV, nor was the story that the stela told recounted, because, as already noted, at that time no one could read a word of it! Hieroglyphics had not yet been deciphered. It would be another four years before Champollion made his very first translations of hieroglyphics, and we do not know exactly when this stela was finally deciphered and actually read, but it would certainly have been some years later.

Here is the key part of the text of the stela, as we can now read it:

Year I, third month of the first season, day 19, under the Majesty of Horus . . . . the Son of Ra, Thothmes [Thutmosis] IV, Shining in Diadems. . . . When His Majesty was a stripling, like Horus, the Youth in Khemnis, his beauty was like the Protector of His Father [a title of Horus], he seemed like the God himself. The army rejoiced because of love for him [this is very revealing, since the New Kingdom pharaohs tended to be very militaristic]. . . . Behold, he did a thing which gave him pleasure upon the highlands of the Memphite Nome [a Nome is an administrative district, the district being that of Memphis, and its highlands being the Giza Plateau], upon its southern and northern road shooting at a target with copper bolts [arrows], hunting lions and the small game of the desert, coursing in his chariot, his horses being swifter than the wind, together with two of his followers, while not a soul knew it.

Now, when his hour came for giving rest to his followers, it was always at the Setepet (Sanctuary of Hor-em-akhet [Horus-in-the-Horizon]) [the temple built beside the Sphinx by the slightly earlier pharaoh Amenhotep II, the actual Sphinx Temple itself being then unknown and completely buried in sand], beside Seker [the god Sokar] in Rostaw [this refers to what we today call the Valley Temple of Giza] . . . in the desert . . . the Splendid Place of the Beginning of Time. . . . Now, the very great statue of Kheperi [the rising sun, the name that Thothmes here gives to the Sphinx, which faces due east] rests in this place the great in power, the splendid in strength, upon which the shadow of Ra [the sun] tarries. The quarters of Memphis, and all the cities which are by him come to him, raising their hands for him in praise to his face, bearing oblations for his Ka [his animating principle, one of the Egyptian categories of "spirit"].

One of those days it came to pass that the King's [younger] son Thothmes [who was not heir to the throne] came, coursing [hunting on horseback] at the time of mid-day, and he rested in the shadow of this Great God. Sleep seized him at the hour when the sun was at its zenith [noon], and he found the Majesty of this Revered God speaking with his own mouth, as a father speaks with his son, saying: "Behold thou me, my son, Thothmes. I am thy father, Hor-em-akhet-Kheperi-Ra-Atum [Horus-in-the-Horizon—Rising Sun—Sun God—Creator God]; I will give to thee my Kingdom upon earth at the head of the living [i.e., make you the pharaoh]. Thou shalt wear the White Crown and the Red Crown [the two crowns indicating the pharaoh] upon the Throne of Geb [the god of the Earth; this was the customary phrase to describe the pharaoh's throne], the Hereditary Prince. The land shall be thine, in its length and in its breadth, that which the eye of the All-Lord shines upon. The food of the Two Lands [Upper and Lower Egypt] shall be thine, the great tribute of all countries, the duration of a long period of years. My face is directed to you, my heart is to you; Thou shalt be to me the protector of my affairs, because Iam ailing in all my limbs. The sands of the Sanctuary, upon which I am, have reached me; turn to me in order to do what I desire. I know that thou art my son, my protector; behold; I am with thee, I am thy leader."

When he had finished this speech, the King's Son awoke, hearing this . . . [some lost text] . . . he understood the words of the God, he put them in his heart.  $\frac{5}{2}$ 

This stela is now called by archaeologists the Dream Stela because it bears the inscription recording the pharaoh's dream.

Only after the Dream Stela had been excavated and deciphered did we know the story about the younger son of the king falling asleep at noon in the shade of the Sphinx with his two riding companions and having the dream that if he cleared the Sphinx of sand and paid it honor, it would make him king of Egypt. This story was otherwise unknown. And yet in AD 1482 it was still remembered from ancient times by the local inhabitants of Giza and told to a Dutchman!

As far as I know, this is the only conclusively proven example of an accurate continuity of oral tradition over such a fantastic amount of time. It belongs in the *Guinness Book of Records*.

Since we have had this conclusive and unexpected proof of the validity of some Giza folklore over an otherwise quite unbelievable period of time, we must take the Giza folklore as a whole much more seriously than we would otherwise be inclined to do. We must therefore examine some other claims about the Sphinx that the locals have recounted for centuries, to the amusement of visitors, who have mostly thought it was all fairy tales told to the tourists.

In part 2 of this book I have gathered a massive number of early travelers' accounts of the Sphinx, and anyone who reads through them will see several constantly recurring themes. I intend to examine several of these. But let us start with one that seems to be the most ridiculous of all: the absolute insistence by the locals that there is a direct connection between the Sphinx and the Pyramid of Chephren. Usually this takes the form of insisting that there is an underground tunnel leading from one to the other. Sometimes this tradition varies, and the underground tunnel is said to come out in the well shaft of the Great Pyramid, but that seems to be a variant tale concocted by speculation and the desire to impress European visitors when they began to go down the well shaft. After all, no opening to the Pyramid of Chephren was known until Belzoni found it early in the nineteenth century. So it was difficult when Europeans kept crawling in on their hands and knees over the mounds of sand and bat dung to explore the interior of the Great Pyramid and forcing terrified Arabs to hold ropes while they descended the well shaft, from which hordes of huge bats emerged and where candles and lamps went out, to continue to insist that the connection between the

Sphinx and the Pyramid of Chephren was so important. It was far easier to speculate that the Great Pyramid's well shaft was the point of connection. And yet there are sufficient occasions when the locals insisted on the connection with the Pyramid of Chephren, into which curious Europeans could not enter, to make it clear that this was the original tradition.

Figure 3.9. A late-nineteenth-century photo of the Giza Plateau looking northwest, when the famous centuries-old sycamore tree was still standing, and some palms as well. In the background is the Great Pyramid, and to the right of the sycamore the head of the Sphinx protrudes from the sand in the distance. At this time, there were no tourists, and things were much quieter. This is very much what the Giza Plateau must have been like during the New Kingdom, when the future king Thutmosis IV (who reigned 1425–1417 BC) went hunting on the plateau and fell asleep in the shade of the Sphinx's head and had his famous dream, which he inscribed upon the Dream Stela that still stands between the paws of the Sphinx. The serene timelessness of the Giza Plateau only really ceased after the Second World War, when the international tourist plague commenced. (*Collection of Robert Temple*)

So when I say that I have recently confirmed this folklore tale, the reader may well think that I am claiming to have crawled along a tunnel for the whole distance. But nothing of the kind! In the finest ancient Egyptian tradition, the connection that existed was of a subtle and esoteric nature that until now no one has ever suspected. The locals had obviously been told far in the distant past that such a connection existed, but not understanding its true nature, they assumed that underground tunnels were the answer. This seemed logical, especially since there were plenty of tunnels at the Sphinx that the locals could well imagine once went much farther into the plateau; they also knew that the plateau was riddled with shafts and tombs, and it was by no means illogical of them to presume that anyone who could build something the size of a pyramid could easily dig a tunnel as far as the Sphinx.

To describe the strange connection between the Sphinx and the Pyramid of Chephren I have to refer readers to my earlier book *The Crystal Sun.* In color plate 30 of that book, the reader will see a photo of one of my major discoveries at the Giza Plateau. (I have also reproduced this photo on this book's website, www. sphinxmystery.info.) It is the winter solstice sunset shadow that I discovered cast on the south face of the Great Pyramid by the adjoining Pyramid of Chephren. It had been there once a year for at least 3,500 years but no one had "seen" it until I spotted it in 1998. (It was actually not visible in 2000 because of hazy atmospheric conditions.) I noticed that this shadow had a significant slope. I measured it and discovered that the slope was identical with the slope of the Ascending and Descending Passages inside the same structure. It was therefore a hint on the outside of what was on the inside of the Great Pyramid, but only someone who already knew about such things could ever "see" it. After all, if you didn't know there were passages inside and didn't know their slope, how could you possibly know the

significance of the slope of the shadow? If you were an Egyptian architect of the Old Kingdom, you would know the angle, but ordinary folk knew nothing of this. The Egyptians seem to have enjoyed such inside jokes.

Since the publication of *The Crystal Sun*, I have purchased an old photo of the Sphinx with the Great Pyramid in the background, which is reproduced in figure 3.9. This unusual photo, never before published, gives a striking image of the pyramid shadow, though it had not yet risen to its full height (or had declined from it). The photo was obviously taken several days either before or after the actual day of the winter solstice. It is only at the solstice that the shadow achieves the angle that I mentioned. However, this is the only other photo showing the sunset shadow at that time of year that I have ever seen, so I publish it here for the first time. I bought this photo with only the information written on the back that it was taken in 1941 by Frank Freeman, with no explanation as to who Frank Freeman might possibly be. I have done an Internet search, and it is possible that he might have been Professor Frank Nugent Freeman (1880–1961), who was dean of the School of Education at the University of California at Berkeley, and whose hobby was photography. However, I bought the photo in Britain, so it is more likely that it was another man. Maybe we will never know who he was. The shadow is cast on the south face of the Great Pyramid by the adjoining Pyramid of Chephren only at sunset near the time of the winter solstice, and the shadow reaches its culmination on that day, when it has the "golden angle," the same angle as the slopes of the Ascending and Descending Passages inside the Great Pyramid. When I use the expression "golden angle" in this book and elsewhere, I invariably mean the angle of 26° 33′ 54″, and not the angle of 137° 30' 27", a related but more complicated angle derived from a formula (360 divided by phi squared) to which the name "golden angle" is sometimes applied by certain modern mathematicians. It is unfortunate that there are two angles competing now for the name "the golden angle." As "the golden angle" figures prominently in chapters 7 and 8, it is essential that readers be aware of which angle I mean.

Figure 3.10. This remarkable photo taken in 1941 shows the sunset shadow on the south face of the Great Pyramid, which is cast by the adjoining Pyramid of Chephren. This photo was not taken precisely on the day of the solstice, so the shadow has either not yet culminated or is now in decline (depending on whether this photo was taken before or after the solstice, a detail we do not know), but on the evening of the solstice the shadow becomes the Winter Solstice Sunset Shadow. At that time, its acute angle at the southwest corner of the pyramid measures the same as the angle of slope of both the Ascending and Descending Passages inside the Great Pyramid, a unique angle known as "the golden angle." This was a secret visual code of the Egyptian priests, showing on the outside what was on the inside. The slope of the ascending passage rising out of the Valley Temple beside the Sphinx has the same angle. As for the golden angle of the shadow, it is part of the huge multi-golden-angled complex of the Golden Giza Plan depicted in figure 7.25 and explained at length in chapter 7, pages 366–71. (*Photo by Frank Freeman*)

Color plate 31 in *The Crystal Sun* is a photo I took relating to another of my discoveries at Giza. The huge megalithic structure near the Sphinx that we call today the Valley Temple has a narrow sloping

passageway leading upward from the interior of the temple and out of the back onto the Chephren Causeway. We can call it the ascending passage of the Valley Temple, since it is on a slope. Of course, if you go back inside, the ascending passage becomes a descending passage, because you have turned around. But there is no doubt that the significance of the passage in terms of cult and ritual was to lead up and out onto the plateau of the sacred necropolis, so ascension was its motif, being also to the Egyptians a metaphor for resurrection. As I describe in *The Crystal Sun*, chapter 9, where I talk about all these things, I measured the slope of this ascending passage, something no one else had ever thought to do. I discovered that it had the same slope as the Ascending Passage and the Descending Passage inside the Great Pyramid, and also of course of the winter solstice sunset shadow on the Great Pyramid. The slope is 26 degrees, 33 minutes, and 54 seconds. It is what I have called the "golden slope." Surely there must be some significance to all this?

Indeed there is. As I explain at some length in *The Crystal Sun*, this particular angle, which we can call the "golden angle," is the precise value of the acute angle of a right-angled "golden triangle" that embodies the golden mean proportion (the ratio of 1 to 1.618). The Danish art historian Else Kielland established with conclusive and absolutely overwhelming evidence and analysis that this angle was the basis for all Egyptian art and architecture. She did this in her monumental work *Geometry in Egyptian Art* (Copenhagen, 1955). Figure 55 in *The Crystal Sun* is taken from her book and demonstrates some of her evidence. Figure 8.2 here is reproduced to help elucidate her ideas. These matters are discussed further in chapter 7.

The King's Chamber inside the Great Pyramid embodies no fewer than eight occurrences of the golden angle, and the coffer in the chamber embodies yet more. Figure 54 in *The Crystal Sun* shows the use of the golden angle and the golden triangle to define the Grand Gallery. I also explain in *The Crystal Sun* that the solstice shadow on the Great Pyramid is truncated by the line running up the middle of the face (which in geometry is called the apothegm); this cuts it at exactly the right point to form a golden triangle, just as the commencement of the Grand Gallery on the inside of the same structure cuts the slope of the Ascending Passage at just the point to make a golden triangle. I also show, in plate 65 of *The Crystal Sun*, the aerial photo that proves that the apothegm of the southern face of the Great Pyramid is marked by a slight indentation made on purpose during the construction that is invisible to the naked eye on the ground and can be seen only from the air. The "formation" of the golden triangle by the solstice shadow could thus be known only by the gods and by the architects.

But we must not go any further into these matters, which I have already discussed at length in another book. My purpose for introducing the material here briefly is to explain my discovery that relates to the Sphinx's connection with the Pyramid of Chephren. On this book's website, <a href="www.sphinxmystery.info">www.sphinxmystery.info</a>, I reproduce some of the relevant illustrations from *The Crystal Sun*, as that book is now out of print.

In January 2001 I was allowed access to the Sphinx Temple (the largely ruined structure directly in front of the Sphinx) for the purpose of an archaeological investigation approved by the Egyptian Supreme Council of Antiquities. Normally the Sphinx Temple is kept locked, and few archaeologists have occasion or permission to enter it. It is never entered by tourists.

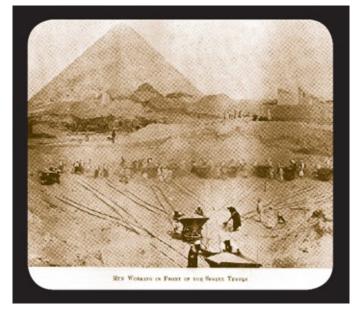

Figure 3.11. A photo from 1936 showing the clearing of the Sphinx Temple from beneath the sand by Selim Hassan. This is plate 32 following page 68 in Hassan's *The Great Sphinx and Its Secrets*, Cairo, 1953. This was the first time the temple had been seen for nearly four thousand years, since circa 2000 BC.

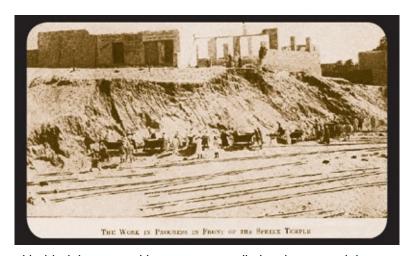

Figure 3.12. The mountain of sand behind the men with wagons on rails is what was sitting on top of the Sphinx Temple in 1936, when this clearance by Selim Hassan was undertaken. On top of that sand mountain was, as we can see here, a number of modern tourist shops catering to the visitors to the Sphinx. They all had to be demolished before the sand could be removed from underneath them. This caused an enormous amount of local resentment, as many people lost their livelihoods and businesses. Only after all this was cleared away was it revealed that an entire lost temple lay beneath the buildings and the sand, the Sphinx Temple as we now call it. This photo is plate XXXI, opposite page 68, in Selim Hassan's book *The Great Sphinx and Its Secrets*, Cairo, 1953.

Because I was allowed into the Sphinx Temple and spent considerable time there, I was able to notice many details that are not immediately obvious even to someone fortunate enough to gain access. Most people managing to gain special access would be allowed a quick look-round and then be ushered out again. But I had to linger due to the nature of my work. The floor of the Sphinx Temple may once have been covered with some fine substance. Selim Hassan thinks the floor was once of alabaster, and speaks of "the fine alabaster which paved its magnificent court." There are still large chunks of raw alabaster sitting around inside the temple, which I found rather peculiar, and for which there appears to be no obvious explanation. Egyptian alabaster is different from European alabaster; the former is calcium carbonate, whereas the latter is calcium sulfate. The true mineralogical name of Egyptian alabaster is travertine, and it is a form of limestone. However, the floor of the Sphinx Temple now consists simply of leveled bedrock. My detailed accounts of the Valley Temple and Sphinx Temple may be found in *Egyptian Dawn*, where I also explain the significance of the chunks of raw alabaster.

Figure 6.17 is a photo I took of the view of the Sphinx and the Pyramid of Chephren from the floor of the Sphinx Temple. As I gazed at the Pyramid of Chephren from inside the Sphinx Temple, I was suddenly struck by an idea. I took a device called an inclinometer, which we had with us, and took a sighting of the apex of the Pyramid of Chephren. I was able to confirm my hunch: the floor of the Sphinx Temple had been lowered into the bedrock to just the right depth for a sightline from there to the tip of the pyramid to form the golden angle. This angular relationship is shown in figure 3.12. A view of the Sphinx from the top of the Pyramid of Chephren is shown in the photo reproduced as figure 3.14, which was published in 1910.

This means that the slope of the sight line leading upward through the air from the floor of the Sphinx Temple to the apex of the Pyramid of Chephren matches the slope of the ascending passage leading up out of the Valley Temple next door in the same direction, and it forms a golden angle in three-dimensional space! Surely this is an example of the Egyptians carrying their surveying and design planning to extraordinary lengths!

I believe this is the true "direct connection" between the Sphinx and the Pyramid of Chephren. The locals have always known there was one, but they never understood its true nature even in ancient times. And since the Sphinx Temple was buried in sand and totally unknown during the New Kingdom, the vague tradition of this "connection" must go back to Old Kingdom times, which means a survival in folklore for about a third longer than the survival of the story of Thutmosis IV, or an additional thousand years.

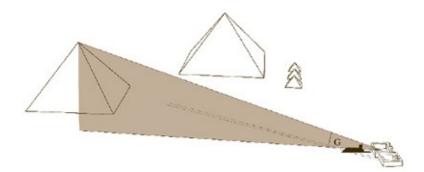

Figure 3.13. A drawing looking northward, showing the Sphinx at right and in front of it the Sphinx Temple, beside which in the foreground is the Valley Temple. In the background are the Great Pyramid and its three mini-pyramids. At the left we see the Pyramid of Chephren. The shaded area is an artist's attempt to show the aerial golden angle that I measured with an inclinometer from the floor of the Sphinx Temple when I took a sighting of the tip of the Pyramid of Chephren. This drawing is not strictly accurate or to scale and is intended to be merely suggestive. The letter *G* represents "golden angle," as the acute angle of the aerial triangle is a golden angle, and this must have been intentional. The shaded area is shown as going below ground level, because the base of the triangle must be taken to be the horizontal surface of the floor of the Sphinx Temple, not the much higher level of the plateau surface beside the pyramid. (*Drawing by Daud Sutton*)

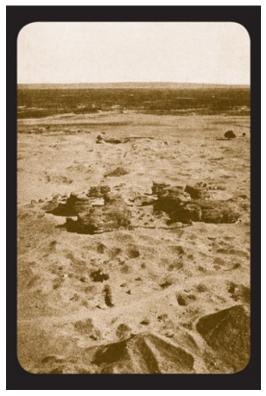

Figure 3.14. This photo, taken by Uvo Hölscher about 1900, was published in 1912. He was standing on top of the Pyramid of Chephren, looking due east. The Chephren Causeway is entirely covered with sand and invisible. The large unexcavated ruin in the foreground is the Funerary Temple of Chephren, which today is fully excavated, and which contains gigantic blocks of stone, some of them weighing more than fifty tons each. Beyond it, slightly to the left of the center of the photo, the head of the Sphinx protrudes from the sand. The Sphinx Temple, still unknown, is entirely buried in a huge mound of sand in front of the Sphinx at this time. The Valley Temple, known and partially excavated, but not yet excavated by Hölscher, is in front of the Sphinx and slightly to the right. The top of it may be seen, but little more, as a dark line protruding from the sand. In the distance, the floodplain of the River Nile extends toward Cairo. In ancient times, the river came right up to the foot of the Sphinx. To the right of the Sphinx, at the edge of the photo, is the huge old sycamore tree that may be seen in the foreground of figure 3.9 taken some decades earlier. This photo was published by Uvo Hölscher in his excavation report of the Valley Temple: Uvo Hölscher, Das Grabdenkmal des Königs Chephren (The Funerary Monument of King Chephren), vol. 1 of Veröffentlichungen der Ernst von Sieglin-Expedition (Publications of the Ernst von Sieglin Expedition in Egypt), edited by Georg Steindorff, containing also contributions by Ludwig Borchardt and Georg Steindorff, J. C. Hinrich's Booksellers, Leipzig, 1912. This view is looking downward toward the golden angle of the acute angle made at the point below the sand in front of the Sphinx in this photo (i.e., the floor of the Sphinx Temple, which was still unknown and was unexcavated at the date of this photo). Because it is so difficult to get to the top of the Pyramid of Chephren, I know of no other photo like this one in existence.

Another point to be made is that the hypotenuse (the longest side, which is always opposite the right angle) of a sacred triangle was known in Egypt as "Horus," a fact recorded by Plutarch in his treatise *On Isis and Osiris*. (I have discussed this in *The Crystal Sun*, and I discuss it further in chapters 7 and 8 here.) The sight-line leading from the Sphinx Temple to the top of the Pyramid of Chephren was a hypotenuse, and thus a Horus. This could explain why the name Horus was so often associated with the Sphinx even though the Sphinx was not always *identified as* Horus. Also, no other monument in Egypt was called "Horus-in-the-Horizon." But if we consider the geometrical relationship that I have discovered, we realize that if we were to stand on top of the Pyramid of Chephren and look down the sightline, it would disappear into the horizon, and the sightline itself would thus literally be a Horus-in-the-Horizon. I was pleased when I discovered this fact, because I had never accepted the other explanations that various authors had suggested for the meaning and origin of this strange name as applied to the Sphinx.

Now we see even more reason to take the Giza folklore seriously. The folklore is also full of insistence on secret openings, doors, tunnels, and so forth in and around the Sphinx, and insistent also on the Sphinx's use as an oracle with a voice issuing apparently from its mouth. I have already pointed out in

chapters 1 and 2 how many openings, doors, tunnels, and so forth are really to be found at the Sphinx, even though most have been sealed off. In part 2 there are numerous accounts of these from early European travelers. We will have more to say about them later. Even when Caviglia was excavating the Sphinx, as we are told in the *Quarterly Review*, "The Arabs . . . told Mr. Caviglia, that the French had discovered a door in the breast of the Sphinx [in 1798, nineteen years before Caviglia's excavations], which opened into its body, and passed through it to the second pyramid." All these things will be discussed further later on and relate also to the section containing the early travelers' accounts.

But let us turn now to another strange feature of the local folklore account of the story of Thutmosis IV, which I did not quote at the beginning of this chapter and have reserved until now. This is the remainder of van Ghistele's account of what the locals told him about that pharaoh, whose name they no longer remembered: "A little while after his coronation he [the new king] returned to the place where the head [the Sphinx] was, which he decapitated with an axe, saying: 'It's all very well that you have given me counsel so that I can secure Egypt; but from today on, you will not give any more counsel to anyone.' And it is thus that since then the head rests upon the ground up until our own time."

The first thing I want to point out about this part of the tale is that another small detail relating to Thutmosis IV is known to be accurate, namely the passage that says that he returned to the Sphinx "a little while after his coronation." In fact, the Dream Stela is dated in the first year of his reign, whereas one would not normally expect such a prompt tribute. A normal king would get around to it later. So this too reflects an accurate tradition.

But what are we to make of the strange tale, rather amusing in fact, that Thutmosis chopped off the head of the Sphinx and that is why it lies upon the sand? The last part of that is obviously a joke, since all the local accounts of the Sphinx agree that the Sphinx has a buried body, and this account itself states only a few sentences earlier that the Sphinx pleaded with Thutmosis to be cleared from the sand. None of the locals *really believed* that the head of the Sphinx was detached and "lay upon the sand." It was a witticism. But what clearly *was* believed was that the head had somehow been "decapitated" even though it obviously had not really been severed. And although the mutilation of the nose by the fanatical Muslim Sheikh Mohammed had already taken place, this cannot be what the locals were referring to. So what does this strange story really mean?

Figure 3.15. The immense body of the Sphinx has a tiny head that is out of proportion and has been recarved from a much larger head. At right, the rear of the Sphinx Pit shows the horizontal water level that was the general level during the time of its use as a Sphinx Moat. (*Photo by Robert Temple*)

I believe that this tale relates to the recarving of the face of the Sphinx, an action that was of such

drastic extent that the Sphinx was effectively decapitated and a face shaped out of a kind of stump. That the head of the Sphinx as we know it today, and as it has been known for many centuries, is far too tiny for the gigantic body has been remarked on by many people. This can be seen easily in figure 3.15 above and figures 4.1 and 4.2. Many people, including some Egyptologists, have suggested that the head was substantially cut down in size and recarved in the image of a pharaoh. What we have not known until now is *which* pharaoh, and when it happened. In the next chapter I answer these questions. It was not Thutmosis but an earlier pharaoh, and I have been able to identify him.

During the New Kingdom, the era of Thutmosis, the Sphinx was honored by a succession of pharaohs, including several before him, and the statue became an object of veneration to which offerings were made (another accurate detail of the folklore). It was apparently during that period that a pharaoh's beard of stone was carved and somehow affixed to the Sphinx's face. See figures 3.16 and 3.17 for evidence of holes bored into the face, to which the beard must have been affixed. As already mentioned, these holes were found in excavations in the nineteenth century, and part of the beard is in Cairo (fragments that were smashed in the museum, so that only some now remains of what was originally excavated) and part is in London. But this beard was most definitely not an original feature of the Sphinx. It was probably also at this time that the conical hole was bored in the top of the head of the Sphinx and used for the insertion of a pole to support an elaborate headdress. Selim Hassan was proud about filling up this hole in the 1930s: "A hole that existed in the head of the statue was also filled in." This hole was 9 feet deep, with stones at the bottom so that its true depth was never determined, as several of the travelers' accounts in part 2 make clear. Some ill-informed people thought this hole might have been drilled by Howard-Vyse in the nineteenth century, but they are wrong. It was ancient, though probably not original. Pictures of the Sphinx shown on New Kingdom stelae show it with a headdress. An example may be seen in figure 3.18. It is generally also shown with its beard. In other words, the Sphinx was considerably "tarted up," as the British expression goes. It may also have had an ornamental collar thrown around its neck, since some representations show one. And it may have been at this time that the entire statue was painted with a red face and a yellow body. It was only in the twentieth century that the last vestiges of red paint vanished from the surface of the Sphinx's face. Many of the travelers' accounts in part 2 describe the red and yellow color of the Sphinx, and by the nineteenth century these accounts speak of traces of it being preserved here and there on the statue.

Figure 3.16. Beneath the left ear of the Sphinx are these two holes, doubtless drilled either during the Middle Kingdom when the face was recarved or during the New Kingdom, at whichever time the Sphinx's beard was affixed. (*Photo by Robert Temple*)

Figure 3.17. Here, the angle of the light enables us to see clearly the holes beneath the right ear of the Sphinx where the beard was affixed in later times. The modern concrete of the 1930s used as an extension of the side lappets of the *nemes* headdress is also clearly visible here, as is the way the bottoms of the stone portions of those lappets were chipped away to be level for the affixing of the modern concrete. (*Photo by Robert Temple*)

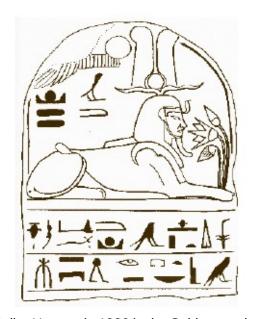

Figure 3.18. This stela was excavated by Selim Hassan in 1936 in the Sphinx precinct. This particular stela dates from the reign of King Thutmosis (Thothmes) IV, the pharaoh who cleared the Sphinx of sand and erected the Dream Stela. The solar disk is shown between two feathers of Maat arising from two ram's horns in the Sphinx's headdress. He is smelling three large blue lotus flowers (a symbolic flower; its delicate scent was meant to bestow immortal life). A solar disk with a single wing is seen floating in the air to the left of the headdress, which enables us to date the stela, as this was a short-lived design fashion. The hieroglyphic text below the picture says: "A boon that the King gives, and Hor-em-akhet [Horusin-the-Horizon, the name given to the Sphinx in the New Kingdom]; (that they may) give him a sweet heart (i.e., contentment) in every place. Made by Inhermes." (Selim Hassan, *Sphinx*, pp. 136–37, figure 32. It is figure 32 also in *Le Sphinx*, opposite p. 86.)

Left: Figure 3.19. This stela, excavated at the Sphinx in 1936 by Selim Hassan, depicts Horus-inthe-Horizon in falcon form. Horus-in-the-Horizon became a name for the Sphinx itself in New Kingdom times, but originally, Horus-in-the-Horizon was the name of the rising sun, who was the revivified and resurrected Osiris, reborn at sunrise in the form of his own son Horus, especially at Giza (for a full account of this mythology and its relevance to Giza, see chapters 7 and 8).

Right: Figure 3.20. A photo of the stela shown in the drawing in figure 3.19, which portrays Horus-in-the-Horizon as a falcon.

Several crude pictures of the Sphinx, of New Kingdom date and later, are reproduced in figures 3.21 to 3.23. These depictions were all found carved onto stelae erected in the Sphinx precinct and excavated there between 1817 and 1937. They all show the Sphinx with a beard, all but one of them with the beard clearly held on by a strap to a point below the ear where bored holes may be seen in figures 3.16 and 3.17. All but one show the Sphinx with a fancy headdress protruding from the point where the bored hole in the head is. Since the headdress varies, it may well be that the headdresses were interchangeable, different ones being set upon the Sphinx's head at different times as occasion required. All the depictions also show the Sphinx with a royal uraeus serpent on its brow. One of the depictions (figure 3.21) even shows two pyramids crudely sketched in the background. Since the view is taken from the south, and there is only one pyramid behind the Sphinx from that direction (the Great Pyramid), the two pyramids were clearly meant to be suggestive rather than accurate; they are in any case far too pointed. Not all these pictures of the Sphinx are really meant to represent the one at Giza, because three of them are clearly miniature models of it. But they give the idea, and despite their obvious inaccuracies, we are probably safe in assuming that the beard and headdress(es) were definitely attached to the Sphinx from the time of the New Kingdom until the Persian Conquest in 525 BC, when they may have been torn down.

Figure 3.21. A stela excavated by Selim Hassan in 1936 within the Sphinx Moat. Behind the Sphinx at the top, the pyramids of Giza are represented symbolically (there is no attempt at accuracy, as only the Great Pyramid is in that direction). This is the only known ancient representation of the Sphinx in association with a pyramid or pyramids. This is figure 12 opposite page 58 in Selim Hassan's *The Sphinx: Its History in the Light of Recent Excavations*, Cairo, 1949. The text in front of the Sphinx says: "Hor-emakhet [Horusin-the-Horizon], the Twice-great God, the Lord of Heaven." Underneath, it says: "Made by the clever scribe, Mentuher." Two figures are then shown in adoration of the Sphinx, and the text between them reads: "Made by the scribe KaMut-Nekhteu, Justified." The stela was presumably erected at the expense of the two scribes who visited the Sphinx together. The stela probably dates from the New Kingdom. The falcon flying in front of the Sphinx's face is carrying the hieroglyph for "infinity" in his talons, representing Horus as a deity promising eternal life.

Figure 3.22. Selim Hassan excavated this stela in the Sphinx Precinct in 1936. This stela was offered to the Sphinx, under the

names of Hul and Hul-Atum, by a foreign visitor named Tutuya. The colors are well preserved on this stela, and the foreigner's hair is still shown as bright red. The foreigner is probably a Canaanite, who has chosen to call the Sphinx "Hul" after the Canaanite god Huron. The stela is believed to date from either the Eighteenth or Nineteenth Dynasty. The Sphinx's headdress here is the white Crown of the South. On the offering table in front of the Sphinx are depicted the conventional offerings to a deity. The Sphinx wears a huge decorative collar. (Hassan, *Sphinx*, pp. 151–52, figure 35. It is also figure 35 in *Le Sphinx*, opposite p. 97.)

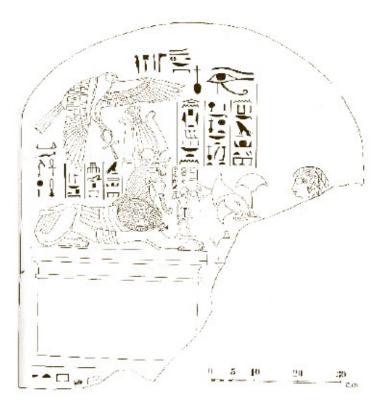

Figure 3.23. This stela was excavated by Selim Hassan in 1936 in the Sphinx Precinct. It is dedicated to the Sphinx by an Egyptian prince named Amen-em-Apt, who was a son of King Amenhotep II. He was also the older brother of the later king Thutmosis (Thothmes) IV, who is suspected of having murdered him and of having erased the older brother's name from this stela (though not in all places, so it can still be read). (Selim Hassan, *Sphinx*, pp. 186–97, figure 39. It is also figure 39 in *Le Sphinx*, opposite p. 108.)

Approaching the Sphinx during the New Kingdom, when people like Thutmosis IV were honoring it, one would have seen a very gaudy and unsubtle statue indeed. It would have had a feather on its head at least, if not a wild and waving headdress; a false beard; and probably a bright, thick bejeweled collar round its neck. And its face would have been painted a bilious red that probably resembled the bad makeup of a contemporary streetwalker. Taste had degenerated somewhat during the New Kingdom, when the pharaohs were what I call "the smiting pharaohs," so often shown smiting their enemies, of whom they had plenty. Gone were the calm, tasteful days of the Old Kingdom, when art was more subtle. The geometrical canon was still observed in the New Kingdom, because it was the sacred tradition. But when it came to coloring and showiness, there were often lapses of taste into what can only be called vulgarity. And, frankly, sticking a feather or a crown on the head of the Sphinx can only be described as *frightfully* vulgar.

The last excavator of the Sphinx Temple was the German archaeologist Herbert Ricke, who published his report in 1970.<sup>9</sup>

Now to return to the story of Thutmosis IV decapitating the Sphinx. I believe that the cutting off of the original head and its recarving as a pharaoh's head did indeed take place at some time, and that the story refers to that action. But I am convinced that the recarving of the head of the Sphinx dates from long before the time of Thutmosis IV and was done by a much earlier pharaoh. The story of Thutmosis doing this was thus probably an example of conflation of tradition, where the pharaoh who in popular

consciousness was most closely associated with the Sphinx became conflated with the earlier pharaoh who recarved the face (even though the actual names of these two pharaohs were no longer remembered). A lot of discussion has taken place among Egyptologists about the date when the particular type of *nemes* headdress represented on the Sphinx was actually worn by historical pharaohs. Ludwig Borchardt in the nineteenth century was insistent that the date of the headdress and the eye stripes were from the Twelfth Dynasty of the Middle Kingdom, indeed from the precise reign of Pharaoh Ammenemes III (1929–1895 BC). This opinion was ridiculed by various subsequent writers, who pointed out that his argument could not be substantiated from existing statuary and that Borchardt had manipulated various inconvenient facts to accord with his theory.

For instance, Selim Hassan accuses Borchardt of "an astonishing flight of fancy," adding for good measure (as partially quoted earlier):

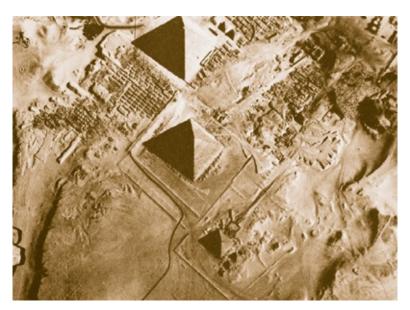

Figure 3.24. The three pyramids of Giza seen from the air, with the Sphinx near the top right corner to the left of the end of the long causeway. From top downward, the pyramids are: the Great Pyramid, the Pyramid of Chephren, and the Pyramid of Mycerinus. This uncredited photo was reproduced by Herbert Ricke as half of the frontispiece to his book, *Der Harmachistempel des Chefren in Giseh (The Temple of Harmachis at Giza)*, Wiesbaden, 1972. Ricke reexcavated the Sphinx Temple and decided to call it the Harmachis Temple, which no one else does. His choice of name was most inappropriate because Harmachis, the name given in later times to the Sphinx, was an unknown deity at the time the Sphinx Temple was last visible and in use prior to 2000 BC.

It seems to me that Borchardt had gone to a great deal of trouble to prove a theory that is altogether wrong from the beginning to the end; that is if he is not having a joke with the scientific world, and indulging in a little "legpulling" at our expense. Note how he refers to the Sphinx in the feminine gender, and at the same time passes observations upon its beard, and identifies it with the King!

If Borchardt was really serious about this article, then I think that of all the theories that he ever put into writing, he must have bitterly regretted having published this one! 11

I have sat through lectures where Egyptologists have argued about whether the *nemes* headdress of the Sphinx dated from the reign of Cheops or only of Chephren in the Old Kingdom. However, I do not believe that the present face of the Sphinx dates from the Old Kingdom at all. In the next chapter, I shall give the evidence that I believe demonstrates the true date for the face of the Sphinx, and identifies the precise pharaoh whose face it is. This discussion will then answer the question: When was the face "cut down" and recarved? But this evidence alone does not answer the question: What was it cut down *from*? Or, in other words, what was the head of the Sphinx before the particular pharaoh had his own face

carved on the stump, or neck, of the original head?

Most people can probably easily accept that the head of the Sphinx was recarved as the face of a pharaoh. Only some people who are very sensitive and touchy about the Cheops-versus-Chephren argument will get highly excited at this. They have a vested interest in insisting that the entire Sphinx was carved either by Cheops (ca. 2589–2566 BC) or by Chephren (ca. 2588–2533 BC) and are prepared to dispute for hours with one another about which of these two actually did it. The fact that there is only a maximum of fifty-six years' difference between the two alternatives does not matter to them; they are engaged in a dispute, and nothing will calm them. I have already said, and will say here again, that it doesn't matter a bit which of the two pharaohs one chooses for having constructed the original Sphinx, as they are so close together. But any student of human disputes will have noticed that what most enrage and envenom people who are arguing with one another are often *small differences*. For some reason to do with human evolution, there seems to be some survival advantage for groups in the fact that small differences are often blown up out of all proportion, which explains why racism is so common, and why skin color (literally a superficial subject) arouses such passions. I suppose that this aspect of animal behavior so commonly seen in humans must have to do with breeding and survival of traits in species. But I prefer to take no part in it.

People who are worried about Cheops versus Chephren will certainly not want to have the interference to their dispute of the suggestion that the face of the Sphinx, which according to them was carved by either Cheops or Chephren (which is what they are disputing), could have been recarved. This would throw their whole argument out of kilter. They can't have that!

In my opinion, the Sphinx may be older than Cheops or Chephren. But, as I shall show in the next chapter, the face as it exists now was recarved by another and later pharaoh who can be precisely identified, and who did not live during the Old Kingdom at all.

In the next chapter, therefore, the true identity of the man whose face is on the Sphinx is revealed, together with all the evidence that makes this identification conclusive. Then, in the chapter after that, we shall consider what the original face of the Sphinx may have been before it was carved into the likeness of that particular pharaoh. And this leads us to a new idea of what the Sphinx itself truly represented. In other words, we then begin to approach the real question that should be concerning us: What *is* the Sphinx?

## THE FACE OF THE SPHINX

Every tourist who sees the Sphinx can see that the head is too small for the body. Millions of people every year become aware of this at first glance, and they often remark on the oddity of it. The disproportion of the head to the body is very clearly visible in figures 4.1 and 4.2, where the head appears to be merely a pimple on the vast bulk of the body. It is difficult to get a good photo of the Sphinx that shows this clearly because of the size of the monument and the fact that you cannot get far enough away to get it all into the photo very easily, even with a wide lens. But in figure 3.15 I think I have managed to show this, at the cost of cutting off the paws. Figure 4.1 is also taken from so far away to the north that the disproportion is obvious.

So what are we to make of this problem of the Sphinx's head? The head really does look as if it has been hacked down to a smaller size and recarved out of the stump of a larger neck. Everyone who knows anything whatsoever about Egyptian art and architecture knows that the Egyptians did not customarily build or carve things that were drastically—and in this case, spectacularly—out of proportion. Why go to all the trouble of carving a Sphinx out of the solid rock, sitting prominently as guardian of the Giza Plateau in front of the pyramids, if it is going to look ridiculous because it has a tiny little head on a giant body? Why not carve a smaller body in proportion to the head, if there was only enough stone to make a head that small? That is what one would expect of such careful artists as the Egyptians.

We must remember that this disproportion of the head to the body was not known for a couple of thousand years, from Roman times to the 1930s, because the body was covered with sand and the disproportion could not be seen. So the issue is therefore a modern issue, an issue dating only from 1926. What people in Roman times thought is no longer our concern; in fact, only one Roman account of the Sphinx survives, by Pliny, and the rest are lost. If anybody at that time thought the head was too small, we have no surviving record of it. And there are no surviving Greek accounts at all.

Figure 4.1. This photo of the entire Sphinx taken from the north, looking south, shows the outrageous disproportion of the present head to the body, something that is entirely against the canons and practice of Egyptian art throughout thousands of years of history. It is impossible that any ancient Egyptian would ever have carved an original statue with such a "pimple" head on such a large body. As is shown in figure 5.11, the present head was recarved out of the neck of a larger original head. The present head was recarved with the face of Pharaoh Amenemhet II of the Middle Kingdom, and although his ego cannot have been of modest proportions itself, out of fairness to him we must admit that there is a very good possibility that the original head had been mutilated, leaving only a neck stump, so that all he had to do was "rehabilitate" the monument in his own image. This would perhaps have seemed an act of piety rather than one of megalomania. (And as the history of the world's religions have proved, the two often go hand in hand.) (The photo is figure 26 in Herbert Ricke's book about his excavations of the Sphinx Temple, which he calls the Harmachis Temple: *Der Harmachistempel des Chefren in Giseh, in Beiträge zur Ägyptischen Bauforschung und Altertumskunde*, ed. by Herbert Ricke, Heft 10, Franz Steiner Verlag, Wiesbaden, 1970.)

It doesn't take a lot of imagination to realize that there must have been many megalomaniac pharaohs in Egyptian history, and any number of them would have liked to have his face put onto the Sphinx. The Middle East has had some well-known megalomaniac leaders in our time, and one can easily imagine earlier versions of the same type of person. The notorious Saddam Hussein of Iraq "restored" Babylon with bricks all stamped with his name and erected gigantic portraits of himself on every street corner in Baghdad: imagine what he would have done if he could have got his hands on the Sphinx! We should never lose sight of the fact that many kings, emperors, and pharaohs in the history of the world have been equally unpleasant, and have suffered from megalomania. The opportunities for sticking a pharaoh's face on the Sphinx were many, and it is more than likely, in my opinion, that this is precisely what happened.

Figure 4.2. An aerial photo of the Sphinx and the Great Pyramid taken sometime after 1937, probably during the 1940s. The excavations of Selim Hassan, completed by 1937, are finished in this photo. The modern road up to the Great Pyramid has not

yet been constructed and is still just a dirt track, seen here as a pale stripe winding up the hill to the right of the Sphinx. This photo is taken from the southeast, looking northwest. It is clear from this photo that far more of the ancient Nile quays in front of the Valley and Sphinx Temples were cleared at this time than they are today, for nowadays those in front of the Sphinx Temple are entirely covered over again. This photo gives a very good view of the Chephren Causeway leading up to the top left corner of the photo, where the Pyramid of Chephren is just out of the shot. The disproportionate size of the Sphinx's head is very obvious from above, being far too small for the body. (*Collection of Robert Temple; photographer unknown*)

The question of what the original head of the Sphinx actually was is another matter. Maybe it was an earlier pharaoh, the one who had the Sphinx carved in the first place. Or maybe it was an animal head. Some would say a lion's head. I have an idea about this matter, and I describe it at length in the next chapter, where I suggest it was an animal head and not a pharaoh's head. After all, there is no reason to assume that it had to be an earlier pharaoh's head, since that is a process of reverse reasoning. One cannot logically maintain that because the Sphinx has a pharaoh's head now, it had to have a pharaoh's head before. It could have been anything. Indeed, an animal head is far more logical and reasonable. After all, the human-headed sphinx as a motif in Egyptian art is really something that became popular in the Middle Kingdom only after about 2000 BC and was not a motif of the Old Kingdom, which is the latest possible date when the body of the Sphinx could have been carved, many centuries before the Middle Kingdom began. We must never extrapolate backward and use the criteria of the Middle Kingdom, when human-headed sphinxes became popular, to insist that this must have been the case in the Old Kingdom, when such ideas seem to have been absent.

A small statue of a human-headed sphinx of some kind was found at Abu Ruash, near Giza, and some people have suggested that it might be an Old Kingdom statue, while others have insisted that it is not. (It is shown in figures 4.3, 4.4, 4.5, and 4.6.) This object cannot be dated, since it is merely a statue excavated very long ago, with inadequate excavation reports, somewhere near or on a site that may or may not once have had a pyramid. Its date is just a matter of personal opinion or of guessing, since dating by association cannot be justified in the absence of any real contextual evidence of any kind. It could just as well be a Middle Kingdom statue, or even a New Kingdom one or a Ptolemaic one. It does not constitute evidence because of the impossibility of dating it. And there is no other evidence of humanheaded sphinxes in the Old Kingdom, or Pyramid Age. What is more, this mysterious object from Abu Ruash has a female face, not a male one, and this is well known to be a typical late development in the evolution of the sphinx motif in Egyptian art. This point was noted by the historian of Mediterranean iconography (I suppose one would call him an "iconographer," which is a highly specialized corner of the history of art that impinges on archaeology) André Dessenne, in his book Le Sphinx: Étude *Iconographique* (*The Sphinx: An Iconographic Study*), published in 1957. Dessenne was not an Egyptologist, and Egypt forms only a brief initial portion of his wide-ranging study of the Sphinx motif in the art of many cultures. He surveys the Assyrians, Cypriots, Mitannians, Hittites, Minoans, and Mycenaeans. The Abu Ruash sphinx is the first sphinx that he discusses in his book (the second being the Great Sphinx of Giza), and here is all he says of it:

It is recumbent. Its face, beardless, is painted yellow, which, following the conventions, indicates that it is a woman's head. [Anyone can see that the face is obviously that of a woman; see figures 4.4 and 4.5.] For this reason the features and traits are more feminine and the hair is separated with a middle parting. The headdress has no uraeus.

This sphinx was found during the clearing of Djedefra's pyramid [a gigantic descending tunnel shaft with no roof, at Abu Ruash, where a "pyramid" has often been assumed in an unfinished state, since if it ever existed, it vanished long ago], and for this reason is thought to be contemporaneous to the

pyramid's building. It may have belonged to a queen mother of the 4<sup>th</sup> Dynasty. Djedefra being the predecessor of Khufu [Djedefra was Khufu's (Cheops's) son, so he could not possibly have been the precedessor of his own father, and this shows Dessenne's tenuous grasp of Egyptological matters!] suggests that the sphinx could slightly predate the one at Giza. It is curious that the earliest available evidence for a sphinx presents it with a woman's head. Surely this is pure coincidence. Other than for its head, the sphinx in question presents no major differences with the masculine type, which is the type with which my study is concerned. This makes it difficult to talk about the Abu Ruash Sphinx as a female, since female sphinxes really only appear much later, during the New Kingdom.<sup>2</sup>

Dessenne's lack of logic, and his even more appalling lack of knowledge of the basics of Egyptian chronology, renders most of what he says useless, except for his comment that female sphinxes really begin to appear only during the New Kingdom, a thousand years after the time of Djedefre. Clearly, the fact that Djedefre was the son of Cheops, and not his father, destroys Dessenne's suggestion that the Abu Ruash sphinx could be earlier than the Great Sphinx of Giza; at best, it could be from a subsequent generation. Dessenne is even so naive as to complain about this sphinx being female, because his book is only supposed to be about male sphinxes, which "makes it difficult to talk about." Although we are grateful for Dessenne pointing out how anomalous it is for a female sphinx to appear a thousand years earlier than any other, we can disregard the rest of his opinions. If he cannot get his pharaohs straight, then he cannot be expected to get his sphinxes straight either.

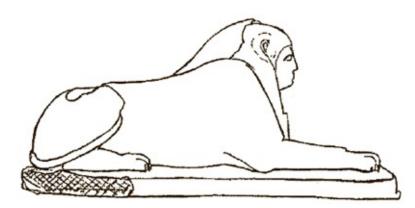

Figure 4.3. This is a drawing of the small limestone statue of a leonine sphinx with a woman's face, which was excavated at Abu Ruash in the nineteenth century and is of unknown date. The body is clearly that of a lion, with a rising massive chest, thick front shoulders, upward-sloping back, and heavy mane. If the Great Sphinx of Giza had been intended to represent a lion's body, it would have looked more like this. This sphinx is also represented in figures 4.4 to 4.6. Since this sphinx is so often mentioned in discussions as possibly being older than the Great Sphinx of Giza, it is important that we be thoroughly familiar with its appearance, for it would therefore constitute conclusive evidence that the Great Sphinx was not a lion. (*Redrawing by Olivia Temple after Bodil Hornemann*, Types of Ancient Egyptian Statuary)

Figure 4.4. The female face of the small leonine sphinx statue excavated at Abu Ruash, date unknown. The headdress resembles that of a modern Muslim woman. (Photo by Bernard V. Bothmer)

Figure 4.5. A profile view of the female face of the small Abu Ruash leonine statue of a sphinx. (Photo by Bernard V. Bothmer)

Figure 4.6. A full view of the small leonine sphinx with a woman's face, carved from limestone, which was excavated at Abu Ruash, date unknown. (Photo by Bernard V. Bothmer)

The Abu Ruash statue bears no relation to the Great Sphinx of Giza, since its body is obviously that of a lion, with huge rising shoulders, a massive chest, and a line to its back in profile that rises at a steep

upward incline toward the head. The Great Sphinx has none of these features, a point that will be discussed in the next chapter. The bizarre female face, wild eyes, and plain headcloth (which suggests nothing to do with royalty whatsoever) are so atypical of Old Kingdom statuary, and the motif of a woman's face on an animal body being otherwise unknown for another thousand years, we must conclude that this strange statue has nothing to do with the Old Kingdom whatsoever. Why it was found sitting around on the high hill of Abu Ruash is a mystery. But Abu Ruash is an inadequately understood site that puzzles everyone. Frankly, I am inclined to believe that this statue is Ptolemaic, an attempt to represent the Greek sphinx (who was a wild and violent female creature) with whom Oedipus had his famous confrontation near the Greek city of Thebes. Possibly there was a Ptolemaic ritual center at Abu Ruash, where this strange object was produced in its late and hybrid style, combining the Greek and Egyptian sphinx legends in one statue. If the female face had been intended to represent a queen, she would never have been shown with no signs of a regal nature whatever, wearing only a head covering that looks very like a modern Islamic hijab. Certainly, the Abu Ruash statue was dismissed in two sentences by the Egyptologist Christiane Zivie-Coche in her book *Sphinx: History of a Monument*, where she says only: "A small limestone sphinx that some consider to be feminine has been attributed to Radjedef [this is the correct form of the name often given as Djedefre], Chephren's predecessor, who was buried at Abu Rawash [Abu Ruash]. Because of its nemes [headdress], a beautiful quartzite head of this king, now in the Louvre, supposedly belonged to a sphinx. These two early examples are not convincing, however, in part because they are not intact, and in part because there are problems with regard to their date." (Zivie-Coche has written these two sentences in rather a confusing way, since the Abu Ruash statue has no nemes headdress, and the *nemes* she is referring to was on a sculpted head supposed to be of Radjedef, which is a completely separate object. It seems truly incredible that just because a detached head with a *nemes* headdress has been found, it is presumed once to have topped a sphinx. The lack of evidence and weakness of the logical inference of whoever made such an assumption—who is not named by Zivie-Coche—is absolutely staggering. This is how false assumptions spread, but it is to the credit of Zivie-Coche that she has rejected them.)

So in this chapter I leave aside for later the question of what was the original head of the Sphinx. What we are concerned with here is: Whose head is on the Sphinx now, and when was it put there?

I believe we can specify exactly whose head is on the Sphinx, and I can give the dates of his reign, so that the question can be answered with complete satisfaction.

Although the Sphinx cannot have been carved later than the Old Kingdom, and indeed it even has some Old Kingdom repair blocks on it, so it must have been carved pretty early, I believe that the head is from the Middle Kingdom.

There are some Egyptologists who strenuously insist that the head of the Sphinx is that of the pharaoh Chephren (Khafre) of the Fourth Dynasty in the Old Kingdom, who reigned approximately 2572–2546 BC. They even try to convince us that the face on the Sphinx resembles that of Chephren, identified statues of whom survive. (Zivie-Coche firmly believes this, as we saw in an earlier chapter.) But it seems to me that any unbiased observer would have to admit that there is no resemblance at all between the two faces. People who say the face on the Sphinx is the face of Chephren are engaging in wishful thinking. They are seeing what they wish to see. Chephren's face is completely different. It is a long, narrow face, which that on the Sphinx is not. The German Egyptologist Rainer Stadelmann has very sensibly denied that the face of the Sphinx is that of Chephren. He says, for instance: "The ears are fundamentally different from those of the statue of Chephren. The ears of the Sphinx are very broad and folded forward, those of Chephren elongated and situated closer to the temples. . . . The overall form of the Sphinx's face is broad, almost

square. On the other hand the features of Chephren were long, noticeably narrower, the chin almost pointed."4

Stadelmann is absolutely correct in these observations. The face cannot be that of Chephren. Anyone who insists that it is might as well say that Tom Cruise looks like Humphrey Bogart. It just "ain't so." See figure 4.7 for a portrait of Chephren, which, if compared with the face of the Sphinx, is clearly of a different person altogether.

So whose does Stadelmann think the face is, then, if not Chephren's? He speculates that it is of his older brother, Pharaoh Cheops (Khufu), who reigned earlier, approximately 2604–2581 BC. But here we have a problem. Whereas several splendid examples of statues of Chephren survive, only one tiny one of Cheops survives. I had a close look at it in the Cairo Museum, and really it is too small and lacking in detail for us to draw many conclusions about it, except that the face is not a long one like that of Chephren. The little ivory statue is only 3 inches high and 1 inch wide. You could easily hold it in the palm of your hand. There is no reason to believe that it is a serious attempt at portraiture. To use this as a basis to claim a likeness to the face on the Sphinx is hopeless. But for what it is worth, what likeness one can make out from this tiny statue also does not look anything at all like the face on the Sphinx. In figure 4.8 are several views of this only surviving likeness of King Cheops.

Figure 4.7. Pharaoh Chephren, with the divine Horus falcon spreading its wings protectively around his head. This is the top portion of the famous larger-than-life-size statue of Chephren in dark gray diorite stone that was found intact in the well of the Valley Temple, having probably been hidden there by priests to save it from destruction when all his other statues in the temple were smashed to pieces by a rioting mob (thought to be during the First Intermediate Period). The statue is one of the most famous things to see in the Egyptian Museum in Cairo. It may readily be seen that Chephren had a long, thin face that in no way resembles that of the Sphinx of Giza. One of the strangest phenomena of modern Egyptology is that many Egyptologists persist in stating that this is the same as the face on the Sphinx. Draw your own conclusions, psychiatrists! (*The Egyptian Museum, Cairo*)

Figure 4.8. Three views of the head of the tiny ivory statue of King Cheops, the only surviving likeness of him. His face is clearly not that on the Great Sphinx of Giza. (*The Egyptian Museum, Cairo*)

Figure 4.9. This was once a likeness carved in relief of King Cheops, but someone in antiquity who evidently hated him chipped out his face, so we don't know what he really looked like. He is wearing the combined Crown of the North and the South.

In other words, all attempts to match the face on the Sphinx to Cheops or Chephren are failures. The face is also not that of any other Fourth Dynasty pharaoh whose likeness has survived. For instance, the face of Mycerinus (Menkaure) is also well known, and the face on the Sphinx certainly is not his either. Nor is it that of Pharaoh Radjedef (Djedefre), another pharaoh of that dynasty whose likeness is well known.

I suggest that the whole Old Kingdom should be forgotten when trying to identify the face, and that the face really comes from the Middle Kingdom, hundreds of years later, when I believe the recarving of the head was carried out.

If this were just a matter of my personal speculation, I would certainly never be writing a chapter about it. I might refer to it in passing, express my opinion, and then move on. But it is precisely because I believe that this identification *can* be justified by considerable evidence of a highly specific kind that I am prepared to make an issue of it.

The identification of the period of the face of the Sphinx was, in my opinion, correctly made in 1897 by the famous German Egyptologist Ludwig Borchardt, whose article on this subject I mentioned earlier. I believe Borchardt correctly identified the dynasty, though not the precise pharaoh, for the face of the Sphinx. By a curious coincidence, Borchardt was a predecessor of Stadelmann's. Both are former directors of the German Institute of Archaeology in Cairo. Borchardt's findings were published in a long-forgotten article in an obscure learned journal, and I do not believe anyone in modern times has ever bothered to read it. It is entitled "Concerning the Age of the Sphinx at Giza." I consider this article so important that I have translated it in its entirety; it appears as appendix 2 of this book.

Borchardt wrote his article long before the Sphinx was cleared of sand, when the disproportion of the head to the body was still unknown. In those days, it was possible to stand higher and have a better and closer look at the Sphinx's head. Today one cannot do that. In fact, it is now almost impossible to see, except from old photos such as those in figures 1.21, 1.43, and 1.44, the necessary details of the top of the Sphinx's headcloth. For it is here that the specific clues as to the date and identity of the face are to be found. But in Borchardt's day, these were very clear and easy to see. One had only to stand there and look straight at them.

Those few Egyptologists who may still be aware of Borchardt's article on the Sphinx would be inclined to dismiss it without a thought, due to the fact that in dating and identifying the face as that of a

particular Middle Kingdom pharaoh, he made the mistake of insisting that the Sphinx as a whole was carved by that pharaoh, and thus dates from the Middle Kingdom. Now that the Sphinx is cleared, everyone knows that the idea of the Sphinx having been carved as late as the Middle Kingdom is entirely ludicrous, and hence Borchardt's old idea is dismissed as complete nonsense. No one would even bother to read the article through today, so ridiculous does its conclusion seem. No one but me, that is. For I had a hunch that Borchardt was on to something. And indeed he was! His only mistake was to assume that the entire statue had to be of the same date. It never occurred to him that the head could be a later recarving. But, then, he had not seen the body, which was not yet cleared! It was impossible for him to draw the correct conclusion about the age of a sculpture that was still buried in sand.

Figure 4.10. This glass lantern slide circa 1900 shows the locals clambering all over the head of the still-buried Sphinx. Note the raggedy edges of lappets of the nemes headdress, later chipped off and made even by Selim Hassan in the 1930s when he extended them with modern concrete. Why is it that everyone wants to make the Sphinx more beautiful and ends up doing the opposite? (Collection of Robert Temple)

One curious feature of the head of the Sphinx is that the pharaoh is wearing a cloth over his head, which Egyptologists call by its ancient name, *nemes* headdress, or *nemes* headcloth. Colloquially, it has even been known as the King's Bonnet. It was worn throughout Egyptian history by pharaohs, and in itself it indicates nothing about date. It appears to have had a sacred character to do with preparation for death (or "eternal life," as the Egyptians would say), as we shall see. But no one knows why it has the peculiar shape that it has, or why it is of folded and starched cloth. The pharaohs had various crowns, which they wore as kings, but the *nemes* is not actually a crown, although it is sometimes called one. The pharaohs wore it in their religious role as opposed to their political role as ruler. It is therefore entirely appropriate that the pharaoh's face on the Sphinx gazes directly east, toward the sun rising on the equinox, in a pious mode, wearing the *nemes* in indication of the pharaoh's reverence for the rising sun god and in expectation of becoming the companion of that god in the afterlife.

The *nemes* is mentioned specifically in some of the ancient texts of the Early Middle Kingdom. In Spell 75 of the Coffin Texts, found on the coffin of an Egyptian of that period named Heqata, the deceased, who has declared his identity with the sky god Shu, boasts: "I have claimed my *nemes*-crowns from the One who is in his cavern. It is the One who is in his cavern who fetched for me my *nemes*-crowns." This clearly stresses the sacred nature of the *nemes*. The translator comments: "It here appears

that the *nemes*-crown is a necessary attribute in order to be able to ascend to the sky, and that 'Ruty, who is in his cavern' supplies it." <sup>7</sup>

Ruty, more often spelled Ruti, is the god described as "the One who is in his cavern." This cavern is also known as the House of Ruti, and it was necessary for any dead person to pass through it and collect his *nemes* to put on his head before proceeding to the House of Osiris, which was on an island, where he would be received in death by his "father," the god of the dead, Osiris.<sup>8</sup> And as we shall see later on, Ruti has specific associations with the Sphinx and with Giza. Ruti was an underworld aspect of the sun god himself, in his role of leaving the daytime barque of the sun and entering the nighttime barque of the sun<sup>9</sup> for his journey through the land of the dead, which was often envisaged as lying beneath the plateau of Giza and was imagined as being entered from the precincts of the Sphinx itself.

For the moment, all we need to know is that the *nemes* is a very appropriate covering for the head of the Sphinx, as it indicates religious reverence, and it is necessary for the deceased to put it on before proceeding to the World of the Dead and his eternal life.

The *nemes* seems to have been formed from a single cloth that was starched and folded in pleats, which then hung down over the shoulders. In the case of the Sphinx, the bottom portions of the *nemes* fell off and disappeared in antiquity, as the photos of figures 4.10 to 4.14 show clearly. At the present day, the folds of the *nemes* at the side of the Sphinx's face have continuations downward past the chin that are crude pieces of modern concrete, and which really ought to be removed, as they mar the edifice. They are examples of so-called restoration that are very clumsy and ugly.

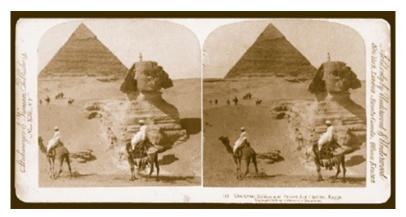

Figure 4.11. A stereoview of the Sphinx dated 1896, showing a man standing on the head of the Sphinx. (Collection of Robert Temple)

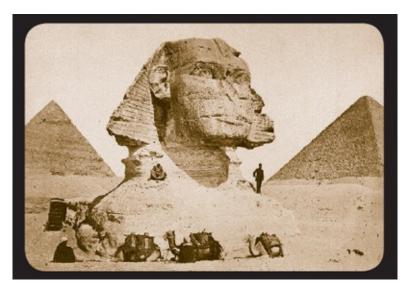

Figure 4.12. This is a photo of the Sphinx from the early nineteenth century. At this time, only the head and back of the Sphinx were visible, and visitors could clamber all over the chest. The wagon on the left in the photo provides a very useful indicator of

the scale of distance; it stands about midway along the Sphinx's body. This photo is particularly useful for showing the stripe patterns of the headdress, which were crucial to dating the recarved face. The deep hole between the eyes has long been filled with cement. Here, the extent to which the nose was broken off and the lips damaged, and the right earlobe broken off, can be clearly seen, though much of this is today disguised by restoration work. (*Collection of Robert Temple*)

Figure 4.13. A postcard circa 1890, showing the Sphinx as it was at that time. (Collection of Robert Temple)

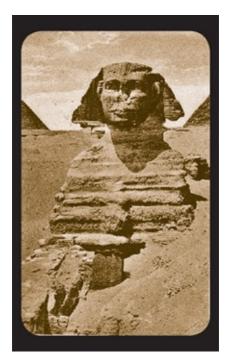

Figure 4.14. An old postcard circa 1900, showing the deluge of sand that has swallowed up the northern side of the Sphinx. (Collection of Robert Temple)

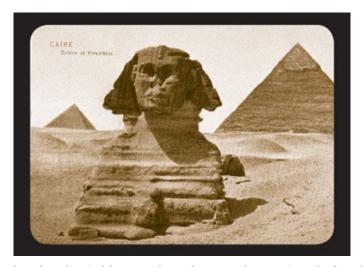

Figure 4.15. A postcard circa 1910, showing the Sphinx nearly as it was prior to 1817, before it was partially excavated in front by Caviglia. (Collection of Robert Temple)

Figure 4.16. An old postcard circa 1910, showing the Sphinx nearly swallowed again by sand. (Collection of Robert Temple)

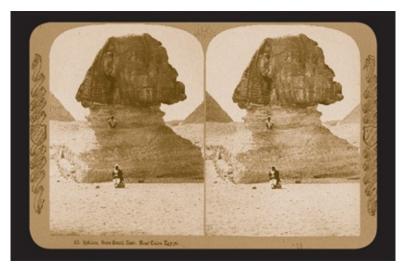

Figure 4.17. In this old stereoview of unknown date, the Sphinx is covered again in sand to the top of the chest. I think this photo may be circa 1870, by which time the sand had all blown back again, and the results of Caviglia's excavations were totally obliterated. (Collection of Robert Temple)

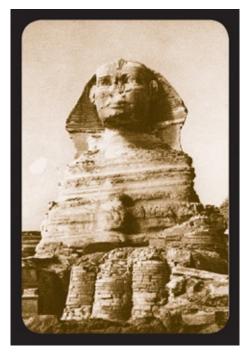

Figure 4.18. A postcard of the Sphinx from the late 1930s or 1940s, showing the terrible condition of the left paw at that time. The small stones are of Roman date, and many are about to fall off. Even the Romans were desperate to repair the eroded paw, but they did not do a very good job. (*Collection of Robert Temple*)

What Ludwig Borchardt decided to do, which no one else ever seems to have done, was to undertake

a scientific investigation into the details of the particular type of *nemes* headcloth worn by the Sphinx. He also took into account that the face of the Sphinx had eye-paint stripes, indicating a particular fashion that must have a specific date. He thought it might be possible to date these features, and he was right!

Borchardt begins by saying that he intends to approach the question of the dating of the Sphinx "from a different direction than has been done heretofore," and he dismisses the supposed evidence from the so-called Dream Stela between the paws of the Sphinx as being unreliable. By this he is referring to the partial appearance in that stela, erected during the New Kingdom, of what some maintain is the name of the pharaoh Chephren, known in Egyptian as Khafre. In fact, this name, if indeed it really is a name at all, has partially peeled off from the stela, so only a single syllable can be made out. As the word was not set inside a royal cartouche (an elliptical line drawn around every royal name by the Egyptians), it cannot possibly have been the name of the pharaoh Khafre, for not to enclose it in a cartouche would have been extraordinarily disrespectful, and another pharaoh would never have done such a thing. The context is also vague, so nothing can really be concluded from it at all. Borchardt also dismisses attempts to analyze the face itself, saying, "the face is so ruined that . . . one can scarcely infer anything from it."

He then says what his method will be:

In what follows, an attempt shall be made to arrive at a date based on details of dress, since for the present that seems to be the only safe way to date Egyptian sculptures, whereas for the treatment of such questions from the purely stylistic point of view there exists up to now neither sorted material nor sufficient preparatory work. We must for the moment content ourselves in the research which confronts us with settling the question solely as a matter of dress, by setting strictly aside all stylistic observations relating to the treatment of the actual portrait, the musculature and so forth, and thus reducing the question to something visibly obvious and tangible—or I might even say—numerical.

This makes a lot of sense, and one wonders why no one ever attempted it before, or, for that matter, why no one has attempted it since. Borchardt then proceeds to use his first method for dating the Sphinx's head:

The first criterion of this kind with which we shall deal concerns the eye-paint stripes which are found projecting from the outer corners of the eyes of the Sphinx in entirely flat relief and with traces of blue pigment. Regarding these, we should need to apply the law, recently discovered by Herr [Friedrich Wilhelm, Baron] von Bissing, that eye-paint stripes were unknown in the Old Kingdom. That this is so is shown by the following statistics, which unfortunately only refer to what is in the Cairo Museum, but which could hardly be modified by objects from other collections.

Figure 4.19. A close-up of the Dream Stela of Thutmosis IV. I took this photo of part of the text of the stela to emphasize the careful way in which all royal names in that text were written in cartouches (see the center of the photo), which is the ellipse in which a king's name was always enclosed. This is a crucial point to make, because a now-flaked-off word of the text began with the syllable *khaf*, and many people have tried to insist that this was a reference to the pharaoh Khafre, better known by the Greek form of his name, Chephren. However, everyone admits that this *khaf* was not enclosed in a cartouche, so it cannot possibly have been a reference to Khafre/Chephren, as it would have been impious and insulting to mention that king without enclosing his name in a cartouche such as that seen here in the intact portion of the text. In fact, King Khafre/Chephren is not mentioned in the text at all, nor is King Cheops. The Dream Stela can only be seen properly if you are standing beneath the head of the Sphinx, where only people with special permission are allowed. Normal tourists can barely see the stela in the distance, much less see any detail of it whatsoever. (*Photo by Robert Temple*)

The Cairo Museum possesses in its Old Kingdom halls and storage areas over 230 statues and fragments of statues with heads which date from the Old Kingdom [this was in 1897]; none of these have any eye-paint stripes.

He then points out that eye-paint stripes seem to have made their initial appearance during the Sixth Dynasty, which was the last dynasty of the Old Kingdom (2347–2216 BC):

We have the first appearance of eye-paint stripes during or after the 6th Dynasty, which was the time when all the radical changes in dress and customs appeared, which separate the Middle Kingdom from more ancient times, so that certainly in terms of the history of art, but perhaps also in the political sense, one can properly speak of the Middle Kingdom having begun with the 6th Dynasty.

What we have ascertained from the statues is shown also by the reliefs. Prior to the 6th Dynasty eye-paint stripes cannot be demonstrated anywhere, but thereafter they make their appearance everywhere.

So Borchardt then concludes on the basis of this criterion: "Now, the Great Sphinx has obvious eyepaint stripes. Therefore the time of its creation falls into the period subsequent to the Sixth Dynasty."

It is at this point that most or, to put it more bluntly, all of Borchardt's readers today would fling down his article in dismay, looking on this strange notion as Borchardt's greatest folly, or perhaps they would just laugh. After all, the idea that the Sphinx dated from some time subsequent to the Sixth Dynasty is just so silly that the man must be off his head. But as I have said earlier, we have to remember that Borchardt had never seen the Sphinx. He had seen only part of its head and the top of its back, and this article was published in 1897, nearly three decades before the Sphinx was properly cleared of sand. What Borchardt was doing was making an intensive study of that portion of the Sphinx that was readily visible, namely the head. And he certainly studied it more carefully than anyone before or since.

But if it were only the eye-paint stripes that Borchardt considered, we could always dismiss it by saying maybe he was wrong about that. Maybe there were earlier eye-paint stripes, but we have just lost the evidence. The really convincing part of Borchardt's analysis concerns something else entirely. He decided to look at the pattern of the stripes portrayed on the *nemes* headcloth. It is easy to overlook this detail, as such decoration seems merely gratuitous. And today it is difficult to see these at all, because you cannot get a high enough angle to see the top of the Sphinx's head directly anymore. Also, the sunlight needs to be right to get some contrast, and the glare of the sky can be a problem. The pattern of the stripes is now very difficult indeed to make out from ground level because we are too far below them to get a good look. But in Borchardt's day, it was easy. And thank goodness we have plenty of photos from that time, which record the stripe patterns unmistakably for us, as figures 1.16, 1.21, 1.22, 4.10, 4.12, and 4.18 make clear. After all, in the old days when one was standing at neck level looking the Sphinx directly in

the eye, it was hard to miss the stripe patterns.

In evaluating the analysis of Borchardt, we need to consult figures A, B, C, and D, which are reproduced from his article, and which are reproduced in appendix 2, along with the complete translation of that article. These show different stripe patterns used on *nemes* cloths. C and D show the patterns that actually appear on the Sphinx.

We need to follow Borchardt's analysis rather closely now, and to do so it is best to use his own words:

Just as this criterion has given us the lower date limit, so we can find the upper limit in the ornaments of the headdress, the so-called King's Bonnet. This decorated piece of cloth lying over the forehead with the uraeus, which is the symbol of the kings, is tied firmly to the forehead with a headband. It frames the face, creating two triangular areas which fall in two pleats on either side of the face down the neck onto the chest. At the back it is gathered together and ends in a plait lying down the back, which is ribbed as well as appearing to be wrapped. The pattern which this scarf shows is in most cases the following: the front folds are, as shown in A, both in frontal view and also in section, folded into horizontal pleats, the piece covering the head, however, is divided into regular alternately sunken and raised stripes (see figure B), which with statues of which the painting is still showing, is depicted in alternating yellow and blue shades.

This King's Bonnet was of course fashion-dependent, and so we can at least in the statues follow different variations through time. From the 18th Dynasty, or perhaps even a little earlier, it becomes fashionable to supply the inside with a vertical smooth hem. Around the 19th Dynasty it becomes common practice to extend the regular division of the stripes of the upper part of the front pleats to the chest by giving up the pleats, and at the same time they now divided the ribbed plait instead into sunken or raised horizontal stripes as well.

The Great Sphinx of Giza also shows yet another pattern in its headdress.

The stripes of that headdress given as sunken are arranged in groups of three stripes each, that is, one wider stripe is always placed between two narrower stripes. Each of the wider stripes has on either side a small accompanying stripe. And this differs from the usual arrangement with stripes of equal width. And therefore we have to examine where and when this anomaly occurs as well.

The following list which shows those kings' statues with the stripes which are grouped in this manner will show this immediately. We must distinguish between two different forms: those with completed groups (figure C) and those where they are only indicated in simple lines (as in figure D). Both types of course belong to the same type; the second is only an abbreviation to the first.

In a footnote, Borchardt makes clear that "we are always only speaking of the stripes on the upper part and the side part of the cloth. The regular pleating of those cloths falling over the chest are not considered here."

Borchardt then gives lists of statues, heads, and busts that were examined. He found six at the museum then at Giza, all from the Twelfth Dynasty of the Middle Kingdom. His friend Heinrich Schaefer, the famous expert on ancient Egyptian art, reported on five more of the same date in the Berlin Museum. In the Louvre, Schaefer found one more; none was found in the British Museum; but two were found in English private collections. These were the collections searched in person. A further search was made in photo collections of other museums, where no further examples were identified. As a result of this search, fifteen clear examples were found to substantiate Borchardt's thesis, and none was found to contradict it.

His conclusions were very clear and specific, and on this basis he suggests that there was probably only one pharaoh whose face could possibly be that of the Sphinx, the great and powerful Middle Kingdom pharaoh Amenembet III of the Twelfth Dynasty (1818–1770 BC):

Figure 4.20. A portrait of King Sesostris (Senusret) I (1971–1926 BC), the second pharaoh of the Twelfth Dynasty. His face is very different from that on the Great Sphinx of Giza, and the stripe pattern on his *nemes* headdress does not match it either. The Great Sphinx's face is clearly not his.

The grouped stripes on the King's Bonnet are only found during the 12th Dynasty, perhaps only under Amenemhet III, because those pieces which are precisely dated and which have such an arrangement of stripes are all from his time. And of the others which are only dated generally to the 12th Dynasty it can never be discounted that they also might be images of Amenemhet III. For this more narrow limitation of this fashion of stripes to the time of Amenemhet III speaks as well as the circumstance that the statues of [Pharaoh] Usertsen [now usually called by his other names, Pharaoh Senwosret III and Sesostris III; he was Amenemhet III's father] from Lisht (Giza, Numbers 411–420, Catalogue 1895, Supplement 3, Number 1365, Hall 21) have not grouped but merely regular stripes. But whether or not one wishes to limit the time of the grouped stripings to the reign of Amenemhet III, one thing is for certain: after the 12th Dynasty, this fashion has vanished. The statues of the 13th Dynasty, Sebekhotep (Louvre, Cast G 1, Catalogue S. 332, Berlin) and Sebek-em-sa-f (Giza, Number 386, Catalogue 1895, Number 128, Hall 16), already display the regularly striped King's Bonnet.

So for the dating of the Sphinx at Giza we draw from all of this the following conclusion: Because the headdress of the Sphinx shows the wide stripes with the narrow accompanying stripes, the Sphinx therefore can surely not have been created after the 12th Dynasty. We have now enclosed the origin of the Sphinx within two limits, an upper and a lower.

According to the makeup stripes it is 6th Dynasty or later. According to the stripes on the headdress, it is before the end of the 12th Dynasty. If one wishes to be less cautious, one can add to this perhaps the time of Amenembet III.

Borchardt cautiously adds: "Finally, if one really wants to, one could even read the type of Amenemhet III's face into the countenance of the Sphinx. But as I have said already in my introduction, this is a rather questionable argument because of the destruction of the features."

In my opinion, Borchardt's calm, reasoned, and logical approach is an absolute model of disinterested forensic analysis, far removed from any desire to prove or retain a theory for reasons of vanity and egotism. Although we shall see that Amenembet III is probably not the correct pharaoh, there seems to me no question whatsoever that Borchardt is accurate in insisting upon a Twelfth Dynasty face for the Sphinx, and that his analysis of the fashion of the headdress, and so on, was absolutely sound.

Figure 4.21. A leonine Middle Kingdom sphinx with the face of King Sesostris (Senusret) III (1878–1839 BC). His face is clearly *not* that on the Great Sphinx of Giza. Because this sphinx was later usurped and reused by a pharaoh of the Fifteenth Dynasty, whose members were foreign invaders from the east known as the Hyksos, this sphinx was for a long time known as a Hyksos sphinx, though we now know that they merely stole it and put a new name on it. (*Collection of Robert Temple*)

One of the aspects of the face of Amenemhet III that is particularly striking is his ears. Stadelmann criticized the suggestion that the face of the Sphinx was that of Chephren because he said the ears didn't match. The ears of Amenemhet III match those of the face of the Sphinx precisely! They are large and prominent and have the same conformation. Amenemhet III was also a very strikingly handsome man, and the general shape of his face matches that of the Sphinx, in a way that of Chephren most emphatically does not. A statue of Amenemhet III is shown in figure 4.22. If you hold this up side by side with a photo of the face of the Sphinx, you can see that the ears are the same. And the same stripe pattern is seen in the *nemes* headcloth, of the fat central stripe surrounded on each side by a thin stripe. If you look at works depicting most other pharaohs in *nemes* headcloths, you will not find this pattern, and they certainly occurred throughout Amenemhet III's reign, which lasted approximately 1853–1805 BC. (Officially he reigned for forty-eight years, but it is thought he really reigned for at least fifty.)

Figure 4.22. A statue of the Middle Kingdom pharaoh Amenemhet III when very young. (*Taken from plate 21 of Adolf Erman*, Die Welt am Nil [The World on the Nile], *Leipzig*, 1936)

After Borchardt's article was published, did anybody take it seriously? Wallis Budge referred to Borchardt's theory without mentioning Borchardt's name in the volume of his *History of Egypt* published in 1902, which dealt with the Middle Kingdom and Amenemhet. He writes: "A theory has recently been propounded which makes the head of the Sphinx at Gizeh [Giza] to represent that of king Amenemhat [Amenemhet] III, 'by whom it may be supposed to have been erected;' but no evidence in support of it has yet been adduced, nor have the old views concerning the Sphinx yet been proved incorrect." <sup>10</sup>

Since the statement "by whom it may be supposed to have been erected" does not appear in Borchardt's article, we must presume that Wallis Budge did not (or perhaps could not, since he evidently did not know German) actually read Borchardt's article itself, but rather relied on a superficial account of it elsewhere, perhaps in a periodical. It may be that Wallis Budge hesitated to mention Borchardt for this very reason, that he was drawing only on a secondary source and felt so unsure of his grasp of the details of Borchardt's argument that he did not wish to criticize him by name. It is also untrue, as we have seen, that "no evidence in support of it has yet been adduced," for Borchardt's article was in fact one long summary of overwhelming evidence; this proves conclusively that Wallis Budge did not (*could not*, for lack of knowledge of the German language) actually have read it.

In 1910, the eleventh edition of the Encyclopaedia Britannica appeared, and in the entry for "sphinx," Borchardt's article was cited. It was due to the fact that I have this edition of the encyclopedia in my home that I learned of the existence of Borchardt's article in the first place. Actually obtaining a copy of Borchardt's article was very difficult, though the hand of fate was at work, since I managed to purchase an offprint of it from a dealer in rare books in Germany. My facility for finding impossibly rare publications was certainly at work here, in what American slang describes as "big time." Translating Borchardt's article with the aid of my German friend Eleonore Reed was a tremendously difficult task for both of us, due to the extreme precision required in elucidating Borchardt's careful physical description of the kind we have already read. (Borchardt's full text in translation can be found as appendix 2.)

The only other reference to Borchardt's article in English that I have ever seen is in the large volume on the Sphinx by Selim Hassan published in 1953 at Cairo. He translates portions of the article into English, although not always correctly, and he does not agree with Borchardt for obvious reasons, having just personally excavated the Sphinx and cleared it of sand, proving beyond doubt that it was far older than the Middle Kingdom. But what never occurred to Hassan was that Borchardt's analysis of the face

might be accurate regarding the face alone. In fact, Hassan didn't think of the face as detachable from the body any more than Borchardt thought of the body as detachable from the face. The problem has always been that people cannot separate the two in their minds. They think of the Sphinx as a unity when it probably is not. The "unity" of the Sphinx probably ended in the Twelfth Dynasty, which is about the time when a very egotistical young pharaoh put his own face on the great monument that lay at the feet of the Giza Plateau. However, there is every reason to believe that the original head and face of the Sphinx was badly damaged by that time and beyond hope of repair, so an alternative was not really a bad idea. And let's face it (pun intended): the face of the Sphinx is sufficiently striking that we shouldn't complain. It inspires awe in all who see it, just as the pharaoh who put his face on it presumably hoped it would. Perhaps the extraordinary wide-open eyes are meant to indicate the eager gaze with which the reverent pharaoh peers at the eastern horizon, hoping to catch a glimpse of the sun god, who will rise at any moment. Normally Egyptian statues do not show the eyes opened so wide as this, for portraits tend to show kings in repose. But the face of the Sphinx is not in a state of repose; it is in a state of expectancy, as is appropriate under the circumstances of someone watching for the sunrise.

Who was this Amenemhet III, whose face Borchardt claimed may have been looking down on the rest of us for all these ages? He was a pharaoh particularly noted for immense building projects, for vast irrigation works, and also for an obsession with sphinxes! He lived in a peaceful era, didn't waste time making war on neighbors, and was one of the greatest builders in the entire history of Egypt. He built the famous Labyrinth at Hawara, which is now almost entirely destroyed (see figure 4.25). A few comments about Amenemhet from Wallis Budge's *History of Egypt* gives a good idea of the man. In the histories written by Sir William Flinders Petrie and Erik Hornung, little is said of Amenemhet, so it is necessary to quote from Wallis Budge, who gives him his due credit:

Amenembat [his spelling of Amenembet] III, the son and successor of Usertsen III [now called Senusret III or Sesostris III], was the greatest of all the kings of the XIIth Dynasty. . . . The whole of the energies of this king appear to have been devoted to improving the irrigation system of his country. . . . Amenembat III found Egypt in a state of great prosperity when he ascended the throne, and as the land had rest [was at peace] during his long reign, he was able to leave his country in a most flourishing condition at his death. Art, sculpture, and architecture flourished under his fostering care, and the remains of his buildings and inscribed monuments testify to the activity which must have prevailed among all classes of handicraftsmen during his reign. . . . The king's activity in building continued throughout the whole of his reign. . . . At [his] time the river level during the inundation was about twenty-six feet higher than it is at the present time [in 1902]. . . . [He] seems to have endeavoured [by annual measurements, which are recorded] to understand the effects upon the agriculture of Egypt caused by inundations of varying heights. . . . The greatest and most useful of all the great works which were undertaken by Amenemhat was the making of Lake Moeris in . . . [the] Fayyum. [The Fayyum is a giant oasis region southwest of Cairo, which has always been heavily populated and agriculturally productive.]. . . The largest circumference of Lake Moeris was about 150 miles; its area was about 750 square miles.  $\frac{12}{12}$ 

The most amazing building feat of Amenemhet III was the Labyrinth at Hawara in the Fayyum. It seems almost unbelievable that all but a few pieces of stone have now vanished. Wallis Budge says sadly:

The extent of the area of the Labyrinth is probably marked by the immense bed of chips of fine white limestone which lies to the south of [his] pyramid, and on tracing this bed to its limits, it is found that

they cover an area which measures 1000 by 800 feet. The principal part of the pavement to be seen is in the eastern half of the site, and some years ago it covered a tolerable space; but the builders of the railway into the Fayyum discovered the place, and took the stones away to build the line; thus the last remains of the wonderful building disappeared under the process of "civilizing" Egypt. 13

Figure 4.23 is one of my photos of Amenemhet III's mud-brick pyramid at Hawara, and figures 4.24 and 4.25 are the ones that I took from the top of the pyramid showing part of the remains of the site of the Labyrinth. To appreciate the magnitude of Amenemhet's building operations, one has to read the account of the Labyrinth left by Herodotus, the Greek historian of the fifth century BC, who visited it:

I have seen this building, and it is beyond my power to describe; it must have cost more in labour and money than all the walls and public works of the Greeks put together. . . . The pyramids, too, are astonishing structures, each one of them equal to many of the most ambitious works of Greece; but the labyrinth surpasses them. . . . The baffling and intricate passages from room to room and from court to court were an endless wonder to me, as we passed from a courtyard into rooms, from rooms into galleries, from galleries into more rooms, and thence into yet more courtyards. The roof of every chamber, courtyard, and gallery is, like the walls, of stone. The walls are covered with carved figures, and each court is exquisitely built of white marble [limestone] and surrounded by a colonnade. 14

It is extremely irritating to think that the pavement of this monumental construction was stripped away by railway engineers at the end of the nineteenth century and used for something so mundane as laying the bed of a railway track. In fact, this is one reminder that a great deal of the destruction of ancient Egyptian monuments has taken place more recently than we feel comfortable in admitting. Another example of this is the total demolition during the nineteenth century of a beautiful temple on the island of Elephantine. This all goes to prove that oafs are everywhere and active at all times.

Figure 4.23. This is the strange condition of Amenemhet III's Pyramid at Hawara in the Fayyum today. Unable to build pyramids in stone anymore, the pharaohs of the Middle Kingdom had to use mud bricks instead. Over the millennia, the erosion caused by rainstorms, sun, and wind have turned the once regular pyramid into this wonderful surrealistic work of art, a symphony of light and shade of a kind that the pharaoh never intended. No wonder that Amenemhet II sought to immortalize himself in stone in the only way he could, by carving his face on an older monument, the Sphinx! (*Photo by Robert Temple*)

Figure 4.24. The pathetic remains of the Labyrinth at Hawara in the Fayyum, which was once one of the Wonders of the World, as described by Herodotus. Now, the pockmarks in the sand and a few blocks of stone are all that is left. Even in the nineteenth century, huge portions of the Labyrinth were stripped away and the stone used as sleepers for the Fayyum Railway. If the railway were ever replaced and its stones salvaged, a considerable portion of an ancient monument could be recovered! This photo is taken from above, standing on the remains of the mud-brick Pyramid of Amenemhet, which itself is in no great shape. (*Photo by Robert Temple*)

Figure 4.25. The remains of the Labyrinth at Hawara, seen from the side of the mud-brick Pyramid of Amenemhet III. (*Photo by Robert Temple*)

So if Borchardt were right, we would have the comfort of knowing that the face on the Sphinx is evidently that of one of the greatest pharaohs in the history of Egypt, not just that of a nobody. And the enigmatic expression on the face, made more so by having lost its nose and by its other damage, does bear comparison with the flickering half-smile of Leonardo da Vinci's "Mona Lisa." And like the face of the Mona Lisa, its gender has been questioned. Serious suggestions have been made that the Mona Lisa is really a man dressed as a woman. And for centuries, the Sphinx's face was thought to be that of a woman, as countless early travelers relate. A touch of androgyny always makes a face more intriguing.

One other crucial fact about Amenemhet III is that he was obsessed with sphinxes, and that is certainly appropriate for someone who Borchardt suggests put his own face on the greatest sphinx of them all. There are several surviving small sphinxes that bear the face of Amenemhet III. These are well known to Egyptologists, and it is therefore puzzling that they don't seem to have put two and two together. When some of these sphinxes were originally discovered at the site of the city of Tanis, they were at first thought to date from a later period known as the Hyksos period. But eventually Egyptologists figured out that these statues had been "usurped" by the later Hyksos kings. The process known as "usurpation" was very common in Egyptian history. Lazy builders and sculptors simply plundered previous buildings and works of art and relabeled them. In fact, whole temples could be cannibalized in this way, and often were. One bust of Amenemhet III was usurped by the New Kingdom pharaoh Merenptah, and the lazy sculptor of the

later period had the audacity to chip away part of the face to make it look more like Merenptah! As Wallis Budge says, ". . . certain features, e.g., the muscles at the corners of the mouth, were altered by hammering in order to make them to resemble those of the usurper." As for the sphinxes found at Tanis, "We probably see good representations on those of the maker of Lake Moeris and of one of the greatest kings who sat upon the throne of Egypt." 16

As for his character, perhaps Amenemhet III was a madman and a megalomaniac, and perhaps he was not. It was singularly immodest of anyone to stick his face on the largest sculpture of Egypt, and whoever did it cannot have been without a considerable ego. But so it has always been in the affairs of our species, and so it will doubtless always be: the pushy ones think they are Ra's gift to humankind.

However, it is now possible to narrow down the search for the Sphinx's face even further. Yes, Borchardt was right about the dynasty. But no, he was not right about the actual pharaoh! It was not Amenembet III after all, but one of his predecessors in the same dynasty, and this fact must have generated Amenemhet III's own obsession with sphinxes. The final piece of the jigsaw has been inadvertently supplied by an Egyptologist named Biri Fay. Dr. Fay published in 1996 a large and impressive book, full of wonderful photographs, entitled The Louvre Sphinx and Royal Sculpture from the Reign of *Amenemhat II.* In this book, which is a truly amazing work of detailed analysis of a large sphinx in the Louvre in Paris (see figures 4.26 and 4.27), Fay discusses the fact that this sphinx bears the face of an earlier Amenemhet, not the one considered by Borchardt. The pharaoh she has in mind is Amenemhet II (reigned 1876–1842 BC), the third king of the Twelfth Dynasty, who reigned for thirty-four years, and who was the great-grandfather of Amenemhet III, who was its sixth king. Amenemhet II shifted his interest back toward the area of Giza, though most of his dynasty showed little interest in the region, preferring the region of the Fayyum farther south, where his father's and grandfather's pyramids were built. He built his own mud-brick pyramid at Dashur, which is not far from Giza. (The art of building pyramids in stone had been lost by this time.) And as we shall see, he seems to have undertaken something at Giza itself that was far more important.

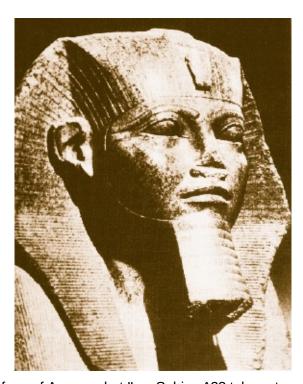

Figure 4.26. A view of the face of Amenemhet II on Sphinx A23 taken at an angle. (The Louvre, Paris)

Figure 4.27. The Sphinx A23 as King Amenemhet II, in the Louvre. His name appears in a cartouche on his chest. Note that the patterns of the stripes on his *nemes* headdress are identical to those of the Great Sphinx of Giza and as shown in the drawings in appendix 2, pages 510 and 511. This pattern was used only during the Twelfth Dynasty. (*The Louvre, Paris*)

Amenembet II seems to have been a restless fellow. He led an expedition to Nubia in search of gold when he was young. During most of his reign, there was a major emphasis on foreign relations, and he strengthened Egypt's presence and reputation in the area now known as Lebanon, particularly at the city of Byblos, which was a traditional Egyptian center. Certainly, Amenembet II was someone who looked outward and was not content to concern himself with only internal affairs. A considerable number of administrative documents survive from his reign, and also detailed annals of a portion of his reign were discovered carved into some reused stone blocks, one of which was only discovered in 1974. As the Egyptologist Jaromir Malek said: "The text appears to have been transferred to a temple wall from a 'day-book' written on papyri, and is the most detailed example of Egyptian annals (genut) known. . . . It will take a while to translate and understand it." That was in 1992, and we are still waiting for the translation and understanding to be published. However, the annals clearly show Amenemhet to have been preoccupied with visiting religious sites and cult centers and demonstrate that he had a fascination with ancient monuments. He described himself as "beloved of Atum" and "given life like Ra eternally." Both descriptions have a potential connection with concepts related to the Sphinx, which was often viewed as having a connection with the creator god Atum, as has already been mentioned and is discussed further later on in this book, and which faced the rising sun of Ra eternally.

As part of her study of the stone sphinx statue in the Louvre, which bears the face of Amenembet II, Fay does not mention, and shows no knowledge of, Ludwig Borchardt's article that we have just been considering, and which in translation forms appendix 2 of this book. She mentions other books by Borchardt, but it appears that she genuinely did not know that Borchardt had ever written a study of the Great Sphinx. If she had known of it, she might have drawn some rather different conclusions on certain matters. But fortunately *we* know it, so all is well.

The first thing that is evident from Biri Fay's book is that the triple-stripe design found on the *nemes* headdress of the Great Sphinx, which Borchardt had thought was used only at the time of Amenemhet III, was also used by, and apparently even introduced by, Amenemhet II (see figure 4.27). In fact, it prominently appears on the Louvre Sphinx, which is definitely known to bear the face of Amenemhet II. And furthermore, the eye-paint stripes are also there (see figure 4.28). These facts had been unknown to Borchardt.

So it is clear to us (but not to Biri Fay, who did not know of them) that all the arguments Borchardt so carefully marshaled in favor of Amenemhet III also apply to Amenemhet II. However, not for one instant does Biri Fay suspect that Amenemhet II's face might be the face that appears on the Great Sphinx. That is because she believes the conventional opinions and does not even think to challenge them. She accepts what is "known."

Figure 4.28. A close-up photo of the left eye and eyebrow of the face of Amenemhet II on the Sphinx A23, showing the eye paint and the *nemes* stripes discussed by Ludwig Borchardt in appendix 2. (*The Louvre, Paris*)

Biri Fay not only made a direct comparison between the face of the Louvre Sphinx and the Great Sphinx, she even published photos of the two faces opposite one another in her book, stressing their similarities! You might wonder how anyone who went this far could possibly not "see" the point! And yet she did not. Here is what, astonishingly, she actually says:

Although a stylistic comparison of the Giza and Louvre sphinxes must be restricted to their heads, similarities are profound. Both [kings'] faces are broad and full, and slope downward over the cheekbones (Plates 68 and 69) [her plates mentioned a moment ago]. Each nemes is wide across the wings, set low on the forehead over the brows, and shallow at the crown. On both sculptures, temple folds are rounded as they near the forehead. . . . The pleating pattern found on the nemes of the Louvre sphinx—a fine triple-stripe executed in rounded, raised relief, with a wide stripe and a narrow stripe to each side—is rare in the Old Kingdom [or absent!], but the treatment is similar on the Giza Sphinx (Plates 68a, 69a). In both cases, the stripes on the wings of the nemes fan upward behind the ears. A broad uraeus hood, with a wide ventral column, appears on both sphinxes (Plates 68–69). . . . . The eyes of both sphinxes are strikingly similar. Not only are they large in proportion to the face, but their shapes, with horizontal lower-eye rims and semi-circular upper rims, are closely related. Correspondence between the two works in the eye region extends to the shape and proportion of the wide brows, and broad cosmetic lines (Plates 68–69). Furthermore, in each case, the brows dip slightly at the root of the nose and extend horizontally over the eyes.

Among the most distinctive Louvre sphinx features is the broad mouth; the lips do not meet at the corners, but are instead embraced by a semi-circular muscle at each side. Despite damage suffered by the Giza Sphinx, its width is obvious, and close examination also reveals the muscled treatment of the

corners. . . . Comparison of three-quarter views further reinforces the resemblance of the Giza and Louvre sphinxes. . . . The fullness of the face across the cheeks and the slope beneath the eyes above the cheeks is analogous. As in frontal views, the eyes of both sphinxes are closely comparable, with horizontal lower eye rims and upper rims arched to a semi-circle. Furthermore, cosmetic lines embrace the sharp outer canthi [canthus is an anatomical term meaning the angle formed by the meeting of the upper and lower eyelids at either side of the eye], extend horizontally, and flare at the ends similarly on both sphinxes. Even though the ears of Louvre A23 are more damaged than those of the Giza Sphinx, it can be seen that the narrow helix and the antihelix [the helix is the outer rim of the ear and the antihelix is the curved elevation of the cartilage of the ear] branches compare well on both sculptures. Key similarities between the two works raise the question of whether Amenemhat II's sculptors also may have copied the maned shoulder style from the Giza Sphinx.

Plate 69c gives final demonstration of Amenemhat II's dependence on the Giza Sphinx for his own image. Images of both sphinxes laid over one another reveal that the sculptures are almost identical. . . . Amenemhat II used the Giza Sphinx as a model for his own sphinx. 19

Yes, reader, your optic nerve is not faulty, nor has your retina become detached. No, you have not lost your senses either. What you think you read is actually what you read. Yes, you have just read a meticulous comparison of the identical faces of the Sphinx of Amenembet II in the Louvre and the Great Sphinx of Giza by an expert analyst: she has gone to great lengths to prove that the two faces are identical, and yet she does not "see" what this means!

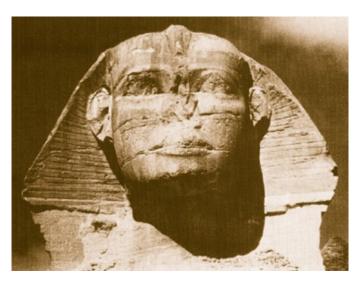

Figure 4.29. The face of the Sphinx of Giza, as reproduced in Biri Fay's book *The Louvre Sphinx and Royal Sculpture from the Reign of Amenembat II*, Mainz, 1996, as plate 68a. The photo credit reads "After Uni-Dia Verlag 10049."

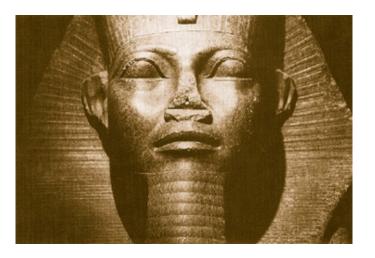

Figure 4.30. Amenemhet II's face on Sphinx A23, as seen from below eye level. This approximates more nearly the view of the face of the Sphinx of Giza as we see it today, from below looking up. (*The Louvre, Paris*)

Figure 4.31. Amenemhet II's face on Sphinx A23, seen head-on at eye level, the view that we have not had of the Great Sphinx of Giza since 1936, when it was fully excavated and we could no longer stand at that height. (*The Louvre, Paris*)

Figure 4.32. The face of Amenemhet II can be seen like this nowadays only from inside the Sphinx Temple. In front is the western wall of the Sphinx Temple. (*Photo by Robert Temple*)

Imagine me telling you that I had gone to Buckingham Palace and seen a woman who looked like Queen Elizabeth. I describe to you very carefully how her hair is exactly the same, she speaks like her, has the same expressions, has a lot of little corgi dogs standing round her ankles, has the same regal air, and could be her twin, she is so similar. I then go on to say to you very earnestly, apparently clueless as to any other possibility, that this woman has clearly modeled herself on the queen and made every attempt to resemble her and imitate her, and has even gone so far as to do so in the queen's own palace, and has borrowed the queen's own dogs to make her act of impersonation more convincing. What would you conclude about me?

There are some paranoid schizophrenics who see connections between everything. They think that if a bus passes them on a street corner, it is a "sign." They think that people who have no connection whatsoever resemble one another. But I would postulate an opposite condition: there are some people

who are so wholly in the grip of secondhand thinking that all their perceptual abilities, the evidence of their own eyes and ears, are powerless to alert them to anything that challenges conventional reality. Yes, there are actually people in existence who can describe point for point the precise resemblance of the faces of two sphinxes but do not even notice that this means that they *are* the same.

Biri Fay, having proved the identity between the faces of the two sphinxes, then goes on to insist that Amenemhet II had a face carved for himself on his sphinx statue in the Louvre that would resemble precisely that which was on the Great Sphinx of Giza.

Sedatives, anyone?

So now we have the answer to whose face is on the Great Sphinx. The face is that of the pharaoh Amenemhet II of the Twelfth Dynasty, who reigned from 1876 to 1842 BC. (And by the way, his ears were the same as his great-grandfather's.)

Now let us consider what the Sphinx was before it became a monument to one pharaoh's vanity. In the next chapter there is a completely different interpretation of the nature and purpose of the monument from any that has ever been advanced (except by myself in a brief preliminary account in 1998).<sup>20</sup>

## THE SPHINX AS ANUBIS

The first time I went to Egypt and saw the Sphinx with my own eyes, I was deeply shocked. Photos of the Sphinx are misleading in several respects. We have already seen in the previous chapter how hard it is from a photo to get a true impression of the proportion of the head to the body. And when I first saw the Sphinx, the ridiculously tiny head on the huge body was naturally one of the things that most shocked me. But what struck me even more was that the Sphinx did not look at all like a lion. I had always been told the Sphinx had the body of a lion with the head of a man, and I accepted that account as being true, as everyone does, since who are we mere mortals to challenge such a fundamental "truth" that "everybody knows"? It had not even occurred to me that there could be anything wrong with this "truth." But now that I stood there staring at the Sphinx with my own eyes, I failed to see a lion anywhere. No matter how hard I looked, I could not see a lion.

I rubbed my eyes, I examined my conscience, I craned my neck, I stared and stared, thinking that the obvious would soon become apparent to me if I just looked harder. Surely there was a lion there somewhere, as "everyone knows" that there is a lion there. We have all been told that there is a lion there since we were children. There is no one who does not see a lion there. We all know that. *But there was no lion*.

Olivia looked and looked, and there was no lion for her either. But she is rather more cautious than I am, and she wondered if perhaps we lacked some faculty that other people have, an *ability to see lions*. Were we somehow lion-dyslexic? Was this a failing of our own? Had we not consulted properly? Was this somehow our fault? But she has a good eye and notices shapes and forms and recognizes sil-houettes, and her reaction was that this shape was not that of a lion. She thought it looked more like a crouching greyhound.

This was one of those disillusioning moments in life, like realizing that there is no Santa Claus, when all your hopes and dreams are stripped away from you and you are forced to face a hostile reality. There we stood, sadly looking at the Sphinx that "everybody knows" is a lion, and we could see plainly that it was no such thing. We felt very lonely, and I knew that when I eventually came to write about it, I was going to have another one of those tedious and hard battles that I am always having when I try to point out that the emperor has no clothes. Because nobody wants to hear, and everybody tells you to shut up and calls you a troublemaker. And although I don't care whether I am called names, and just laugh, it does get a bit wearing sometimes, like being in a ferocious gale, so that you are always pulling your scarf tighter to keep out the wind.

Well, there we were, stuck with the reality that wouldn't go away: The Sphinx was something, but it

certainly wasn't a lion.

So what was it? It had four legs and it was lying on its belly, in a position that is generally called recumbent, or to use a term from heraldry (whose terminology as used in English derives from Norman French after the conquest of England by William the Conqueror, who came from Normandy), *couchant*. In discussing the iconography of the Egyptian gods portrayed as animals, it is common for Egyptologists to refer to a standing animal as "an animal *passant*" and a recumbent animal as "an animal *couchant*." People who are not familiar with these heraldic words need to have that explained to them. What kind of recumbent beast was the Great Sphinx *couchant*, then? One can't tell much from the paws, because they had been so mangled by restoration work (much of it apparently in Roman times) and covered all over in small stone blocks that they could give no reliable clue as to what type of creature this might be. None of the original carved portion of the paws is any longer visible, so what they looked like originally can be determined only by inference or by guessing.

The thing that struck us as most obvious and most peculiar was that the back of the Sphinx was entirely straight, that is, its spine was absolutely flat. It did not rise anywhere, whether in the rear or in the front. It was *flat*. (This is clearly shown in figures 1.11, 1.33, 1.34, 1.38, 1.39, 2.16, 2.18, 2.19, 2.26, 3.10, 3.15, 4.1, and 5.11.) All Egyptian statues and pictures of lions show the back rising sharply in front, to indicate the massive chest of a lion, and generally a mane is also clearly shown, as well as muscular haunches. See figures 5.1, 5.2, 5.3, 5.4, 5.5, and 5.6 for examples. But the Sphinx has no massive lion's chest, no rising line of the back to a higher neck, no bulging muscles, and certainly no trace of a mane. Figure 5.5 shows what a real crouching lion looks like, and it is clear to anyone that it has no similarity whatsoever to the Sphinx.

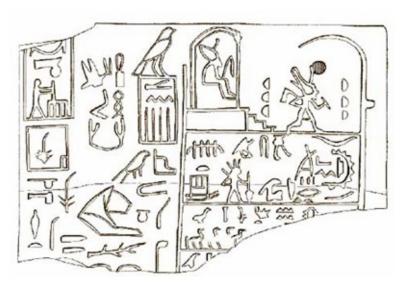

Figure 5.1. The design carved into an ebony tablet, which was found in the tomb of the First Dynasty king Den, who is seen seated on a throne within a shrine at the top center of the picture. At top right, the same king is seen running as part of the Sed Festival for renewing the magical power of his kingship, where he had to prove his vitality and virility by running back and forth within a sacred enclosure during the festival, carrying his royal insigniae and wearing the royal crowns and a ceremonial kilt. Behind the seated king, a Horus falcon stands on a rectangle called a *serekh*, the upper part of which contains the name of the king, Den, shown by two hieroglyphs (the wavy line is the hieroglyph for the consonant *n*). This is from plate XV of Flinders Petrie's *The Royal Tombs of the First Dynasty*, Part 1, 1900. King Den's tomb contained "a great number of tablets of ivory and ebony . . . twenty tablets are known from this tomb" (Petrie, p. 11). The recumbent lion, whose forepart is depicted at lower left, could not be further from the conception of the Sphinx of Giza. The lion was always conventionally portrayed, throughout the whole of Egyptian history, as having a massive chest and mane.

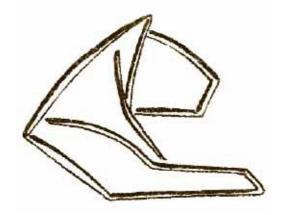

Figure 5.2. Detail of the lion seen in figure 5.1.

Figure 5.3. Here are seven examples of how lions were actually depicted by the ancient Egyptians prior to the carving of the Great Sphinx of Giza. These are small ivory carvings of lions that are thought to have been used as gaming pieces. They all date from the First Dynasty, the date of which is generally given as approximately 3050–2850 BC. All Egyptologists believe this to be well before the date of the carving of the Great Sphinx, which is generally attributed to the Fourth Dynasty (thought to have been approximately 2640–2510 BC). In other words, these lions are all at least two hundred years older than the Great Sphinx, if conventionally accepted dates are correct, and some may be four hundred years older. These lions, and others like them that have been recovered from royal graves, are known to have been carved over a span of several centuries. They prove that there was a well-established tradition in Egypt of how lions were to be represented in art. These lions are all zoologically accurate, as Egyptian art always was. Lions have massive chests, their backs rise steadily from their rumps into a thick, maned neck. We all know what lions look like, and so did the Egyptians of the First Dynasty. These ivory figurines prove that anyone who tries to maintain that the Great Sphinx is intended to represent a lion because the earliest Egyptians were naive in their art and showed them like that is wrong. These lions were all excavated beside an early temple at Abydos by Sir William Flinders Petrie in 1902/1903, and published in plate 3 of volume 2 of his book *Abydos*, *24th Memoir of the Egypt Exploration Fund*, London, 1903.

Figure 5.4. This is a detail of a carving at the Temple of Amun at Karnak. It shows the traditional form in which a lion's head and forelegs were represented in Egypt, with massive mane, wholly unlike the Sphinx of Giza. (*Photo by Robert Temple*)

Figure 5.5. This limestone votive figure of a lion was excavated between the forelegs of the Sphinx in the Sphinx chapel by Selim Hassan in 1936. It is plate XXIIa (following p. 50; the discovery is described on p. 33) in *The Great Sphinx*, figure 4 (opposite p. 36) in *Sphinx*, and figure 4 (following p. 24) in Le Sphinx. This depiction of a lion is so dissimilar to the Giza Sphinx that it shows strikingly how nonleonine the Sphinx's body is according to Egyptian artistic traditions.

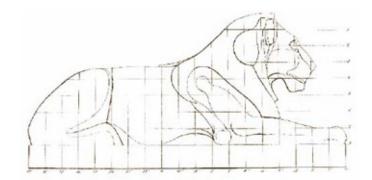

Figure 5.6. This ancient Egyptian drawing of a lion with its accompanying measurements marked off by the artist gives conclusive evidence that lions had a canonic mode of portrayal in Egyptian art, with a sharply rising neck, utterly unlike the shape of the body of the Sphinx, which cannot therefore have been intended to represent a lion. Lion bodies were also squat in contrast to elongated dog and jackal bodies like that of the Sphinx. The drawing also shows how conscious the Egyptians were of correct proportion in representations of animals, and on this basis alone, it is inconceivable that the tiny pimple of a head on the vast body of the Sphinx of Giza could possibly be original. (*Reproduced from Richard Lepsius*, Der wichtingsten Urkunden des Aegyptischen Alterthums, *Leipzig*, 1842, *Plates (Atlas) Volume*.)

Figure 5.7. The goddess Sekhmet (She of Power), with a solar disk on her head. This statue, covered in sheets of beaten gold, is of New Kingdom date. It is on display in the Egyptian Museum at Cairo. Sekhmet embodied various attributes. On the one hand, she presided over healers and protected women. On the other hand, she could be intensely destructive, especially to the wicked. She embodied the essence of the fiery midday sun, the destructive power of solar rays, and the hot breath of the burning desert, and she acted as a burning Eye of Ra to destroy those who mocked the sun god. It was necessary to keep on the right side of

her, for her destructive powers were awesome. She loved Cosmic Order and detested evil and was known as the Lady of Terror, feared by the wicked. She was the special protectress of the pharaoh in battle and was sometimes viewed as his nurse or even as his mother. The pronounced leonine characteristics of the head and neck of Sekhmet are far from what we see on the Sphinx. This statue may have represented a priestess of Sekhmet wearing a Sekhmet head, or it may represent the goddess herself. (*Photo by Robert Temple*)

So why do people call this statue a lion? It has no leonine characteristics at all.

The Sphinx was thought of as having the body of a lion for a very long time indeed, and it was the Egyptians themselves who started this misconception. When the Sphinx was cleared of sand during the New Kingdom by the pharaoh Thutmosis IV, circa 1400 BC, the Egyptians of that time thought they saw a lion. So from then on, it was assumed by many people that the Sphinx was a creature with the body of a lion and the head of man, much as people assume today. This fallacy is thus not a modern one. It has been believed for 3,400 years. But just because something is believed for 3,400 years does not mean that it is correct. For many thousands of years it was believed the sun went around the Earth, and that was not true either.

Many people have commented on the strange fact that there is no mention of the Sphinx in very early times in Egypt. To give a recent example, Mark Lehner has said in *The Complete Pyramids*, "There are no known Old Kingdom texts that refer either to the Sphinx or its temple." But I would say that the reason for this is that people have been looking for the wrong things. Texts referring to a lion with a man's head will not be found, because that is not what the Sphinx was.

This opens up all kinds of possibilities. If the Sphinx was not really a lion with a man's head at all, then of course there would be no Old Kingdom references to such a thing. We have already seen that the man's head was probably a recarving during the Middle Kingdom. So in the Old Kingdom, what we have to do is look for references to *something else* that might be the Sphinx, and which is neither a lion nor an animal statue with a man's head.

We will see that there are numerous references to *something else*, which was a gigantic creature that is sometimes specifically said to be at Giza. But it was not a lion, and it did not have the head of Amenemhet II, who was not born yet!

But before we turn to ancient Egyptian texts, we need to consider what the Sphinx actually is, or should I say *was*, before it had its head recarved. In the previous chapter I said that I believe the Sphinx once had an animal head. But clearly I do not believe it had a lion's head, since I do not believe it was ever meant to represent a lion. Whatever the head was, it needed to be in the correct proportion to the body. So we come to the question: What beast could this be, lying on its belly, guardian of the necropolis of Giza?

The usual guardian of the necropolis in Egyptian tradition was the god Anubis, and he was represented as a dog, or jackal, or jackal/dog. (See figures 5.18 and 5.9.) Anubis is the Greek name of the god called in Egyptian Anpu, but since everyone uses the form Anubis, we shall call him Anubis. In fact, there is no real agreement as to what precise creature Anubis is. Some think that there was a wild dog in those days that looked like this, or the creature may have been a cross between a jackal and a dog. In the thousands of years that have elapsed, it may well be that this precise breed has disappeared. There is a surviving dog today called the pharaoh hound that is close to Anubis in appearance, and the pharaoh hound was long presumed to be descended from those ancient dogs representing Anubis. People who have pharaoh hounds are very enthusiastic about them; there are even pharaoh hound clubs and newsletters and so forth. Anyone curious about them only needs to enter "pharaoh hound" into an Internet search engine. However, in 2004, a study of dog genetics suggested that pharaoh hounds are not related to ancient

## Egyptian dogs.<sup>2</sup>

The Egyptologist Alberto Bianchi has actually published an article claiming that Anubis was a wild dog, and he says, "The image of the sitting dog as Anubis protects the deceased." He says the position is a natural posture for the wild dog: "As is common with dogs, they adopt when they are resting a characteristic position consisting in projecting their four legs forward, parallel to one another, keeping at the same time an attitude of watchful attention. Surely, the observation of this peculiarity on many occasions, mainly by the people working in the cemeteries, resulted in its being given a transcendent meaning, linking it to the protection of the dead and the burials." Certainly this is the precise position of the Sphinx, which thus conforms exactly with the natural position of the Egyptian wild dog as a guardian.

Figure 5.8. A depiction of a crouching (*couchant*) Anubis carved in granite, in a block surviving among the ruins of Memphis. It dates from the period of the New Kingdom and shows Anubis in his characteristic pose. (*Photo by Robert Temple*)

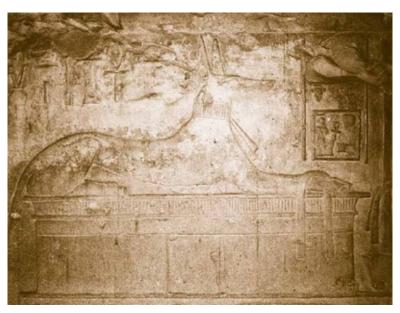

Figure 5.9. This photo of a crouching Anubis resembles what the Sphinx of Giza originally was, although the Sphinx of Giza has a straighter back. However, as an idea of what the Sphinx of Giza originally looked like prior to 2000 BC, this gives a very good impression. This is a wall carving at the Temple of Seti I at Abydos, and therefore dates from the New Kingdom, at least a thousand years later than the time of the carving of the Sphinx of Giza. (*Photo by Robert Temple*)

Bianchi further tells us (I have omitted his many references):

The jackal is usually considered by some authors as the Anubis canis, but this assumption must be discarded now because of its inconsistency. L. Keimer emphatically denies the existence of the jackal in Egypt. . . . E. Meyer wrote that the Anubis animal was a dog. . . . The Greeks did not know about the existence of the jackal . . . . E. Meyer took from inside a statue of Anubis found in the XVII nome [a geographical district] of Upper Egypt the mummy of a dog. . . . A. Gardiner in his Egyptian

Grammar questioned the interpretation of the sitting dog as a jackal in E17. . . . In fact, zoology has established differences in size and skull shape between the archetypal dog and the jackal which can be appreciated with a simple eye inspection.<sup>5</sup>

So we see that many experts have suspected that Anubis was not a jackal at all, but a wild dog. In the discussions that follow, including various quotations from authors, we should keep this in mind, and mentally correct the word *jackal* to *wild dog* when we are considering Anubis.

As I looked at the Sphinx that first time, noting the straight back of the creature and the complete absence of leonine features or characteristics of any kind, I was struck by the fact that I appeared to be staring at a dog. It looked like a dog to me, and it looked like a dog to Olivia. Perhaps this is because we are dog-lovers. However, if we had been cat-lovers, we would have thought no differently. There it sits, crouching on its belly, and it is a dog. And what is more, Anubis was frequently represented in precisely that posture throughout the thousands of years of Egyptian art. Anubis recumbent, or Anubis *couchant*, is one of the most famous of all ancient Egyptian art motifs. A magnificent small statue of the recumbent Anubis was recovered from the tomb of Tutankhamun.

In the countless images of the recumbent Anubis, he lies in precisely the manner of the Sphinx. Anubis always has a long tail, and the Sphinx has one. But because the jackal/dog was a slender creature, he is normally shown with a hollow beneath the lower part of his belly, where his slim form curves upward. However, in the case of the Sphinx, which was carved out of the solid rock, a portrayal of this feature would not have been possible without boring a large hole beneath the haunches and seriously weakening the statue. On the other hand, it is possible that the fissure at the haunches where the shaft had been bored and that is now filled with cement may have shown some sort of Anubis-like indentation, which contributed to the weakening of the stone at that point. If you look at the photo of the Sphinx in figure 1.31, taken before Baraize filled the fissure with modern cement, you can see that the body does seem to narrow somewhat at that point. But it is now difficult to be certain of such a feature, with so much "restoration" having taken place. The colored plotting of repair blocks published by Mark Lehner indicates that the area is now completely covered with repair blocks, with none of the original stone showing, and that many of these date from the 1960s–1970s. Since no one ever seems to have suspected that the Sphinx was Anubis before, it is evident that no one ever gave any thought as to whether any hollowing of the sides existed here originally. But if you look at the plan of the Sphinx from the air, you can see that the body clearly narrows at the haunches on both sides in the manner of Anubis. (See appendix 5.)

Figure 5.10. This detail of an incised carving in a stone vase found in the tomb of King Zer (Djer) of the First Dynasty shows a recumbent Anubis and demonstrates how unlike a lion the crouching dog was from the earliest depictions in Egyptian art. The straight back resembles the Sphinx.

Because the Sphinx has definite canine features and no leonine features, the burden of proof is shifted to those who wish to maintain that it is a lion to establish their case. Otherwise we must presume it is a

dog. But since there is nothing anyone can bring forward in favor of the Sphinx being a lion but hearsay (i.e., "consensus reality") and the late tradition from New Kingdom times of 1400 BC, when nothing was remembered about the true nature of the Sphinx in Egypt, the case for the Sphinx being a lion is lost. That this has not been recognized for 3,400 years is logically irrelevant: the principles of logic, Occam's razor, and common sense all dovetail in favor of the Sphinx being a dog. The fact is that 3,400 years of "the opinion of the herd" is of no more consequence than a flyspeck when it comes to the determination of the truth. Human beings are notoriously unobservant and poor at using their brains, and they tend to allow their thinking to be done for them—second-hand thinking, such as that which is provided for them by numerous churches, religions, political parties, sects, and cults. Humans think in packs, just as wolves run in packs. A human often likes to plug his or her hard disk ("brain") into a network and have all the thinking done remotely. It so much easier.

Figure 5.11. At left we see a redrawing of the shape of the Sphinx as it would have appeared in the Old Kingdom, when it was a crouching Anubis. The exact profile and proportions of the Sphinx have been incorporated into the drawing, and the head of Anubis has been added in correct proportion to it. The recarved head of the Sphinx with a pharaoh's face fits within the neck of what I believe to have been the original whole statue. At right is another redrawing of the shape of the Sphinx, this time in full-face view, and once again, the recarved head of the Sphinx with a pharaoh's face fits within the neck of the original statue. (*Drawings by Daud Sutton*)

We have already seen in figures 3.15 and 4.1 the disproportion of the Sphinx's head to its body. Now, in figure 5.11, we see the same side view of the Sphinx with a head of Anubis drawn on top in proportion to the body, and we can see that the existing head fits well within the neck of the dog. We can also see the same in a front view. The side folds of the headdress are well inside the span of the shoulders, whereas for a head in correct proportion, they would be expected to spread widely to either side of the shoulders. From these drawings, it is clear that the existing head could easily have been carved out of the neck of Anubis. And indeed, the proportions are such that in order to do this, a head of approximately the size that we now see would have resulted.

But one question that arises is this: Would anyone have dared to commit such an atrocity as to cut off the head of Anubis? Wouldn't that have been considered an extreme impiety? Doubtless it would, and even the most megalomaniac of pharaohs might have hesitated to do it. We have already seen in chapter 3 that in oral folklore a tradition of the head having been cut down still survives, so it must have made quite an impact on the locals to see this happen, a shock that survived in local lore for millennia. (We should remember that the very locals who said that the head had been cut down had never seen the body, which further confirms the accuracy of their tale, since they themselves were unaware of the disproportion between the head and the body, as they had never actually seen the body.) So what I believe may have happened is that when the Sphinx/Anubis became covered up with sand after the end of the Old Kingdom, in the long, dark days known as the First Intermediate Period, when civilization largely collapsed and there was no law and order and barely any government at all for a century and a half, the head of Anubis must have become damaged. Perhaps it was even vandalized. It must have been easy for a head with a long pointed nose and high pointed ears to be damaged, especially when the sand had risen up to the neck.

We know that the stone of the Sphinx is fragile in places, and a large piece of the Sphinx fell off into the Sphinx Pit in the 1990s. If the ears and nose of Anubis were substantially damaged, whether by weakness of the stone or by intention, a reshaping of the head might have been seen as the only sensible course of action to take by the time of the Middle Kingdom. So we must not assume that Amenembet II was so crazed with egotism that he smashed the face of Anubis. His egotism may have been restricted to putting his own face onto a statue whose original face was so damaged that it had to be replaced with *something*.

We are encouraged to think along these lines by an article published by Zahi Hawass in 1992, in which he writes:

In my opinion, it seems most likely that the Sphinx was abandoned at the end of the Old Kingdom and then plundered in the First Intermediate Period, ca. 2150–2040 BC. This conclusion is suggested by the evidence of plundering on the Giza Plateau at this time, the scope of which could arguably have also affected the Sphinx. . . . Evidence from the lower temple of Khafra [Chephren; Hawass is referring to the Valley Temple] supports the hypothesis that the monuments on the Giza plateau were viciously destroyed at the end of the Old Kingdom. The temple was certainly robbed, and most of the statuary was smashed, as the many statue fragments in the area testify. The careful burial of the diorite statue of Khafra found in the pit in the antechamber suggests an attempt to protect it from plunderers.

All the cited evidence suggests the monuments of Giza were plundered in the First Intermediate Period. The Sphinx was most likely also abandoned at that time.<sup>7</sup>

I believe that Hawass is absolutely correct in his belief, and that the Sphinx was very seriously damaged and mutilated during this period. The head of Anubis would have been an easy target and was bound to have been vandalized. The ransacking of the adjoining temples, the smashing of all the statues in them, could hardly have taken place while the Sphinx remained untouched. So we should not condemn Amenemhet II unreservedly for putting his face on the Sphinx, considering that it was probably impossible to restore the head of Anubis correctly.

The so-called Inventory Stela excavated at Giza preserves a tradition of the need for repairs to the Sphinx in the early period, by claiming in its text that Cheops in the Fourth Dynasty *repaired* the Sphinx.<sup>8</sup> (The Inventory Stela may be seen in figure 5.12, and a diagram of its contents may be found as figure 5.13.) That claim would indicate the Sphinx being repaired as early as 2500 BC! If the Sphinx needed repair that early, imagine how much more repair it would have needed five centuries later, in Amenemhet II's time. But all Egyptologists get very upset these days when one quotes the Inventory Stela. Although many distinguished Egyptologists of the early twentieth century accepted its evidence and believed that the Sphinx was so old that Cheops had repaired it, today we realize that the Inventory Stela is a much later stela, and its evidence about that point cannot be reliable. But although the stela is clearly of a late date (we think circa 1000 BC) in terms of its carving, that is an insufficient basis for dismissing its text as being of the same age. The texts of the Taharqa edifice (King Taharqa, a Nubian pharaoh of Egypt of the Twenty-fifth Dynasty, ruled 690-664 BC) are also late but are not only accepted by everyone as being copied from texts of much earlier date, but many of them have been proved to be direct quotes from texts also inscribed in a chapel of the earlier pharaoh Rameses III (ruled 1198-1166 BC according to one chronology, or 1183-1151 BC according to another), five hundred years earlier, and who in turn must have obtained them from papyri of a much earlier date still. There are countless examples of texts being recycled throughout the ages in Egypt, and the text of the Inventory Stela is not necessarily entirely a late text just because the stela is late. Things are not as simple as that. But on the other hand, it is not certain that it was Cheops who really restored the Sphinx in the manner described (although there may have been a surviving tradition that Cheops had also restored the Sphinx even earlier), and it was possibly a New Kingdom pharaoh rather than Cheops who is referred to in the text, with the name changed. The main point is that there was a definite tradition of repairs to the Sphinx, which we know in any case to be true, since we have clear proof that Thutmosis (Thothmes) IV cleared and repaired the Sphinx, as we have seen in an earlier chapter and which is recorded in his Dream Stela, a fact accepted by everybody today.

But before we dismiss entirely the idea that the Sphinx was actually repaired by Cheops, let us keep in mind that there are many Old Kingdom repair blocks on the Sphinx, some of which are clearly visible in figures 5.14 and 5.15. These are the only really good repair blocks ever used on the Sphinx, and they have survived for about 4,500 years. All subsequent ones, including modern ones, are very inadequate. Who put these on the Sphinx? Maybe it was Cheops after all. It does look like Fourth Dynasty work. So what is the real answer to the age of the Sphinx, if it was *repaired* in the Fourth Dynasty? Some Egyptologists who admit the age of those blocks claim that they were put on the Sphinx at the time of its carving to remedy deficiencies in the rock. But that seems rather a tepid argument, and not particularly convincing. It is more likely, in my opinion, that Anubis was already there at the time of Cheops. But that is merely an opinion, and we shall see what is revealed in the future about the date of the Sphinx. I have worked on an archaeometrical dating project at Giza with the permission of the Egyptian Supreme Council of Antiquities, but as the results are not published yet, I cannot say more at the present time. Some indications of the results at Giza will be given in my next book, *Egyptian Dawn*. They are very surprising, and include dates for the so-called Osiris Shaft beneath the Chephren Causeway, which is 150 feet beneath the surface.

Figure 5.12. A photograph of the famous Inventory Stela, excavated at Giza. This stela includes a text claiming to date from the Old Kingdom, which describes the topography around the Sphinx. The stela itself is much more recent, perhaps from the Twenty-sixth Dynasty (664–525 BC). No one is certain whether the text is authentic and was copied onto this stela or whether it was written at the time of the stela, perhaps garbling some of the information. This photo is plate LV, following page 140, in Selim Hassan's extremely rare excavation report on the Sphinx, *The Great Sphinx and Its Secrets*, Government Press, Cairo, 1953. A diagram of what appears on this stela is shown in figure 5.13 below.

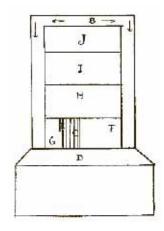

Figure 5.13. This diagram shows the locations on the stela where the different blocks of text and illustrations occur on the Inventory Stela. This is figure 80 on page 113 of Selim Hassan's *The Great Sphinx and Its Secrets*, Cairo, 1953. The stela lists the figures of the gods found by Pharaoh Cheops (Khufu) when he discovered the Temple of Isis at Giza. The Temple of Isis that is known to archaeologists (see figures 1.24, 1.25, and 1.27 on pages 30 and 31) is much later than the time of Cheops, so either there was an earlier Temple of Isis at Giza or this is a late text (perhaps from the seventh century BC) based on garbled information. The inscription along the right edge, beneath the downard-pointing arrow, says: "Live Horus Medjdu, the King of Upper and Lower Egypt, Khufu, given life [i.e., deceased]. He found the House of Isis, Mistress of the Pyramid, beside the House of the Sphinx, on the north-west of the House of Osiris, Lord of Rostau; and he built his pyramid beside the temple of this Goddess." The House of Osiris is thought to be what we now call the Valley Temple at Giza, either before it was usurped by Chephren and filled with statues of himself (if he did usurp it) or otherwise what it became after Chephren's statues were smashed and it reverted to a religious rather than a royal use. The bottom register of the panel then continues: "The Place of the Sphinx, Horemakhet, is on the south of the House of Isis, Mistress of the Pyramid, and on the north of Osiris, Lord of Rostau." This information is so specific that is seems impossible for the House of Osiris of Rostau to be anything other than the Valley Temple of Giza. These texts are so interesting that, whatever their age, we are glad to have them.

Figure 5.14. This photo of part of the southern rump of the Sphinx is what the French might call a *mélange des pierres*, or we could say "a stone cocktail." Just about every kind of patching and reconstruction stone that we could imagine is evident here, the palest ones being the newest. Underneath we see what are believed to be Old Kingdom repair stones. But this raises the question: If it was thought necessary to *repair* the Sphinx in the Old Kingdom, how old really *is* the Sphinx? We see here that later repair stones were laid over the Old Kingdom ones as an entire second skin, and this could have been done anytime during the Middle Kingdom, New Kingdom (after Thutmosis IV cleared the structure of sand), Ptolemaic, or Roman period. The large second-skin repair blocks, especially the long, curving stretched ones, are too sophisticated for Roman repairs and must be earlier, since the Romans used very small stones similar to the modern ones. One wonders just what really is beneath all these stones, and where the carved body is. (*Photo by Robert Temple*)

In 2005, Terence Du Quesne, with whom I enjoy a friendly and congenial acquaintance, brought out a definitive book on the history of the iconography and inscriptions relating to the god Anubis from the beginnings of Egyptian civilization (what is called the Archaic Period) up to approximately 2000 BC (the date at which the Middle Kingdom began). This book deals not only with Anubis per se, but also with variant forms of Anubis and other jackal deities. It is called *The Jackal Deities of Egypt* and is the product of a lifetime's study of the subject. Like myself and Olivia, Terence is a real dog-lover! We will consider this book as well as earlier publications by Du Quesne a little later on. But there is one subject

raised in his new book that I want to mention now, because it has to do with some evidence that hints at a possible existence of the Great Sphinx in the Third Dynasty, considerably earlier than the time of Cheops and Chephren. There is no doubting Chephren's passionate enthusiasm for the Sphinx, and we will be seeing evidence for that later. But it is at least a possibility that Chephren usurped the Sphinx and the Valley Temple, thereby leading us to believe falsely that he was concerned in their actual construction and creation. Usurpation of monuments was practiced by pharaohs throughout Egyptian history, and we must be alert to the possibility—and I call it only a possibility—that Chephren may have done this. Certainly, I do believe that Amenemhet II usurped the Sphinx, as we have already seen in the previous chapter. After all, there is hardly a more extreme form of usurpation than sticking your face onto something!

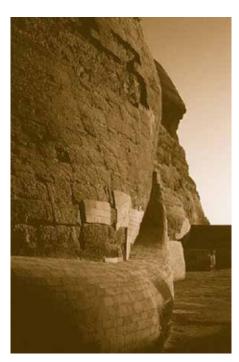

Figure 5.15. This is a photo from the right rear of the Sphinx, showing the sweeping tail made mostly of modern blocks. Above it, the superficiality of many of the inlaid modern pale stone patches is clearly visible. The large, dark and weathered blocks may be from the New Kingdom, Saite, or Ptolemaic period. In the upper left of the photo, a strange square area has been patched with small blocks at some time in the past and suggests that a chunk fell out of the Sphinx here at one time. It is behind that area that the internal tunnel extends, so its southern wall must have collapsed and fallen out, possibly during Roman times, and was replaced with the area of small blocks. Just above this square patched area, and extending along most of the rump as visible in this picture, are the oldest repair blocks of all, thought to date from the Old Kingdom. The best patches of the Sphinx were the oldest, and as time went on, the quality of the patches became worse and worse, culminating in the modern ones, which are purely cosmetic, for although the tiny modern stones have been cut with loving care and placed with great precision, the elements are too small to be robust, and they cannot possibly have a long life, but will begin dropping out and falling off within decades at the most. (*Photo by Robert Temple*)

Du Quesne points out that a boundary stela has been excavated at the site of the Step Pyramid of Zoser, who was the first pharaoh of the Third Dynasty, and that it mentions "Anubis, Foremost of the Secluded Land." The Secluded Land was a name for the necropolis, and in particular that of Giza. Later we will examine the use of this title in connection with Anubis at Giza. I mention this here because of the Third Dynasty evidence, the significance of which will become clearer in the later discussion. Du Quesne has also found at Saqqara in the Third Dynasty an inscription at a priest's tomb that refers to Anubis in the manner that was later to become familiar at Giza: "Foremost of the Secluded Land." The priest's name was Kha-Bau-Sokar, and the inscription describes him as the "Craftsman of Anubis, Foremost of the Secluded Land." There are thus two firm references, as inscriptions on stone, in the Third Dynasty to Anubis in a form that suggests (according to the discussion that is to follow) Anubis as the Great Sphinx at Giza. These references in themselves do not prove anything; they are merely suggestive. However

seriously I may take them, everyone is free to dismiss them by saying that the term "Foremost of the Secluded Land" is just a name and means nothing. It will become clear as we go on why I think otherwise.

As for the Inventory Stela that I mentioned a moment ago, we will return to it in the next chapter for information about the locality of the Sphinx, information that derives from a document that cannot be earlier than the Fifth or Sixth Dynasty, because it mentions the god Osiris so prominently. Osiris did not come to real prominence before that time. (Prior to that, his name was not Osiris, which is the Greek form of the name Asar in Egyptian, but Khenti-Amentiu, which means "Foremost of the Westerners," a name also used either for Anubis or for another form of jackal divinity. One might say, therefore, that Osiris was originally a dog!)

But for now, there are some extremely pertinent details about the Sphinx revealed in the Inventory Stela that have never received their due attention. This Inventory Stela was excavated at Giza by Auguste Mariette in the nineteenth century and is now in the Egyptian Museum at Cairo. In referring to the Sphinx, the stela nowhere describes it as having the body of a lion. Its body is not described at all, but by the time this description was written, the Sphinx had a head with a *nemes* headdress. Here is a crucial detail describing what the pharaoh did to it: "He restored the statue. . . . . He made to quarry the hind part of the nemes, which was lacking, gilded stone, and which had a length of 7 ells [3.70 meters]." 12

This bit of information is of great importance for the question of the present head of the Sphinx having been recarved from the neck of a larger head of Anubis. It suggests either that the neck was not thick enough for the full extent of the pharaoh's headdress to be carved at the back, and that it had to be added separately by a pharaoh when "restoring the statue," or that the job of recarving the neck of Anubis had been left incomplete, and he remedied this. If the present head were the original one, and had been cut from the original solid rock at the same time as the body, the full headdress would have been carved at that time, and would not have had to be added later. It is impossible now to examine these features because in the 1930s, Selim Hassan "restored" the headdress, added the lower portions of the cloth folds, or lappets, in modern concrete, and smeared modern cement around the neck and the rear of the headdress to strengthen and "improve" the structure. But if the rear of the headdress had to be added on in antiquity because it was lacking, it must have been lacking for a reason, and that reason cannot have been an oversight of the original carvers of the Sphinx. They had plenty of stone to work with, and carving the full rear of the headdress would have posed no problem to them. That the pharaoh's head lacked that element indicates clearly that either the back of the original statue's neck had been reached, and there was simply no stone left to carry the headdress any further, or the recarving was left incomplete because it would not normally be seen, so restricted was the access then to the side of the Sphinx. This textual evidence is fairly conclusive, no matter how late it is, or which pharaoh is really being referred to (we may disregard the text's description of him as Cheops). For no matter how late the text is, it is still an ancient Egyptian text, and it still preserves this structural detail. Questions of the date of the text only affect the question of the date of the recarving, not the question of the fact of the recarving. Furthermore, we can dismiss the possibility of the information being merely fabricated in antiquity, since it is such a bizarre detail for anyone to think of, with no purpose to it, that a motive for inventing it is wholly lacking.

Selim Hassan supports Gaston Maspero in his belief that the Inventory Stela was actually carved by Pharaoh Psusennes I (also known as Pasebakhaenniut I and Pasebehkanu I), of the "Tanite" Twenty-first Dynasty, who reigned 1039–991 BC according to one chronology or 1063–1037 BC according to another. They also both believe that the stela preserves older textual material, though not necessarily of the Old Kingdom date as the stela pretends. <sup>13</sup>

One curious detail relating to the rear of the Sphinx's nemes headdress is that a piece of it was found

in 1978 by Zahi Hawass. It had fallen into a hole behind the head drilled in the nineteenth century by Howard Vyse. As Mark Lehner comments in a caption in his book *The Complete Pyramids:* "When the cavity created in the back of the Sphinx [behind the head, which as a modern hole I have not bothered to discuss] by Vyse's gunpowder was cleared in 1978 under the direction of Zahi Hawass, it was found to contain not only Vyse's drill hole but also a large chunk of the Sphinx's headdress with its relief-carved pleating."<sup>14</sup>

It is probable that this loose chunk of headdress fell off the Sphinx's head with the force of the blast of the gunpowder that Howard Vyse so foolishly used on the monument, and that it was part of the additional piece added to the head by a pharaoh (whose identity we may consider uncertain, though it is likely that it was Pharaoh Thutmosis IV, of the Dream Stela that was described in chapter 3) as described in the Inventory Stela. It probably constitutes a confirmation of the information preserved in the Inventory Stela, though no one ever seems to have pointed this out before. This in turn encourages us to think that some of the information in the Inventory Stela is more ancient and valuable than it may superficially appear, though it certainly seems to be badly garbled.

With the Sphinx's body, we really have only the choice between a dog and a lion. The body has to represent one or the other, since there is no other beast that can reasonably be suggested. And if anyone were to choose between the two purely on the basis of using his or her own eyes, the choice would have to be for a dog, since the Sphinx looks like a dog and does not look like a lion. Of course, if a person is determined to be conventional, and hates more than anything in life to depart from an accepted notion, that person will never choose a dog. It is really in the end a psychological matter rather than an observational one. On purely observational grounds, anyone would have to agree that the Sphinx has no leonine characteristics but does have canine characteristics and therefore must be a dog.

One of the greatest myths of humanity is that everyone cares about the truth. Many people do not. The idea that everyone does is merely a lie told to children. There are many people who do not give a damn about the truth, because they are too busy thinking about themselves for any exterior factor, particularly an inconvenient truth, to matter. The first question that comes up when faced with an inconvenience is selfinterest: Is it to my advantage to admit that the Sphinx is not a lion, or would it make life more uncomfortable for me? The protective mutual construct that people build around themselves and share is something called *consensus reality*. They carry this around with them in the way that astronauts carry oxygen cylinders on their backs when they repair spacecraft in orbit. A person caught without his backpack is in real trouble: if a consensus reality view of something is not ready to hand, he or she may panic. This often happens at concerts and art exhibitions: What reaction is appropriate to something new? Applause? Jeering? Is it good? Is it bad? Quick, a critic must tell us! The art of political spinning is the art of constructing a consensus reality around political events so that their interpretation is manipulated within a context created by the spinner. It takes advantage of the fact that humans cannot interpret events on their own but require a context; the spinner supplies the context. This excessive timidity of humanity is what enables our species to be routinely manipulated. And as for seeing things, we see only what we are told we can see. The phenomenon of consensus blindness was discussed at length in my earlier book, The *Crystal Sun* which is basically a huge case history of the phenomenon over the ages. <sup>15</sup> This phenomenon means that people do not see what is in front of them because they believe they should not. They "censor" their optical impressions and rarely trust the evidence of their own eyes. The case of the Sphinx is a classic one of this phenomenon, which can almost be called a defining characteristic of the human race: millions of people have seen the Sphinx since it was cleared of sand, and not one until now has dared to say that it is not what it is said to be, and that it is *not a lion*. But this is just another example of the many cases I give in *The Crystal Sun* of objects on display in museums that have also been seen by millions of people, including countless "experts," but have not really been "seen" at all because they went against a consensus reality and were thus erased from consciousness. Humanity lives not in reality but in a vast collective dream. That is why heretics and original thinkers are always so persecuted, because they threaten the dream. The Sphinx for 3,400 years has been not a reality but rather a collective hallucination.

Anubis was the standard guardian of necropolises, of graves, of the dead. So it makes sense that a gigantic statue of him would have been erected at the entrance to the Giza Plateau. The Sphinx and the two adjoining temples, the Valley Temple and the Sphinx Temple, were at the very point of entry to Giza in ancient times. A quay has been excavated in front of the Valley Temple since the 1930s, which can be walked on by all tourists, and we know that at the time of the annual inundation, the water of the River Nile rose right up to that point and lapped at the entrance to the temples. One could approach by boat, alight, and enter the Land of the Dead. Of course, there has been no annual inundation since the Aswan Dam was constructed. And the course of the Nile has moved very far eastward, away from Giza, since antiquity. But old Victorian photos show the waters of the Nile nearly reaching the Sphinx circa 1900 (see figures in chapter 6), and the many early travelers' reports that I have collected and translated make clear how close one could come to the pyramids by boat in recent centuries. As I mentioned in the previous chapter, it is acknowledged that the Nile inundation rose 26 feet higher in the Middle Kingdom than it did in the nineteenth and early twentieth centuries. And as Richard Pococke recorded after his visit to Giza in the seventeenth century, the Nile at inundation then came to within "half a quarter of a mile [i.e., an eighth of a mile]" of the Sphinx, a distance of only 660 feet, or 201 meters.

This was therefore the appropriate place for Anubis to rest, guarding the entrance to the necropolis. One landed at his feet in a boat and then walked up past the Sphinx on the Chephren Causeway, or by some other route nearby one ascended the slope of the Giza Plateau from this low point. It makes no sense for a gigantic lion to sit there awaiting visitors, because it was Anubis, not a lion, who was the appropriate guardian of the dead. Lions never guarded necropolises in Egypt.

There is fascinating evidence from the Archaic Period in Egypt (the period of the First and Second Dynasties) that huge effigies of Anubis were constructed of perishable materials at least as far back as 2800 BC. This information was collected by the historian of Egyptian architecture Alexander Badawy and published in an article in a journal that Egyptologists normally do not see, The Journal of the Society of *Architectural Historians.* The only reason I was able to discover this important article was that I have been assiduously collecting everything published by Badawy for some years now due to my high opinion of him, and I have purchased portions of the libraries of several distinguished Egyptologists (Henry Fischer, Kent Weeks, etc.). Badawy gave an offprint of this article to one of them and typed the source on top (because this journal did not print it), and it was among a large pile of rare offprints that I have bought from these libraries by people such as Badawy, Hornung, and Lauer, whose work is of particular interest to me. I suspect that only a small circle of Badawy's personal friends and colleagues ever knew that he had published this article in this obscure journal. Fortunately, it came to my hands, as I would never have looked in that journal, of whose existence I was unaware. I reproduce in figures 5.16 and 5.17 the drawings made by Badawy and reproduced in the article. As all who have studied Egyptian funerary architecture know, there was a tendency to represent in stone such items as walls and other structures that were normally constructed either in mud brick or in more perishable materials such as wood, wickerwork, and reeds. This is particularly evident at the funerary complex of King Zoser (Djoser/Djeser) at Saggara, the center of which is the famous Step Pyramid. Stone was conceived of in religious terms as a kind of "freezing for eternity" of things that would otherwise perish. In the article just mentioned, Badawy discusses this practice as it applied to sacred shrines in both Egypt and India.

He discusses and illustrates the brushwood huts of a hill tribe of India called the Todas, who live in the Nilgiri hills of southern India. He points out that these huts have been reproduced in stone as Buddhist and Hindu chaityahalls (places of worship) commencing in the third and second centuries BC. It is a freak coincidence that the Toda tribe, a throwback to remote antiquity in many ways, still builds these huts of brushwood and lives in them today. By what to me is an even stranger coincidence, I myself noticed this independently as long ago as 1963, as a teenager. I entered university very young, and from the age of eighteen, all my courses were at the postgraduate level. The language I was studying then was Sanskrit, and I naturally pursued Indian studies along with that.

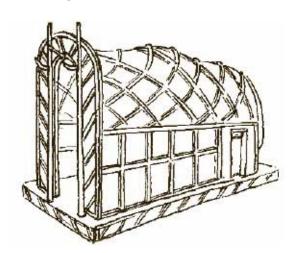

Figure 5.16. This is Alexander Badawy's perspective drawing of the Anubis hut, based on a flat view from the side of it carved in a First Dynasty depiction.

Figure 5.17. Depictions of Anubis huts from ivory labels found in First Dynasty royal tombs.

In connection with my Indian studies, I developed a particular interest in the Toda tribe. I wrote two dissertations about the Todas of modest length when I was eighteen and nineteen, in one of which I pointed out that their huts had been reproduced in stone in just the way Badawy describes. I was entirely unaware of the existence of Badawy at that time or that he had noticed this himself four years earlier. We both noticed this strange thing entirely independently. No wonder I collect papers by Badawy, as our minds obviously work in the same way. But I have only discovered our mutual observation about the Toda huts now in connection with Anubis in Egypt, which is such an unlikely way to come across it. What a strange world of crisscrossing mental threads we live in!

Figure 5.18. This is the earliest published depiction of a typical Toda hut, from the Nilgiri hills in South India. It was published in Captain Henry Harkness, *A Description of a Singular Aboriginal Race Inhabiting the Summit of the Neilgherry Hills, or Blue Mountains of Coimbatoor, in the Southern Peninsula of India*, London, 1832, opposite page 5. The hut is in the foreground at left. It is not unlike the Anubis huts seen in figures 5.16 and 5.17. (*Collection of Robert Temple*)

Badawy wrote the following about the Anubis shrines in ancient Egypt:

It needs no emphasis that symbolism played a predominant role in the religious and funerary architecture of all peoples in antiquity, and still does today. However, symbolic elements of architecture belong to an advanced stage in the development of representation. A much more primary stage is the one where the actual deity is represented architecturally as a structure formed according to his shape. This shape could be conceptual to suggest cosmic elements; for instance, the world itself as in the stupa of India, and the stretch of the horizon where the sun rises between two mountains as in the pylon of Egypt. It could also be simply realistic when it imitates the shape of an animal by which a deity is represented. Such a zoomorphic architecture may be exemplified in the so-called shrine of Anubis in Egypt.

Drawings from the Archaic Period in Egypt (2800 B.C.) represent an edicule ["little house"], probably religious or funerary, characterized by an irregular upper outline (figure 5.17). Structurally it can be described as having an irregular vault with a high arched doorway on the façade and springing from a lower vertical wall set on a shallow platform (figure 5.16). The plan is rectangular, and the possibility of its having an apsidal end is not to be excluded. The style of the representations and their date suggest that light materials such as reeds were used for the frame, and wickerwork for the walls. The structure unmistakably resembles that of a crouching animal, even to the pendent tail. I have presumed, on the grounds of a comparative study with early religious texts, that it could represent Anubis, the god of the dead, in the shape of a jackal crouching on a base. . . . . The type does not seem ever to have been translated into stone architecture. The ideological concept is that of the embodiment of a god into his zoomorphic shrine, much the same as that of the cult object of Min into his edicule. <sup>17</sup>

The same subject was referred to in passing, though in not such a way as to draw one's attention, in Badawy's classic work, *A History of Egyptian Architecture*. In volume 1 of that work, Badawy reproduces one of the Archaic drawings and says: "A series of Ist dynasty seals represent a peculiar hut, shown in front elevation with side-elevation rabated. Certain examples (from the tomb of 'Aha') convey clearly the resemblance of a crouching animal, which could be identified with the desert-hound of Anubis." 18

In other words, we have evidence in the form of pictures on seal carvings dating from the reign of King Āha, the second king of the First Dynasty, that in his day huge images of a crouching Anubis were constructed of perishable materials. Badawy ruefully observes, "The type does not seem ever to have been translated into stone architecture," and clearly expected that it should have been. What could be clearer? The Great Sphinx of Giza was that "translation into stone" of the huge Anubis shrines of the First Dynasty. The Sphinx as Anubis thus has an impeccable pedigree, going back to the very origins of high civilization in Egypt, as proved by images surviving from that time.

There is also evidence from excavations near the Sphinx to substantiate the view that the Sphinx was Anubis. In his excavations in the 1930s, Selim Hassan found a Fifth Dynasty inscription near the Sphinx that mentions Anubis, which would still have been intact at that time, but not any of the names that in later ages became fashionable for the statue, such as Hu and Horakhty. In the second line of the hieroglyphs is the figure of the recumbent Anubis. The inscription was left by a priest named Hotep, and it mentions both Anubis and the hybrid god Ptah-Sokar-Osiris, who originally was simply Sokar, the underground god of Rostau beside the Sphinx. Anubis is mentioned twice, first by his own name and then by one of his titles (Imyut), which is the name of his symbol: "A boon which the King gives, and Anubis, who is upon his Mountain [Hill], Imyut, Lord of the Land [the "Land" is the necropolis]." The king referred to is the king whom Hotep served during his lifetime, King Neferirkare (also called Kakai) of the Fifth Dynasty (who reigned 2473-2463 BC according to one chronology or 2483-2463 BC according to another). Hassan notes: "Now, the name of this King appearing in this place, coupled with the fact that the Tomb of Ra-wer, the most famous and favourite official of King Nefer-ir-ka-Ra, is situated only a stone's throw away, seems to suggest some connection between that King and the Sphinx, or its locality. Perhaps he also carried out some work around the Sphinx." But the main point for us about the inscription at this early date is that Anubis is mentioned twice in a manner that implies his obvious connection with the place, whereas none of the references typical of later New Kingdom times when the body of the Sphinx was thought to be a lion is to be found.

If we search the ancient Egyptian literature for references, we find countless ones about Anubis as guardian of the dead. The Pyramid Texts of the Old Kingdom and the Coffin Texts of the Middle Kingdom are full of references to him. Some of these are associated with descriptions of the edifices and features of that region of Giza known as either Busiris or Rostau. Busiris (in Egyptian, Djedu) was a name attached to two separate places in ancient Egypt, a town in the Delta and, as Pliny makes explicitly clear, the settlement immediately adjacent to the Sphinx Precinct that has now become the modern village of Nazlet el-Samman. Rostau is the name of the immediate precinct at Giza that was particularly sacred to the underworld god Sokar (who later became absorbed into a joint god called Sokar-Ptah-Osiris). As I explain later, in chapter 7, Rostau (which has many variant spellings, such as Rosetau, Rosetawe, etc.) appears to refer to the immediate vicinity of the Sphinx and the Valley and Sphinx Temples. The Dream Stela, the Inventory Stela, an inscription of the Saite king Psamtik II, and other sources all make clear that Rostau includes or is immediately adjacent to the Sphinx enclosure.

Hence it is of no small importance to our thesis of Anubis as the Sphinx to realize that a frequent title of Anubis was Lord of Rostau. If the Sphinx was Anubis, and was at Rostau, then to substantiate our case we need to find some ancient references to an Anubis at Rostau. And that is exactly what we find aplenty. The Egyptological scholar Terence Du Quesne has gathered many references to Anubis as Lord of Rostau in ancient inscriptions and wall carvings; he lists no less than ten published sources for these, which include many examples of the title. Certainly, a giant statue of Anubis crouching at Rostau is precisely what one would be tempted to call "Lord of Rostau." After the Fifth Dynasty, the title Lord of Rostau

began to be applied to Osiris, whereas previously the only joint claimant to the title was the underworld god Sokar, who actually resided beneath the earth at that point. Sokar and Osiris became merged into one another as Sokar-Osiris after the Fifth Dynasty. And as if that weren't enough, the neighboring god Ptah of Memphis was brought into the mix as well, so the Egyptians ended up with a trinity called Sokar-Ptah-Osiris, who then became the new Lord of Rostau. But certainly in the beginning it was only Sokar and Anubis who were Lords of Rostau: Sokar because he lived underground at that spot and Anubis because he crouched on the surface as the site's guardian. And we have plentiful textual evidence as well as inscriptions.

In the Coffin Text Spell 241, Anubis is mentioned in the same breath as Rostau; the deceased, who identifies himself with Osiris, is speaking: "I am Osiris and I have come to Rosetau in order to know the secret of the Dat [Duat; netherworld], to which Anubis has been initiated."<sup>22</sup>

Particular attention has also been drawn to this passage by Terence Du Quesne, who has written several further studies of Anubis and the jackal. His 1991 book *Jackal at the Shaman's Gate* bears the subtitle "A Study of Anubis, Lord of Ro-Setawe" (Rostau).<sup>23</sup> In this book he speaks of "the gate, called by the Egyptians Ro-Setawe" and quotes a Middle Kingdom text referring to it and specifying that Anubis is to be found there:

In the *Book of the One in the Netherworld*, there exists a strange corridor, the "land of Sokar," between the chambers of the third and fourth hours of the night, through which the justified soul must travel in order to reach the dawn. Its explanatory text is unequivocal:

The secret ways of Ro-Setawe
The gate of the gods
Only one whose voice is heard
May pass them . . .
The secret way to which (only) Anubis has access
In order to conceal the body of Osiris.

Anubis, god of embalmment and reviver of the original Osiris, conceals the body of the justified person, who is identified with Osiris, in order to breathe life back into it. Here is the bridge between death and rebirth. . . . Two passages in the *Coffin Texts* are similarly explicit:

I have come . . . to enter the secret gateway By which Anubis is initiated. I have come to Ro-Setawe In order to know the Mysteries of the Netherworld Into which Anubis is initiated.

It should be understood that the divine king identifies himself with Anubis as all justified souls [those good people who are worthy to live eternally, and escape annihilation] do with Osiris later in Egyptian history. . . . Anubis is often given the title Lord of Ro-Setawe [Rostau]. One spell in the Coffin Texts is entitled "Invocation for Entering the Gate of the Netherworld" and has the justified person declaring: "I have come in order to enter the gateway that is protected by Anubis." . . . One of Anubis's most appropriate attributions is "Master of Secrets" . . . and the pharaoh Cheops in later times himself received the epithet of "Master of Secrets in Ro-Setawe." . . . The local deity of

Memphis is Sokar, whose name survives in "Saqqara." From early times Sokar is "lord of Ro-Setawe," an epithet also given to Anubis. . . . In many representations, the Anubis jackal is shown couchant on a funerary chest or box known as the "sacred casket." . . . This is in his capacity as "Master of Secrets." This container may be seen as a kind of Pandora's box which is the symbolic entrance-way to Ro-Setawe.<sup>24</sup>

We can see that there are many passages in ancient Egyptian texts that locate Anubis at Rostau (which Du Quesne prefers to spell Ro-Setawe, both variant spellings being technically correct), which is at Giza and is believed to be that part of Giza where the Sphinx is found. The problem noted earlier that there are "no references" to the Sphinx in the ancient Egyptian literature is immediately remedied if we assume that the Sphinx was a giant statue of Anubis, for then we are positively deluged with references in ancient Egyptian literature. And one of the passages just quoted actually describes the gate at Rostau as being protected by Anubis.

Anubis is often described in the texts as "presiding over the Pure Land," which means the necropolis, and which is one of the names of the Giza Plateau. The Gate of Geb (the Earth god), or the Doors of Geb, was located at Rostau, at the feet of Giza. In the Pyramid Text Utterance 437, we read of Anubis "on his baldachin" at the Doors of Geb. "Baldachin" is the translation often given by Egyptologists to the Egyptian word for the strange shrine on top of which Anubis is usually portrayed stretched out on his belly. Anubis is seen crouching on top of it in figure 5.9. This is what Du Quesne perhaps more sensibly calls a funerary chest. Since *baldachin* is not a word any of us uses in daily conversation, I thought I ought to quote its definition as given in the *Shorter Oxford English Dictionary:* "A structure in the form of a canopy, either borne on columns, suspended from the roof, or projecting from the wall, placed above an altar, throne, or doorway."<sup>25</sup>

From this we may see that "baldachin" is not entirely satisfactory as a translation for a solid structure, but as the Egyptologists insist on using it, we need to know its meaning if we are to understand their translations as they relate to Anubis.

In the Pyramid Texts Utterance 437, we read of the risen soul: "You arise as Anubis who is on the baldachin." <sup>26</sup>

This appears to refer to the resurrected deceased still recumbent on his death-couch, as we see so often in the depictions of Osiris. The recumbent Anubis is therefore to be taken as symbolic of the prostrate but yet living dead. In fact, the god of Rostau, Sokar, is often depicted lying on a bier, perhaps in imitation of the recumbent Anubis. I reproduce an ancient depiction of this eerie scene in figure 8.38, where Sokar is replaced by his successor, Osiris.

Anubis is further described in the same text as "Anubis who presides over the Pure Land," in other words, the necropolis. In Pyramid Text Utterance 581, instead of "the Pure Land," it is "the Sacred Land" over which Anubis presides. These are alternative ways of describing the necropolis. Another form that we have already encountered is "the Secluded Land." These "Lands" are all the same. And one inevitably wonders, if Anubis is "presiding" over the necropolis, how is he doing so? In other words, is he present? Is he represented? To crouch as guardian at the entrance to the necropolis is indeed to "preside" over it.

A description is also given in Utterance 437 of the dramatic events that the risen soul encounters at Rostau, where the gates or Doors of Geb are to be found: "The earth speaks: The doors of the earth-god are opened for you, the doors of Geb are thrown open for you, you come forth at the voice of Anubis, he makes a spirit of you." 28

If perhaps the gigantic statue of Anubis, now known as the Sphinx, is what is referred to here, perhaps he did "speak" and deliver pronouncements when he was Anubis, just as verbal tradition maintained in much later centuries that the Sphinx, by then with a pharaoh's head, often did. For the tradition is persistent that the Sphinx "spoke," and a speaking tube, tunnel, or simply a projected voice might well have been employed by the priests in the earliest times. Thus there may well have been a physical "voice of Anubis" at ceremonies.

The ancient descriptions of a *couchant* Anubis are so incredibly precise, in fact, that Pyramid Text Utterance 659 describes a recumbent Anubis as being *beside a causeway*. And as we know, the Sphinx is indeed beside what we now call the Causeway of Chephren: "You have descended as a jackal of Upper Egypt [a description of the type of jackal, not of its location in this text, which suggests that these wild dogs came from there], as Anubis on his baldachin. May you stand up at the causeway [as Geb] who presides."<sup>29</sup>

Pyramid Text 677 has an intriguing description of the recumbent Anubis: "O King, your shape is hidden like that of Anubis on his belly; receive your jackal-face and raise yourself, stand up." 30

"Receive your jackal-face" refers to the common practice of the donning of a jackal mask (see figure 5.19). Many of the jackal-headed figures seen in Egyptian wall carvings are of priests with jackal masks and are not intended to represent Anubis himself. A very clear depiction of a priest wearing a jackal mask is known from the Temple of Denderah, where in an instance of "transparency of depiction," the priest is shown with his own face and superimposed over his face is the head of Anubis (with his eye holes being in Anubis's neck). A clay mask of Anubis with eye holes in the neck is actually preserved in the Hildesheim Museum in Germany and was tried on by Arelene Wolinski, who said "it fitted comfortably over her head and rested on her shoulders and back. The two holes in the jackal's neck turned out to be just at the right spot for eye holes, thus confirming the accuracy of the Denderah relief."31 An older animal mask dating from the Middle Kingdom also survives, "in the form of a grotesque lion's head, and was found at Kahun . . . This object shows signs of wear, indicating that it was in frequent use." This was discussed by Terence Du Quesne in his lengthy article about ritual Egyptian masks published in 2001, which culminates with his description of getting a modern puppet maker to fabricate an Anubis mask, of which he says that "the process of creating the mask took the equivalent of about five weeks of full-time work." Du Quesne says the mask weighed about 1.1 kg and "adds about 45 cm to one's height," and the effort was very successful at replicating a usable Anubis mask as depicted in ancient Egyptian art. 32

The strange feature of the Pyramid Text's description of the recumbent Anubis that has just been quoted is the comment that his shape is "hidden." What can this mean? I believe this is a specific reference to the Sphinx, but to make clear how it applies to the Sphinx, I need to move on to the next idea about what the Sphinx was originally like, which is in the next chapter. There we shall see that part of the body of Anubis may well have been obscured and "hidden" during the Old Kingdom, in a way that once again accords with much textual evidence.

Figure 5.19. Anubis not only guarded the dead; he was also the god of embalming. Here he is seen ministering to the king's mummy. Beneath the lion-footed table on which the royal mummy rests are the four jars containing the viscera of the deceased pharaoh. These are discussed in chapter 6, where their part in a ceremony beside Jackal Lake is discussed. This illustration appeared in Villiers Stuart, *Nile Gleanings*, John Murray, London, 1879, plate 23, opposite page 194.

The book by Du Quesne, *The Jackal Divinities of Egypt*, presents a large amount of crucial information about Anubis at Giza, and what is revealed by this is most remarkable and highly relevant to our subject. There was certainly something of an obsession with extra-large Anubis figures at Giza during the Fourth Dynasty, which is the dynasty of Cheops and Chephren.

Du Quesne calls attention to a considerable number of hieroglyphic inscriptions from Giza during the Fourth Dynasty that contain giant pictures of Anubis. These large Anubis pictures completely dwarf the surrounding hieroglyphics, while acting as a hieroglyphic sign simultaneously with being illustrative. As far as I know, this phenomenon has not otherwise occurred in Egyptian hieroglyphic inscriptions either before or since that time. It is therefore highly important, and so far has had no explanation other than whimsy. Here are the comments Du Quesne makes about the four Giza tomb inscriptions, which he designates III.A7, III.A8, III.A9, and III.A10: "showing couchant jackal . . . depicted very large," "with disproportionately large representations of couchant jackal," "large isolated figure of couchant jackal, facing right," and "disproportionately large representations of couchant jackal." These Anubis figures really do dwarf everything else. I reproduce examples in figures 5.20 to 5.23. Du Quesne says of these huge jackals in the midst of normal inscriptions:

L. Holden associates [a jackal statue found at Giza] with a small genre of tomb reliefs of the period which show, in the offering formula, greatly enlarged jackal figures. . . . The earliest . . . has the jackal many times larger than the accompanying signs. . . . In a few cases, similarly enlarged jackals are encountered on sarcophagus lids of the period. . . . These early Anubis representations in the formula of offerings have some intriguing features. They seem to originate in Giza, in the family of the great pyramid-building kings of Dynasty IV . . . the eldest son of Cheops, . . . his son and vizier . . . his daughter . . . [and] Chephren's queen. We may assume that the size of the Anubis figures was designed to emphasize the importance of the god in protecting the tombs' royal occupants in the netherworld. Such images might also have reinforced the kings' funerary cult. 34

So we have "supersized" images of Anubis in these royal tomb inscriptions dwarfing everything that is near it or around it. It is wholly out of character for Egyptian art for there to be such outlandish

"supersized" Anubises. The Egyptians were fanatical about keeping everything in correct proportion. So why were these images of Anubis enlarged to such gigantic size in a way that no other god in the entire history of Egypt ever was? Reinforcing a funerary cult is not a good enough explanation. Neither is protecting the royals in the netherworld. That would not explain the giant Anubises. The Egyptians just didn't do things like that. Furthermore, we cannot even assume propaganda as a purpose, since these were tomb inscriptions, which few people would ever see. So what was the purpose? What if the giant Anubises were intended to represent a giant Anubis that actually existed? Wouldn't that make sense? What if they were actual pictures of the largest Anubis in Egypt, the Great Sphinx of Giza?

Five of the most impressive of the supersized Anubises were found in three of the most prominent of the tombs (mastabas) of the Eastern Cemetery at Giza. Both of them are in the "front row" just east of the three little pyramids known as "queens' pyramids" that stand immediately southeast of the Great Pyramid. Some people like to have "front-row seats" at the theater. But these are "front-row tombs," sure to be of use when you are dead! (That way, do you get to see the gods better?) The first of the front-row tombs for us to consider is that of Prince Khafkhufu, a younger son of Cheops (Khufu). Khafkhufu was Controller of the Palace, Sole Companion to the King, and Priest of the Souls of Nekhen (the "souls of the south"). He was given one of the most important mastaba (aboveground) tombs at Giza. Here is how William Kelly Simpson describes it: "The mastaba of Khafkhufu I and his wife is one of the two great double mastabas in the row nearest the great pyramid in the eastern cemetery, situated south of the pyramid causeway and east of the three queens' pyramids."<sup>35</sup>

Figure 5.20. Drawing (left) of the inscription on the northern doorjamb (right) of the tomb chapel of Prince Khafkhufu I at Giza. (From Dunham Dows and William Kelly Simpson, The Mastabas of Kawab, Khafkhufu I and II, Boston, 1978)

Figure 5.21. Drawing (left) of the inscription on the southern doorjamb (right) of the tomb chapel of Prince Khafkhufu I at Giza. (From Dows and Simpson, Kawab and Khafkhufu)

Figure 5.22. Drawing (left) of the northern doorjamb (right) of the tomb chapel of Queen Mersyankh III at Giza. (*From William Kelly Simpson*, The Mastaba of Queen Merysankh III, *Boston*, 1974)

Figure 5.23. Drawing (left) of the southern doorjamb (right) of the tomb chapel of Queen Mersyankh III, wife of King Chephren, in her mastaba at Giza. (*From Simpson*, Merysankh III)

Supersized Anubises were carved on the two opposite entrance jambs of the southern chapel of this mastaba tomb. On top of them, at one time, had stood part of the Temple of Isis, which was built at a later epoch. These two Anubises are shown in figures 5.20 and 5.21. Beneath both is a king's name in an ellipsoidal cartouche: that king is Cheops (Khufu), the father of the prince and reputed builder of the Great Pyramid at whose foot this tomb stands. These huge Anubises function as a hieroglyph in each inscription, but at the same time stand out as the prime pictorial element. The inscription of the northern picture says: "A boon which Anubis, foremost of the necropolis, gives, (namely) a good old age before the great god (for) the king's son Khafkhufu." The southern inscription says: "A boon which Anubis, he who is in W[et], [this archaic place name, also spelled Ut, has among its meanings "hole," as well as being the second half of Imiut, a title of Anubis and the name of his fetish symbol, the whole of which name could be taken to have the meaning of "the inside of the hole," thus possibly being a reference to the Sphinx Pit: Anubis being "in Wet" thus potentially meaning Anubis being "in the Pit"] gives, (namely) power and nobility before the great god (for) the king's son Khafkhufu."

These huge pictures of Anubis were thus incorporated into inscriptions that called upon Anubis to grant the soul of Khafkhufu power, nobility, and "a good old age" in the afterlife. Anubis was to grant these things to the prince through his position as Foremost of the Necropolis, that is, the chief deity of

Giza. The inference that Anubis as the Sphinx was the chief presiding deity referred to is hard to resist, as is the supposition that the pictures were meant to refer to his giant statue nearby.

The eldest brother of Khafkhufu also had at least one giant Anubis in his tomb, which can be seen in figure 5.24. He may have had more, but his tomb has been greatly destroyed. This was Prince Kawab, who should have become pharaoh after the death of Cheops, but as he died just before becoming king, his other brother Djedefre (also known as Rededef, or Radjedef, who, it has been suggested, may have murdered Kawab to secure the succession for himself) became pharaoh instead (though he built no pyramid at Giza), and Djedefre was in turn succeeded by Chephren. Simpson decribes Prince Kawab's mastaba tomb as follows: "Prince Kawab, the eldest son of Cheops, was buried in the large double mastaba on the east side of the pyramid of Cheops in the first row of mastabas nearest the pyramid, just south of the pyramid causeway and east of the northernmost of the three queens' pyramids. By its position it is singled out as the pre-eminent mastaba in the eastern cemetery." 37

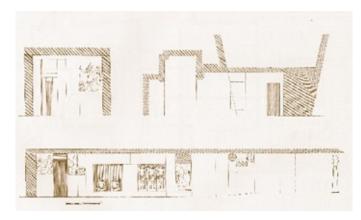

Figure 5.24. Plan and section of the tomb of Prince Kawab at Giza. In the bottom half, to the right of center at the top of the wall beside which the granite sarcophagus (not shown) of the prince would have rested, is one of the inscriptions with a supersized Anubis. (*From Dows and Simpson*, Kawab and Khafkhufu)

Three surviving inscriptions showing the supersized Anubis were carved just above Prince Kawab's granite sarcophagus and read:

(1) A boon which the king gives and Anubis, foremost of the divine booth, a burial in the necropolis as a possessor of a well provided state before the great god, officiant of Anubis, priest of Selket, Kawab; (2) a boon which the king gives and Anubis, foremost of the divine booth, a burial in the necropolis in the western cemetery [this is an interesting detail, because it shows that what we call the Eastern Cemetery because it is east of the Great Pyramid was called by the Old Kingdom Egyptians the western cemetery because it was west of the Sphinx], having grown gracefully old, the king's son of his body, Kawab; (3) king's eldest son of his body, officiant of Anubis, Kawab. 38

It is interesting to learn that the eldest son of Cheops and crown prince held as his chief position "Officiant [Chief Priest] of Anubis." One might well wonder what this could possibly mean, and how such duties could conceivably be carried out, since there was no temple of Anubis or even any known cult center of Anubis where one could officiate as a priest. All these problems dissolve when one realizes that Anubis was just a few minutes' walk down the hill, and was the Sphinx. In fact, the ceremonies at which the eldest son of the deceased pharaoh was required to preside after his father's death took place at the Sphinx, and are described in the next chapter, from texts found among the Pyramid Texts of the succeeding dynasty. (I should mention in passing that it has been suggested that Kawab and Chephren were really the same person, and that the tomb of Kawab was built for Chephren before he became king, after which he

changed his name. However, this is only speculation, and is also very confusing to us.)

The other front-row mastaba to consider is that of Queen Mersyankh III, who was the granddaughter of Cheops, some say the widow of her uncle Prince Kawab, definitely the daughter of her aunt and sister-in-law, who was wife of King Djedefre (or Rededef/Radjedef), niece and sister-in-law of King Djedefre, and queen of her brother-in-law and uncle, King Chephren. She was also Priestess of Thoth, to whom she was not related. (That's a joke, just in case you are too dazed by all these incestuous relationships to realize it.) The two supersized Anubises in this queen's tomb were carved as part of inscriptions in the northern and southern jambs of the entrance to the tomb chapel, which is the best-preserved tomb chapel in the entire Eastern Cemetery (or as she would have said, the western cemetery). They are shown in figures 5.20 to 5.23. On the north doorjamb, the inscription reads: "A boon [a gift] which the king gives and Anubis foremost of the divine booth to a spirit who is noble in the sight of the great god, lord of the desert. Beholder of Horus and Seth, King's daughter, greatly praised, King's wife, Mersyankh."

On the southern doorjamb, the inscription reads:

A boon which the king gives and Anubis, he who is in Wet, lord of the necropolis, to a spirit who is noble in the sight of the great god, lord of the necropolis. Beholder of Horus and Seth, great favourite, companion of Horus beloved of him, follower of Horus, King's wife, King's daughter, Mersyankh. 39

We should note that Anubis is called twice not only the Lord of the Necropolis here but also Lord of the Desert, and once again is referred to as "the great god." The eternal gifts are given to the deceased in these inscriptions jointly by the pharaoh and by Anubis. The inference that the Sphinx as Anubis is being referred to becomes increasingly strong. As I have already mentioned, the supersized Anubis functions also as a hieroglyph in the inscriptions. Where it does so is in the actual appearance of the name Anubis in each of the inscriptions quoted in translation above. In other words, what the inscriptions really say is, to take one example: "A boon which the king gives and [supersized picture of Anubis] foremost . . ." and so forth. Anubis is not spelled out; it is shown by the giant picture. What all the inscriptions might therefore be saying is that the boons are given by the king and by the Sphinx, understood to be the supersized statue of Anubis presiding over the desert necropolis, or, as we might lightheartedly call him, Anubis Magnus.

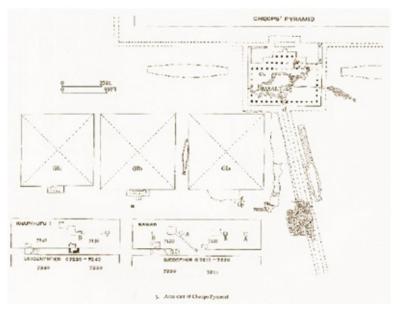

Figure 5.25. The mastabas of Prince Khafkhufu (left) and Prince Kawab (right) are shown here on this plan from William Kelly Simpson, at the bottom of the picture. Above them are the three mini-pyramids known as the queens' pyramids. At the top of the

picture is the southeast corner of the Great Pyramid of Cheops. The strange oblong shapes are boat pits, where wooden boats were once buried for use in sailing the celestial seas of the other world. At the foot of the Great Pyramid was the Funerary Temple of Cheops, now entirely gone except for part of its magnificent and beautiful basalt floor. Leading down from the site of the Funerary Temple we see the commencement of the now vanished Cheops Causeway, with a long boat pit beside it. It bends at an angle to the north, whereas the Chephren Causeway bends at an angle to the south. The strangest feature of the Cheops Causeway is that it went to the edge of the cliff and plunged off it and then continued below! Part of its further course may be seen in the old plan in figure 6.12, drawn before houses crept up to the edge of the Giza Plateau. We now know that this Cheops Causeway culminated in the Valley Temple of Cheops, on top of the ruins of which at the moment sits a private house. Since the man who lives there is a prominent resident of Nazlet el-Samman whom no one wishes to offend, nothing has been done about gently suggesting to him that he might go house hunting. It is hard to imagine what could be more important currently than excavating the Valley Temple of the man who is supposed to have built the Great Pyramid, but then c'est la vie égyptienne. (Figure 3 in Willam Kelly Simpson, The Mastabas of Kawab and Khafkhufu I and II, Boston, 1978)

Anubis was especially honored by Fourth Dynasty pharaohs in another way as well. In the ruined

Valley Temple of Mycerinus (the pharaoh whose name has been attached to the smallest of the three Giza pyramids), archaeologists found the remains of a green statue of Anubis, said to be made of "green basalt" (whatever that is!) or otherwise of green "diorite" (whatever that is!), though I suspect that, as usual, the Egyptologists, who generally know little about mineralogy, have given a wrong identification of the stone, or should I say two wrong identifications. It is probably a stone called by the Egyptians *bekhen* and is a graywhacke, or mudstone, containing chlorite, which makes it look green. This statue was of an Anubis *couchant*, in other words, a miniature replica of what I believe to have been the original form of the Great Sphinx of Giza. This statue was a foot high and nearly 2 feet long. It is preserved in the Boston Museum of Fine Arts. Du Quesne says it "is probably the earliest extant example of a figure of the Anubis jackal in its canonical form. . . . Perhaps the earliest three-dimensional jackal figure extant." I would suggest that, in addition, it is possibly the only surviving three-dimensional replica of the original form of the Sphinx. It is not complete, but enough of it survives for us to be certain that it represents the standard form of the recumbent jackal lying on its belly with its paws stretched out in front of it.

There are many mentions of Anubis in inscriptions in tombs at Giza besides the royal ones of the Fourth Dynasty that were given above. These tend to use more or less the same formulas, describing Anubis as Lord of the Necropolis who gives a boon to the deceased and so forth. However, there is no need to survey the whole of the tomb inscriptions of the Giza Plateau, as the point has been sufficiently made. See figure 5.26.

Another feature of Anubis that is continually mentioned throughout Egyptian history is that he is associated with a hill or mountain. This hill or mountain is never specified precisely, and one gets the impression that we are meant to be familiar with the reference without any need for explanation. Anubis is often called "Anubis on his hill" or "Anubis on his mountain." Most Egyptologists use the translation "hill" instead of "mountain," as it is not thought that an actual high mountain is intended, and there is no evidence of any kind to associate Anubis with a real mountain. Strangely enough, in the earliest texts, namely the Pyramid Texts, this epithet does not occur. Because so little has been written about Anubis, it seems that no one has searched the Pyramid Text references to Anubis before now to check this. It is rather odd that this description of "Anubis on his hill," which is so common for thousands of years afterward, is absent from the earliest texts, which are nevertheless full of references to Anubis, generally describing him as being recumbent, presiding over the Pure Land or the Sacred Land, and being "on his baldachin." It is as if at the time of the Fourth Dynasty, as well as in the Pyramid Texts (Fifth and Sixth Dynasties, circa 2500–2200 BC), there was no need to mention that Anubis was associated with a hill, but merely to stress his position as guardian of the necropolis. Later, it seemed important to associate Anubis with a hill. And I believe that this was because the center of gravity of the pharaoh's court had moved away from Memphis, so that it was necessary to call to mind the fact—previously unavoidable and

known to all who mattered—that Anubis was to be found at the Giza Plateau, the plateau being, of course, a hill. For those who had moved away from Memphis, it was just as well for them to remember that Anubis guarded the entry to the most famous hill in Egypt. When everyone was living beside it, it was merely called the necropolis, that is, the Pure Land or the Sacred Land. But when people were no longer beside it, it was recalled to mind as *the hill*.

Figure 5.26. This fragment of a stone carving shows a portion of an inscription featuring a recumbent Anubis lying on his belly in the same position as the Sphinx. The inscription shows the hieroglyph *hotep* beneath Anubis (whose Egyptian name was Anpu) so that the reference is to the personal name Anpu-hotep, meaning Anubis Is at Peace, which was used by high priests of the period between the First and Third Dynasties, a period prior to the conventional date of carving of the Great Sphinx. The fragment was excavated in the season 1922–1923 at the site of Abu Ruash, a hill that overlooks Giza, by French archaeologists. It was found at the entrance to the underground site, hypogeum H-9. It is plate XVIII, number 4, in M. F. Bisson de la Roque, *Rapport sur les fouilles d'Abou Roasch* (1922–1923), in *Fouilles de l'Institut Français d'Archéologie Orientale de Caire* (Années 1921–1923), Cairo, 1924. See also the text discussion of the find on page 62 of that volume. (*Collection of Robert Temple*)

"Anubis on his hill" therefore became, I believe, the standard way of referring to the Great Sphinx of Giza. The phrase seems to have occurred for the first time in the Fifth and Sixth Dynasties, after the Pyramid Age and as the Old Kingdom was drawing to an end.  $\frac{42}{2}$  The Egyptian expression "he who is on his hill" is tepidjuf. Du Quesne suggests that this title "has no direct funerary associations, and is usually taken to refer to the natural desert habitat of the jackal, and to the rugged terrain of the necropolis." I would say that this is near to the truth, for the "hill" is clearly the Giza Plateau, which is indeed rugged and a desert, and, above all, is a hill. I believe that "Anubis on his hill" is synonymous with "the Sphinx of Giza." In fact, the word dju (hill) also means necropolis, as does tep-dju. And a tepi-dju is also a "necropolis official." Therefore, the very same words that mean "he who is on his hill" also mean "necropolis official" or "necropolis head." The epithet "he who is on his hill," as applied to Anubis, therefore always had the double meaning of "he who is at the head of the necropolis," that is, at Giza. It seems clear that only the Sphinx can be referred to.

In the Middle Kingdom (2119–1793 BC according to one chronology; circa 2000–circa 1750 BC according to another), the texts known as the Coffin Texts are found in coffins of the period. They were not intended to be read by anyone but the deceased and the gods, as they were inside the coffins in the form of protective spells. But they reveal much mythological and religious lore, and some of it is derived from the earlier Pyramid Texts. In Spell 825, a Spell for Entering the Netherworld, we are specifically told by the deceased that he has entered its "gate which is under the care of Anubis." Since the gate to the netherworld was at Rostau, the expression that the gate was "under the care of Anubis" is another interesting reference that appears to apply to the physical presence of Anubis as official guardian of

Rostau at Giza.

In Spell 629, Anubis is described as being in Djedu (i.e., Busiris, now Nazlet el-Samman), which is where Rostau is situated (Rostau being a more restricted portion or precinct of Djedu). He is also there called Lord of the Desert, which is unusually specific, in that his "Land" is generally called, by a religious euphemism, either the Pure Land or the Sacred Land, but here the scribe slips and specifies that it is in the desert, as Giza indeed is. Djedu and Rostau are mentioned together in Spell 314, where the "secret thing" and the "mysteries" of the god Osiris (originally those of the god Sokar) are given the specific physical description of being in "the deep place in Rostau," obviously a reference to a deep underground location there. Although many ancient texts refer to underground caverns and chambers and tunnels at Rostau, it is rare to find a more physically specific description referring to "the deep place." There can hardly be any doubt, from the many textual references, that Rostau contains vast underground constructions, many being expanded natural cavities in the limestone.

I shall have much more to say about this in the future, as the underground complex at Rostau, near the Sphinx, is a subject concerning which discussion has only just begun, and it goes far beyond the scope of this book, the limited purpose of which is to establish the truth about the Sphinx as a preliminary step to carrying forward the discussion of what else was really going on at Giza in the period before the Fifth Dynasty. Much of the further discussion is found in my next book, *Egyptian Dawn*. However, a partial indication of that subject is also found in the next chapter, which re-creates one of the most important ceremonial purposes of Giza in the early days, before the true tradition decayed and became merely a memory. It is necessary to establish this crucial ceremonial tradition clearly for the record, since until it is grasped, further discussion of Giza cannot proceed. After all, the Sphinx stands guard over the necropolis not only in a physical sense but in an intellectual sense as well: failure to comprehend its true purpose blocks all further progress by the inquirer, and the problem of the Sphinx thus acts as a guardian and an obstacle to understanding anything else stemming from that period. You have to grapple with the Sphinx first and solve its riddle, just as Oedipus did in Greek myth, before you can avoid being devoured and can go on to *enter the true city*.

## SPHINX ISLAND

During the 1990s, the general public in many parts of the world was subjected to a massive wave of publicity and marketing relating to the Sphinx. This was principally generated by the books and TV documentaries of three popular writers who agreed about one thing: the Sphinx was at least 12,500 years old because there was evidence of water erosion in the Sphinx Pit, and this must have been caused by "ancient rain" circa 10,000 BC, when Egypt was believed to have had a different climate than it has today. Although I agree that there is evidence of water erosion in the Sphinx Pit, I reject these ideas, believing this can be explained in a new way. Through constant and insistent repetition, like some sort of hypnotic mantra, by means of books, conferences, and television, the idea that the Sphinx is at least 12,500 years old seems to have hardened into a kind of dogma to such an extent that among "alternative" audiences, anyone who does not accept it can even be presumed to be part of an orthodox conspiracy to suppress the truth.

By a strange quirk of fate, I became directly involved in this odd story of the "ancient rain" theory of the Sphinx at a very early stage. The observation that there appeared to be water erosion on the Sphinx itself (no mention was made of the Sphinx Pit) was first made by the Egyptological scholar Schwaller de Lubicz in a book published in French in 1961, where it was mentioned only in passing as an enigmatic feature. The book was called *Le Roi de la théocracie pharaonique* (*The King of Pharaonic Theocracy*). An English translation was eventually published in 1982 under the title *Sacred Science: The King of Pharaonic Theocracy*. In this book, Schwaller de Lubicz mentions, in the midst of a general discussion of the Sphinx, "that Sphinx whose leonine body, except for the head, shows indisputable signs of aquatic erosion." He added a footnote that stated further: "It is maintained that this erosion was wrought by desert sands, but the entire body of the Sphinx is protected from all desert winds coming from the West, the only winds that could effect erosion. Only the head protrudes from this hollow, and it shows no signs of erosion."

Indeed, the neck used to show extreme signs of erosion (see figures 6.1, 6.2, and 6.3, and figure 6.6) until it was strengthened in modern times by cement and concrete. As Zahi Hawass, secretary general of the Supreme Council of Antiquities of Egypt, has said: "Baraize restored the head with cement, for at that time it was deemed necessary for the protection of the head. . . . The cement restoration of the head is not good and obscures the impressiveness of the Sphinx. Therefore, one suggests that Baraize's restoration of the head be reversed." At the moment, the head is relatively free of signs of erosion, which is partially due to the fact that it was recarved by Pharaoh Amenemhat II and is thus much younger than the rest of the exterior of the Sphinx, and also because the stone of that part of the Sphinx is much stronger, as it comes

from a stronger stratum of the natural rock. Also, the face of the Sphinx that we now see is not the face that was seen in, say, 1900. In figures 6.4, 6.5, and 6.6, photos taken in the 1870s and 1880s, a huge gash can be seen in the upper left side of the Sphinx's face. This is one of many blemishes filled in with cement by Baraize in the 1920s, when he took as much care over the Sphinx's face as a plastic surgeon might with a modern film actress. The only thing the Sphinx hasn't had by now is Botox. But Schwaller de Lubicz's point certainly merits investigation.

Apparently the first person to take Schwaller de Lubicz's comments seriously and to investigate them further was an American, John Anthony West, in the late 1970s. This is when I unexpectedly became involved. Between 1978 and 1980, my friend Randall Fitzgerald and I jointly edited a magazine dealing with the frontiers of science and knowledge called Second Look. We worked very happily together as editors and had a model collaboration; we never had any disagreement that I can remember, so the recollections are very pleasant. Our interests did not wholly coincide, as Randy was keen on some things that did not particularly interest me, and I was more interested in advanced theories in physics. We published the first popular articles anywhere on such subjects as twistor theory and the multiple-universes interpretation of quantum mechanics (which I wrote jointly with Roger Penrose and David Deutsch, respectively). Suddenly, out of the blue, one of our readers submitted an unsolicited article about ancient Egypt. His name was John Anthony West, and the article was entitled "Metaphysics by Design: Harmony and Proportion in Ancient Egypt." I enthusiastically agreed to publish this article because I thought such things needed airing, the article was fascinating, and the matters it discussed were of the greatest possible interest, although I disagreed with West's ideas of Atlantis and his notion that the Sphinx was more than 12,500 years old. However, as editors, we made it our policy not to allow personal disagreements with the opinions of authors to influence our decisions about publishing their ideas. The article duly appeared in our issue for June 1979. Some months later, West brought out a book carrying his arguments much further, entitled *Serpent in the Sky*. <sup>5</sup> By this chain of events, without agreeing with him, Randall and I thus became the first publishers of West's ideas that the Sphinx was of immense antiquity, far older than the archaeological record could possibly justify. Schwaller's observation about water erosion is a fundamental one that needed attention, and who is to say that anyone would ever have called vociferous attention to it if West had not done so? When I first met West in the 1990s, he said he had forgotten about the article he did for our magazine and that he had no copy of it, so I was able to send him one for his files.

Figure 6.1. This photo dating from circa 1860–80 shows the extreme neck erosion of the Sphinx before it was "restored." (Collection of Robert Temple)

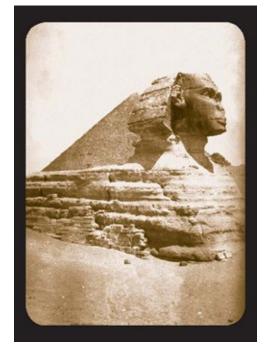

Figure 6.2. This photo, taken probably in the 1920s, shows the neck erosion of the Sphinx and the curiously pathetic attempt to fill holes in the right (southern) side of the Sphinx with stone blocks. They may have been covering an entrance into the Sphinx's body near one of the southern cupolas, or these blocks may merely be filling unsightly hollows. However, they were clearly intended to cover something, whether cosmetically or otherwise. This evidence should be taken into consideration when trying to decide whether the cupolas block an entrance to the body of the Sphinx. (*Collection of Robert Temple*)

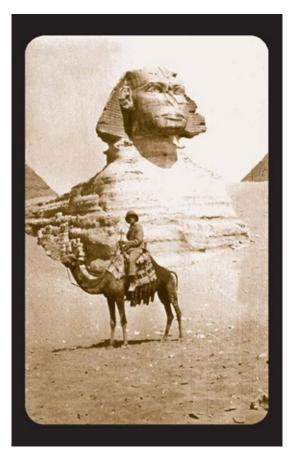

Figure 6.3. This photo of a European soldier on a camel, probably in the 1920s, shows the same neck erosion and stone blocks on the southern flank of the Sphinx as we saw in figure 6.2; the photos were probably taken on the same day as part of this man's tourist visit. (*Collection of Robert Temple*)

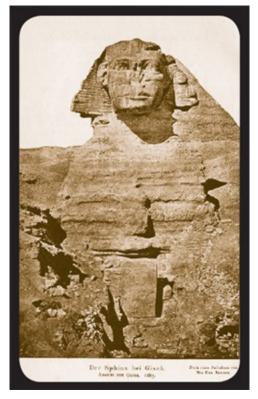

Figure 6.4. A photo taken of the Sphinx in 1893 by Emil Brugsch, showing the gash in the Sphinx's left forehead. (*Collection of Robert Temple*)

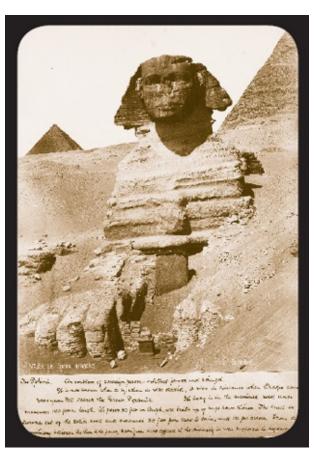

Figure 6.5. A photo of the Sphinx by G. Sarolides, probably from the 1870s. The altar where offerings were made sits in front of the chapel between the paws. This photo shows clearly the huge gash in the Sphinx's left forehead and the stump of the left lappet of the headdress. The original caption, written by hand, says: "The Sphinx. An emblem of sovereign power—intellect joined with strength. It is not known when or by whom it was erected, it was in existence when Cheops some 3000 years BC reared the Great Pyramid. Its body is in the natural rock and measures 140 feet in length. Its paws 50 feet in length, are built up of huge hewn stones. The head is carved out of the solid rock and measures 30 feet from brow to chin, and 14 feet across. From a sanctuary between the lion like paws, sacrifices were offered to the divinity it was supposed to represent." (Collection of Robert Temple)

Figure 6.6. A glass lantern slide circa 1880, showing the gash in the Sphinx's left forehead and the stump of the left lappet of the headdress. (*Collection of Robert Temple*)

The other two popular writers who have campaigned for the idea that the Sphinx is of immense antiquity are Graham Hancock and Robert Bauval, authors jointly and separately of various books on the subject. I know Graham slightly, and Robert rather well, although we have lost touch these days. We all mutually accept the fact that we are in disagreement about the extreme antiquity of the Sphinx.

In principle, it is understandable that these three authors have been driven to what I consider an extreme and untenable position with regard to the age of the Sphinx, because they take seriously the apparent signs of water erosion in the Sphinx Pit. And since Egypt is not known for heavy rainfall today, they have concluded that such water erosion must have been caused at a time when there was much heavier rainfall in Egypt than there is now. This superficially seems reasonable, although I do not believe it really is. They propose a date of about 10,000 BC for this heavy rainfall, which may or may not be justifiable. We come across conflicting claims about the climate so long ago, but I have not personally made a particular study of the ancient climate. I was never convinced by this argument from the very beginning for the simple reason that there is just no archaeological record at all for any important civilization during approximately seven thousand years of the time postulated between the "ancient rain" and the apparent beginnings of high civilization in Egypt. Whereas I am the first person to agree that there are curious anomalies about these beginnings, I cannot take seriously the suggestion that the beginnings were separated from any other signs of activity by seven thousand years of nothing. And trying to invoke the hypothesis of Atlantis seems a desperate measure, since Atlantis is a *speculation*. In other words, the logic seems weak and the evidence fragile. One idea often suggested by Robert Bauval is that the Sphinx was a lion statue that was somehow associated with the constellation of Leo rising at the spring equinox at an extremely early date. Since there is no evidence whatsoever that the constellation known to us as Leo was associated with a lion prior to the very last centuries BC in Egypt (when Babylonian influence crept in), and certainly not at some immensely remote era before that, this does not seem a feasible hypothesis. It is simply not an Egyptian tradition prior to the Ptolemaic Period.

There is plenty of evidence, as we shall see, for an alternative explanation of the signs that appear to indicate water erosion in the Sphinx Pit. And as we shall see later on, what I have to suggest is not incompatible with objections to the flowing-water erosion theories raised by Professor Lal Gauri, who

has made the most intensive geological study of the Sphinx of anyone in history, is one of the world's leading experts on limestone and its erosion processes, and strongly believes the "ancient rain" theory to be completely wrong, and I certainly agree with him.

One thing that has gone awry in the discussions of the ancient-rain theory of the Sphinx is that Egyptologists have been so horrified by this rain-erosion theory that they have attempted to counter it by denying that there are any signs of water erosion in the Sphinx Pit at all. This is a severe tactical error and merely makes members of the general public believe that the Egyptologists are being silly or stupid, or perhaps worse. The apparent evidence of water erosion is so blatantly obvious to anyone that for someone supposedly knowledgeable wholly to deny it looks disingenuous. In fact, my criticisms of "consensus reality" in the last chapter cannot apply to the signs of water erosion, for Schwaller de Lubicz has already challenged this consensus reality and pointed out that those particular new clothes of the emperor were missing. It is to the credit of West, Hancock, and Bauval that they so passionately seconded this, even if their reasoning from that point on was doubtful. But Egyptologists are making a big mistake in taking refuge in their bunkers. They should not feed the ancient-rain theory speculations by uninformed opposition or contempt alone. What we now have is a situation where neither side is right, and the arguments that have raged between them for years are all spurious and a waste of everyone's time.

So how does one resolve this situation in a reasonable way? I think the starting point is to take seriously the possibility of water erosion in the Sphinx Pit. It certainly looks as if there was a great deal of it in very ancient times. Then one has to think: How can this have been caused, if not by "ancient rain"? Certainly, as we shall see later, exposed subterranean water-erosion channels in the limestone (which is rich in such caves) were revealed by the excavation of the Sphinx Pit, and these geologically ancient channels have been further eroded since exposure. Partially this has been by natural processes that involve dew in microscopic pores, cold temperatures at night and hot ones during the day, even occasional rainstorms, and so forth. But I believe a substantial standing body of water was near at hand to increase the sources of moisture in the air, so that the processes were caused not just by dew and a rare rain shower. And furthermore, I shall describe later very specific causes for vertical scouring of the Sphinx Pit walls by water that has nothing whatsoever to do with rainfall. But first let us establish the central answer to the riddle:

I believe that the Sphinx Pit was once a moat filled with water, and that the Sphinx was an island.

The first objection that anyone might raise to this suggestion is that the Sphinx Pit is open at the east end and enclosed by cliff faces on only three sides (north, south, and west). So how could it have been a moat? However, it was on the east side that the water from the inundation of the Nile was to be found, from which the water to fill the moat must have come. We have already encountered quays in front of the Valley Temple and heard the evidence that in ancient times the water of the Nile lapped at the foot of the Sphinx Temple and the Valley Temple and may well have overflowed into them on occasion. (It was only 660 feet away, even as recently as the seventeenth century, during the inundation.) I believe it is highly possible that the floor of the Sphinx Temple was annually flooded and was intended to be, as I shall explain further a little later on. Although not visible to the naked eye today, additional ancient quays have been excavated directly in front of the Sphinx Temple. They are shown in the early aerial photograph in figure 6.8, before they were covered over again with windblown sand.

Figure 6.7. A Victorian engraving of the pyramids of Giza at the time of the inundation. (Collection of Robert Temple)

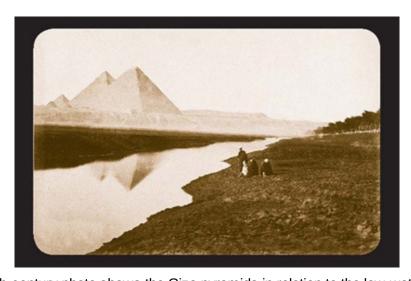

Figure 6.8. This late-nineteenth-century photo shows the Giza pyramids in relation to the low-water level of a branch of the Nile. The people are on an extended mud bank. At inundation, the water rose nearly to the level of the trees growing along the artificial bank of the Pyramid Road, which is at far right. During the Old Kingdom, the Nile was much farther toward the pyramids and rose much higher than in the nineteenth century, lapping at the door of the Sphinx Temple (not visible here, to left of photo, where the plateau slopes down). (*Collection of Robert Temple*)

Figure 6.9. This photo is from a glass lantern slide taken circa 1900 or earlier from the Giza Plateau at the foot of the Great Pyramid, looking back toward distant Cairo. Victorian visitors are arriving as tourists. In the background is the long road leading

into Cairo, which runs across a completely empty floodplain. In those days, before the construction of the Aswan Dam, the annual inundation of the Nile spread across this plain and lapped at the foot of the Giza Plateau. In the long, thin strip on the horizon, Cairo is faintly seen. Today, the floodplain has dried out completely and has been built upon. Cairo now extends from the distant horizon seen here all the way to the pyramids, and the main Pyramids Road, built on top of the trackway seen here, is now an artery of crazy traffic surrounded by modern buildings inhabited by millions of people. The population of Cairo, which at the time of this photo did not exceed six million, is now unquantifiable; estimates vary between fifteen and thirty million, depending on how many drifters, vagabonds, and homeless one counts, whether the estimated two million squatters in the City of the Dead are included, and so forth. The only thing that is certain about modern Cairo is that there are too many people, and since Egyptians believe it is a good thing to have as many children as possible, the population is exploding. (*Collection of Robert Temple*)

Figure 6.10. This is how the Giza Plateau appeared toward the end of the nineteenth century as seen from the tree-lined road leading from Cairo to the pyramids (on right). The Nile is low at this point, as it is not inundation time. (*Collection of Robert Temple*)

Figure 6.11. This French photo from the late nineteenth century shows the pyramids on the Giza Plateau in the background, from the banks of a part of the Nile when it is at a low level. It resembles figure 6.10; the road leading to the pyramids from Cairo is out of sight to the right, where the land to the left is the floodplain seen in figure 6.9, which would be covered by water during the annual inundation. (Collection of Robert Temple)

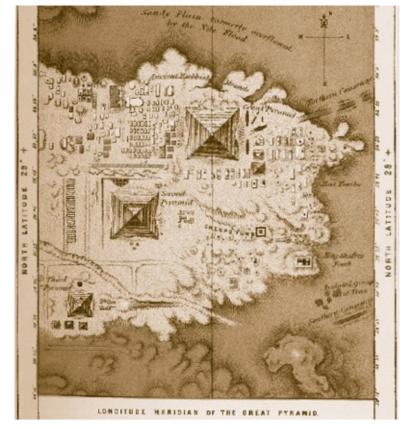

Figure 6.12. Charles Piazzi-Smyth's plan of the Giza (he spells it "Jeezah") Plateau, the pyramids, and the Sphinx, reproduced from his book Our Inheritance in the Great Pyramid, London, 1874 (folding plate III). Piazzi-Smyth's main purpose was to discuss the geodetic siting of the Great Pyramid and its longitudinal north-south meridian line, which bisects it, as shown here. However, for our purposes in connection with the Sphinx, this plan's usefulness is for showing in graphic color the Old Kingdom Nile floodplain (represented as brown). It shows that the Sphinx lies near the edge of this floodplain, at the right of the tan area. The word "Sphinx" is written in front of it, on top of the mound that concealed the still undiscovered Sphinx Temple. The structure we now call the Valley Temple is labeled here "King Shafre's [Khafre's] Tomb." The "Southern Causeway" is the top of a massive megalithic wall known today as the Wall of the Crow, which may well have had the double function at that time of acting as a causeway during the inundation period. The Chephren Causeway was still unknown at this time and is not depicted. The square called "Cheops Tomb" is what is today called Campbell's Tomb, and we have no idea who was buried in it; it is slightly north of the Chephren Causeway and is not open to the public, having a deep and dangerous open shaft. The "Northern Causeway" is the Cheops Causeway, now obliterated by housing. At this time, an extension of it into the floodplain area was still used, as it had been for millennia, as a genuine transport causeway across the flooded plain. Its use for that purpose is described in many of the early travelers' reports. This part of the Cheops Causeway was not only maintained by the reigning Mameluks and Turks but probably also extended by them, so no one knows where the authentic Cheops Causeway really ended and where its more recent extension, dating perhaps from the Middle Ages, commenced. In any case, none of it past the plateau's edge can be traced today, so we will never know. Because Piazzi-Smyth was an astronomer, his cardinal points as indicated on this plan are to true north and south rather than magnetic compass directions, in contrast to so many plans by archaeologists who do not even know the difference between geographical north and magnetic north. (Collection of Robert Temple)

Figure 6.13. This old photo, probably dating from between 1860 and 1890, has a handwritten inscription on the back: "View of the

Pyramids after the Nile has receded." The view is an unusual one, taken from the southwest, with the Pyramid of Mycerinus and its three tiny satellite pyramids in the foreground and the Pyramid of Chephren in the background on the left. (The Great Pyramid is obscured and cannot be seen behind the Pyramid of Chephren from this angle.) The reference to the receding of the Nile is, of course, to its receding after the annual inundation (which no longer happens because of the Aswan Dam). The photographer's comment seems to imply that during the nineteenth century, the Nile at the inundation sometimes extended up to this southwest corner of the Giza pyramid field. I have come across other evidence that suggests that the inundation water did indeed swirl around to this location. In fact, the satellite photo seen in figure 6.22 shows walls and structures near the Pyramid of Mycerinus that I think may have been connected with a facility for unloading stones and building materials from barges. I believe this was the "tradesmen's entrance" to the Giza Plateau. (Collection of Robert Temple)

Figure 6.14. A view from the Sphinx Temple looking westward along the south side of the Sphinx's body with the Chephren Causeway on the left and the Pyramid of Chephren in the distance. The edge of the Sphinx Pit shows evidence of a continuous horizontal watermark from when it was filled with water as the Sphinx Moat, and that was the level of the water surface. As for the body of the Sphinx, on the right, this angle of light enables us to see clearly the smearing of the body with modern cement, like icing spread on a cake. The top portions of the Sphinx body visible here are the actual carved rock (in a highly eroded state), whereas the lower portions are reconstituted of repair blocks, and the smeared cement has been used to fill in the holes in both. (*Photo by Robert Temple*)

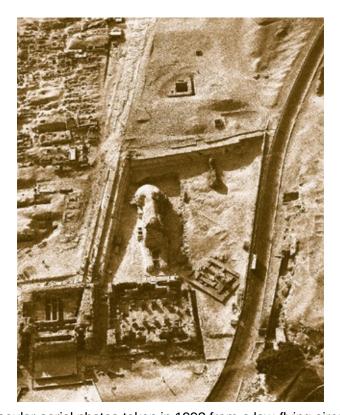

Figure 6.15. This is one of the spectacular aerial photos taken in 1992 from a low-flying aircraft by Marilyn Bridges and published in her large-format book *Egypt: Antiquities from Above* (Bulfinch Press, New York and London, 1996). This photo reveals many crucial features of the Sphinx and its surroundings, which are not so easily visible in any other view. The prominent road on the right is the modern access road to the pyramids for tourist buses that enter the Giza Plateau from the village to the east of the Sphinx, known in Arabic as Nazlet el-Samman but called Busiris in ancient Greek and Djedu in ancient Egyptian. The Sphinx Temple is visible at the foot of the Sphinx; as discussed previously, it was covered in sand and completely forgotten from circa 2000 BC until the 1930s. The temple to the left of it is called the Valley Temple and is connected by the Chephren Causeway to the Pyramid of Chephren, higher up the hill. The Valley Temple is partially open to tourists, whereas the Sphinx Temple is not. The

little square temple to the right of the Sphinx, built at an angle, is a small and not very interesting New Kingdom edifice honoring the Sphinx. It was built in ignorance of the existence of the Sphinx Temple, which was covered in sand by then. The square black hole in the sandy area behind the Sphinx is the shaft grave known as Campbell's Tomb.

I would like to call attention to the tiny size of the Sphinx's head (seen also clearly in the horizontal wide-angle photo I took for figure 3.15). Also visible in this view is the tapered waist of the original carved figure, which is typical of a dog but not of a lion. The paws of the Sphinx, front and back, are essentially artificial, having been heavily reconstructed in Greek and Roman times and further reconstructed in modern times, so their leonine appearance is not authentic or original. The nature of the Sphinx Pit, in Old Kingdom times the Sphinx Moat, is dramatically obvious here. The wall of the Sphinx Temple on the side facing the Sphinx (the temple's western wall) was the barrier to the water in the moat. The water was led into the moat through the channel between the two temples, here seen in deep shadow, and the sluices to retain the water were at its western end (see my photos of the traces of those sluices in figures 6.31 to 6.42). The water of the Nile at the period of the annual inundation during the Old Kingdom (the Pyramid Age) lapped at the feet of the two temples, where there were quays, which have been partially excavated. Raising the water from that level to the level of the slightly higher Sphinx Moat was not a problem (see figures 6.23 to 6.27). The Sphinx Moat in the Old Kingdom was the sacred lake known in the Pyramid Texts as Jackal Lake, because the crouching Anubis sat in the middle of it. It also had other names and honorific titles such as Lake of Fire, Canal of the God, Canal of Anubis, Winding Waterway, Lake of Cool Water, and Lake of Life. The four sacred jars containing the internal organs of each deceased pharaoh in Old Kingdom times were ceremonially washed in the waters of Jackal Lake after his death, before they and his mummy were placed in his tomb. Every year, possibly in connection with the annual Festival of Sokar (see figure 7.22), the pharaoh made a ceremonial journey around the statue of Anubis in a little boat; the remnants of a tiny landing stage for this ceremony appear to survive in the center of the west wall of the Sphinx Temple. Another place of descent into the Sphinx Moat seems to have been at the northeast corner of the Valley Temple (see figures 6.41 and 6.42). The dredging of the Sphinx Moat, which would have been a drastic necessity several times a year because of the problem of the windblown sand, must have taken place at several points, one of which is the vertical crevice in the bedrock on the left side of the Sphinx Pit in this photo, in the center (shown also in figure 6.57, where Olivia is seen climbing up it). The vertical fissures in the bedrock due to water erosion, mistakenly imagined by some modern writers as being due to impossibly prehistoric ancient rain, were caused by the repeated dredging over several centuries, which resulted in vast torrents of water pouring back down into the moat after each dredging effort. The greatest amount of sand would have accumulated at the west end of the Sphinx Moat (supported by modern archaeological evidence discussed), and the shelf left in the Sphinx Pit there seems to have served as the primary service access for the maintenance of the moat. The ancient name for the immediate area around the Sphinx, and in particular for the Valley Temple, was Rostau (or Rosetau). There are reasons to believe that the Valley Temple was originally a Temple of Sokar (later called a Temple of Osiris, by the time Osiris had largely replaced Sokar in religious mythology), the original lord of the underworld, but that Pharaoh Chephren, who may have had ego problems, turned it into a shrine for himself and filled it full of his own statues. We are deeply indebted to Marilyn Bridges for the immense trouble she went to in her struggles to get permission to take her invaluable aerial photos of ancient Egyptian monuments. (Photo copyright © 1992 by Marilyn Bridges)

Mark Lehner describes these quays that cannot at present be seen:

A quay or revetment in front of the Sphinx Temple was revealed by drillings, as much as 16 m (52 ft) deep. It probably continues south in front of the valley temple, from which point ramps lead to the two doors of the temple. . . . In 1995 Zahi Hawass recleared the area, revealing that the ramps cross over tunnels framed within mudbrick walls that formed a narrow corridor or canal running north—south. In front of the Sphinx Temple the canal runs into a drain leading northeast, probably to the quay buried below the modern tourist plaza. <sup>6</sup>

We must keep in mind also that the means of keeping water trapped in the Sphinx Moat on the east side was by means of the west wall of the Sphinx Temple. This rose up very high (see figures 6.16 to 6.18, 6.20, 6.50, and 6.56). Let us stop for a moment and think of just how bizarre it was for there to be this temple wall immediately in front of the Sphinx's face. There is no passage or doorway leading to the Sphinx from the Sphinx Temple. The Sphinx Temple sits directly in front of the Sphinx, and yet *you could* not get to the Sphinx from the Sphinx Temple!

If you think the Sphinx Temple was built for the purpose of worshipping the Sphinx, then you have to explain why there was no connecting passage or doorway between the two. The Sphinx was boxed in and blocked off and could not be approached from the building in front of it. Why would anybody do this?

Apart from that, the Sphinx Temple blocked the view of the Sphinx so that no one could see the Sphinx properly from the front. Imagine someone building a wall in front of the "Mona Lisa" in the Louvre, so that visitors to the museum could see the painting only if they brought along a portable ladder to stand on.

Since we are faced with the indubitable fact that this monstrous obstruction exists directly in front of the Sphinx, the only logical explanation is that this was done on purpose for a very good reason. I suggest that the Sphinx Temple's west wall was the fourth wall of the Sphinx Moat. I am convinced that the Sphinx Temple's purpose of obstructing the view was really to obstruct the outflow of the water in the moat, which had been brought in from the Nile at the time of the river's rise at the annual inundation.

In 1739, Richard Pococke visited Giza and stated that at the inundation, the Nile rose to a point in that year that was only 660 feet from the Sphinx itself. That is a distance of 220 yards (201 meters), which is only half the extent of a single circuit of an American high school track, the conventional circuit of which is a quarter of a mile, or 440 yards. It is only 10 percent more than twice the length of the 100-yard dash in American track events, which can be run in approximately ten or eleven seconds by a sprinter. Consequently, if we ignore the sandy surface and assume a firm surface, a sprinter in 1739 could have run from the Sphinx to the Nile in about 25 seconds at the time of the annual inundation. And that was after the Nile had moved considerably to the east, whereas it is known to have been much closer to the Sphinx in Old Kingdom times, and as previously mentioned, the level was 26 feet higher during the Middle Kingdom than it was in the eighteenth and nineteenth centuries.

Figure 6.16. Looking up at the face of the Sphinx from the floor of the Sphinx Temple at its western end. The walls here are carved out of the solid bedrock, with limestone blocks added above. This western wall would have acted as a massive barrier to the outflow of any water from the Sphinx Moat during the Old Kingdom. (*Photo by Robert Temple*)

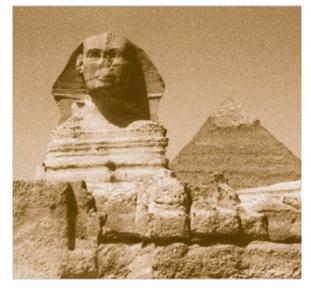

Figure 6.17. The Sphinx seen head-on from inside the Sphinx Temple. What remains of the massive limestone west wall of the temple rises well above what would have been the water level of the Sphinx Moat when it was still in use. On the far side of the wall, just in front of the Sphinx (but today obscured by a spotlight installation), there are slight remains of a limestone platform where the pharaoh probably once stood alone for a ceremony, having disembarked from a small boat, as there were steps leading down on either side of this platform. (*Photo by Robert Temple*)

Figure 6.18. This view inside the Sphinx Temple shows the truly extraordinary erosion patterns visible on some of the stones. One has to remember that from about 2000 BC, this temple was entirely covered by sand, until it was rediscovered and excavated in 1936. All this erosion therefore had to take place before 2000 BC. If you go past the eroded stone at left and turn left, you are standing inside the northwest "magazine," which is a word used by archaeologists to refer to a storage space or room, seen in figure 6.19. I believe that with the inundation of the Nile during the Old Kingdom, the entire interior of the Sphinx Temple may well have been flooded for at least three months of the year. The two western magazines, which I believe held boats, would have had considerable water standing in them during that part of the year. (*Photo by Robert Temple*)

Figure 6.19. The Sphinx Temple has various strange design features. At the western end, there is a pair of these seemingly inexplicable chambers of a kind that tend to be called "magazines," that is, they are assumed to have been storage rooms of some kind. This is the magazine in the northwest corner of the temple. The western wall of the temple is on the right. A twin of this chamber is in the southwest corner of the temple. Anyone's guess is as good as another's, but my guess about these two chambers is that they were used for the storage of boats, which were lifted out, passed over the wall to the right, and set down in the water of the Sphinx Moat for special ceremonies. The floor design suggests something of this sort, since it seems obvious that something was stored here that was long and narrow and had its bottom along the center, and the stone walkway surrounding the chamber on three sides suggests a means of access by foot to the sides and far end of something long and narrow. What could that be besides a boat? For those who refuse to accept the idea of a Sphinx Moat, the chambers could still have contained long boats nevertheless, since we know that sacred barques were carried in procession at Giza during the Festival of Sokar. I therefore suggest that the northwest and southwest magazines were storage chambers for long ceremonial boats, whether sacred barques that never touched water or real boats to be lifted over the wall and placed into the moat. (*Photo by Robert Temple*)

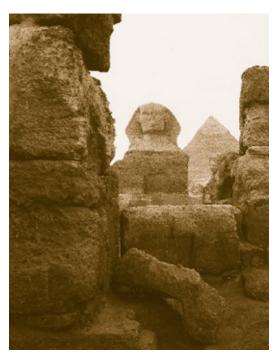

Figure 6.20. The Sphinx seen from within the Sphinx Temple at its eastern end. (*Photo by Robert Temple*)

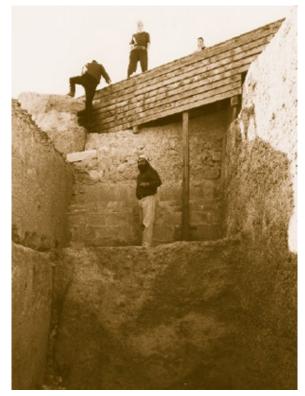

Figure 6.21. This is the western end of the North Trench, which lies along the northern wall of the Sphinx Temple and is padlocked with an iron gate at the eastern end to keep tourists out. At the western end, the bottom half terminates in solid bedrock, as seen here with a man standing on it. The wall to the right is also solid bedrock, being the cliff face of the plateau. Olivia stands looking down at me from the top, in the center. The woman whose head is showing at the top right of the photo is the Egyptian antiquities inspector. The two men in the photo are Greek friends. That this passage ends in a bedrock barrier shows that it could not have served as a water channel in the same way as the channel between the two temples at the southern wall of this temple. This passage was made necessary by the construction of the Sphinx Temple, since otherwise its northern wall would have been laid flat up against a cliff. Some of the limestone blocks in the northern wall are gigantic and must weigh in excess of forty tons. The wooden walkway at the top is part of the modern access to the Sphinx Pit. The small New Kingdom temple of Amenhotep II (see figures 7.3 to 7.5) stands nearby, and the stones lying on top of the bedrock in the center may have been part of its New Kingdom foundations, though I do not believe the details of the stones and rubble at this point have been studied or recorded; and as they are now entirely covered by the wooden access ramp, I could not study them properly. But I suspect the disorderly stones and rubble that constitute the top level must have been added at the time the modern ramp was constructed. (*Photo by Robert Temple*)

Since a massive amount of water was ready at hand for filling the Sphinx Moat in Old Kingdom times, a point agreed on by all Egyptologists today, why not take the further step of assuming that it was actually done (see figure 6.18)? To raise the water that small amount was a relatively simple task with even the most primitive water-raising devices, such as the swape, or well-sweep, technically known as the counterbalanced bailing bucket, which is known to have been used in Old Kingdom Egypt. (Its name in Arabic is  $sh\bar{a}d\bar{u}f$ . See figure 6.26.) For such a large volume of water, several of these of considerable size would probably have been used, and for weeks on end. But this posed no engineering difficulty even for a primitive people and certainly none to a people capable of building the pyramids! All that was needed for this task were time and plenty of laborers. Swapes were often used in large numbers simultaneously in Egypt:

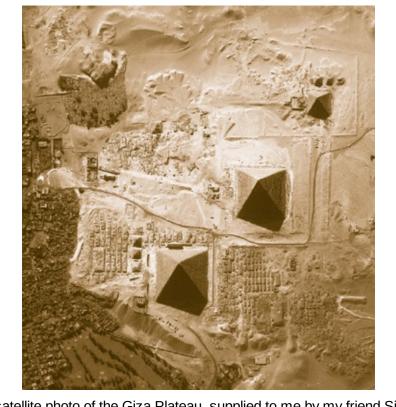

Figure 6.22. This is a NASA satellite photo of the Giza Plateau, supplied to me by my friend Simon Cox, to whom I am very grateful. Many strange features and buried structures invisible on the ground to the naked eye can be seen through the sand in this photo, particularly unexcavated walls around the precincts of the Pyramid of Mycerinus (top). Also, this photo shows that the row of tomb chambers behind (to the west of ) the Pyramid of Chephren are not oriented north-south, as they seem to be when viewed casually at ground level. The Causeway of Mycerinus may be seen shooting off to the left and being lost in the sand. The Chephren Causeway, emanating from the Pyramid of Chephren in the center of the photo, shoots off to the left and ends at the Valley Temple, passing the Sphinx, which is below it in the photo. (The temple directly in front of the Sphinx is the Sphinx Temple.) The Great Pyramid is at the bottom, and in this view from above we can see that the west face (at right) has a line running down the middle, which is known as its apothegm, a slight indentation invisible from ground level; we can see also the track of the now demolished Cheops Causeway shooting downward and to the left, terminating at the cliff edge, although it once continued farther in the floodplain below, but is now built over. The town at the left in the photo is the vast, sprawling, and growing Nazlet el-Samman, which clearly wishes to gobble up Giza. In Greek and Roman times it was called Busiris, by the Napoleonic Expedition it was called Bousyr, in ancient Egyptian times it was called Djedu. The steepness of the escarpment rising from the floodplain to the plateau is best seen below the Great Pyramid, where the slope is a sharp one. The rectangular nodule beside the Great Pyramid, above it in the photo, is the modern structure built to house the ancient boat that was excavated from a boat pit and is now a museum. The three squares to the left of the Great Pyramid are known as the Queen's Pyramids. The snaking form threading through the middle of the photo is the modern road; it ends in an oval open area at the extreme left. If you look closely at the bottom (northern) edge of the Chephren Causeway in this photo, about halfway between the Sphinx and the pyramid you will see a crescent-shaped hole just peeking out and extending beneath it: that is the entrance to the so-called Osiris Shaft at Giza. To the left is a square black hole: that is the shaft leading to what is called "Campbell's Tomb." Neither of these subterranean features is accessible to the public, or indeed to most archaeologists either. If you look at the area containing trees in the top lefthand corner, that is the modern Arab cemetery. Just to the left of it you can see a long wall shooting out to the left, which is called "The Wall of the Crow," which functioned as a causeway during the times of inundation. Above it in the sand is the area of the ancient workers' village. This photo shows how the inundation waters once swirled round from just in front of the Sphinx Temple in an arc to the area southward and eastward (south is top, just above the Pyramid of Mycerinus). Even until the twentieth century, floodwaters sometimes reached this far. The buried structures above and to the left of the Pyramid of Mycerinus may perhaps be the remains of a landing stage for barges during the inundation, for the transport of materials. The strange round shape at far right center is a stage where operas and events are staged for the public. (Photo courtesy of National Aeronautics and Space Agency,

Batteries of swapes raising water in successive levels are often seen in Babylonian and ancient Egyptian representations, described in Arabic MSS. [etc.] . . . A later development was to elongate the bucket's spout into a flume . . . this being linked parallel with a counterweighted beam above, and so arranged that it automatically empties itself into the receiving channel on an upward motion. . . . This was really a combination of the ancient swape with another device, the *mote*, consisting only of

USA)

a scoop-shaped piece of wood suspended at its centre from a kind of a light derrick and used simply to scoop up the water. . . . In India the operation of the device is assisted by a moving counterpoise, i.e. by men who walk back and forth along the upper beam. . . . This is true also of the large  $sh\bar{a}d\bar{u}fs$  both in Egypt and in India. The  $sh\bar{a}d\bar{u}f$  will service a lift of from 4 to 10 feet [i.e., raise the water that high], and while the flume-beamed swape will not lift more than about 3 feet it will carry much larger amounts of water at each stroke. 9

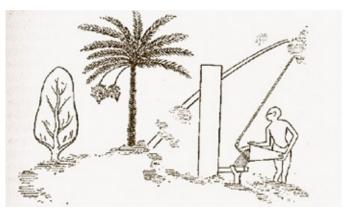

Figure 6.23. A simple water-raising device in use in ancient Egypt in an engraving of an ancient drawing from Adolf Erman, *Die Welt am Nil (The World on the Nile)*, Leipzig, 1936, figure 2, in the section "Land and People." The caption merely says "Bucket in ancient times." This is apparently of New Kingdom date.

Figure 6.24. It took only two men and a bucket to move a significant amount of water at a single site in traditional Egypt. All they had to do was keep going. (*Collection of Robert Temple*)

Batteries of swapes would have been quite sufficient to raise the water the small distance to fill the Sphinx Moat (see figures 6.26 and 6.27). The water-raising machinery may have been more advanced than swapes, but the study of ancient Egyptian engineering, as far as I am aware, is too undeveloped for me to discover whether in Old Kingdom times the more efficient machines known as norias (see figure 6.25) or those known as pot chain-pumps ( $s\bar{a}q\bar{i}yas$ ) or "camelwheels" ( $daul\bar{a}bs$ ), later ubiquitous in Egypt, may have been known and used. Whether the water-raising was accomplished in the slower and more elementary manner with swapes does not really matter, since there was no shortage of labor to accomplish this tedious process, and in engineering terms it was simply a brute-force method applied to an incredibly simple requirement, which the most primitive people could have managed easily. Raising

water to fill the Sphinx Moat was, compared to building even a small pyramid or excavating a deep shaft, mere child's play.

We have other evidence that this sort of thing was routine in ancient Egypt. The Greek geographer Strabo (64 BC–AD 25) recorded in his *Geography* that a Roman encampment near the site of what is today Cairo received its water supply from the Nile by a system of wheels and screws operated by 150 men, which raised the water and transported it along a ridge. <sup>11</sup> The passage reads:

Figure 6.25. This is a noria water wheel, used for lifting quantities of water out of the Nile for irrigation purposes up until modern times. Although the noria did not yet exist in Old Kingdom times, as far as we know, it represents a successor to the *shadouf* system, which did exist then (see figures 6.26 and 6.27). At all times throughout history, the Egyptians have employed massive numbers of water-raising machines and shifted huge quantities of water. They were hydraulic engineers on a grand scale. (*Collection of Robert Temple*)

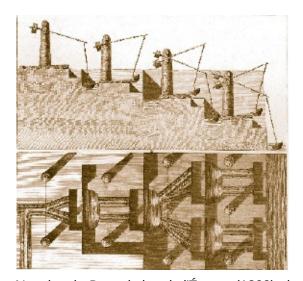

Figure 6.26. These engravings from the Napoleonic *Description de l'Égypte* (1809) show the details of the traditional Egyptian water-raising system known as *shadouf* in Arabic. With such a simple system, the entire Sphinx Moat could easily have been filled by Nile water, since manpower was essentially unlimited, and these devices could have been worked around the clock. The traces of sluices to control the water when it rose to the correct level are seen in figures 6.31 to 6.42, which I took just days before the evidence was covered over by modern "restoration" work on the northern foundations and base of the Valley Temple at Giza. (*Collection of Robert Temple*)

Figure 6.27. A view of a traditional *shadouf* water-raising system in operation circa 1798–1801, as portrayed in the Napoleonic *Description de l'Égypte*. This shows how only a dozen men at a time are needed to raise enough water from the Nile level of Old Kingdom times to the level of the Sphinx Moat. (*Collection of Robert Temple*)

In sailing up the river [the Nile] we meet with Babylon, a strong fortress, built by some Babylonians who had taken refuge there, and had obtained a permission from the kings to establish a settlement in that place. [This is incorrect, but was believed at that time. The name Babylon in Egypt has a different origin, and a tower of this "Fortress of Babylon," or at least a more modern tower on the site of an even older one, now serves as the entrance to the Coptic Museum in Old Cairo.] At present it is an encampment for one of the three [Roman] legions which garrison Egypt. There is a mountainous ridge, which extends from the encampment as far as the Nile. At this ridge are wheels and screws, by which water is raised from the river, and one hundred and fifty prisoners are [thus] employed. The pyramids on the other side [of the Nile] at Memphis may be clearly discerned from this place, for they are not far off. 12

For holding the water within the Sphinx Moat, all that was necessary was the western stone wall of the Sphinx Temple and a strong sluice gate in the passage between the Sphinx and Valley Temples. The water must have been led into the Sphinx Moat along this passage that separates the Valley Temple from the Sphinx Temple (see figures 6.28 to 6.30), and that connects the area to the east of the temples, where the Nile water was, and the Sphinx Moat directly. As we shall see in a moment, I have discovered and photographed evidence there of ancient sluice gates.

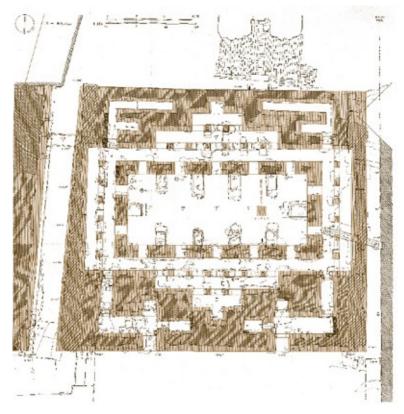

Figure 6.28. This is probably the most accurate ground plan of the Sphinx Temple ever published. This remarkable labor of love was accomplished by the German archaeologist Herbert Ricke, based on his excavations and surveys. He did not use the usual term Sphinx Temple for the building but called it the Harmachis Temple, after the god Harmachis (a late name for the statue of the Sphinx after it was deified). However, it is too confusing to have two names for the same temple, so we use the more usual name of Sphinx Temple, which all the English-speaking archaeologists use. This is the temple, closed to the public, that sits directly in front of the Sphinx, whose front paws and the pavement in front of them can be seen at the top of this drawing. Near the center of the (west) wall at the top of this temple plan, directly in front of the Sphinx and opposite the space between its paws, are two steps. I believe these to be the remnants of the place of descent of the pharaoh into his boat to sail around Sphinx Island, as described in the main text. It was probably also the place where the four jars containing the pharaoh's internal organs were ceremonially washed in the lake after his death, also as described in the main text. The main advantage of this plan for us, however, is the clear depiction it gives of the passageway between the two temples (shown here as a white corridor between the two dark buildings, at the left of the plan). This is the passage through which the flow of Nile water was regulated by means of sluices (traces of which are seen in figures 6.33 to 6.38) into and out of the Sphinx Moat. At the top left of the plan, the Chephren Causeway commences and abuts the northwest corner of the Valley Temple (the dark structure whose northern wall is shown at the far left of the plan). The photos in figures 6.37, 6.39, and 6.40 show the swirling water patterns in the stone at this point, caused by the rushing water when the sluices were opened and closed, and figure 6.42 shows the remains of the stone stairs descending at this point into the sluiceway for purposes of maintenance and operation of the sluices. This passageway has now been so thoroughly restored with new stone blocks (see figures 6.31 and 6.32 for this work in progress) that all traces of its original surface, together with evidence of the sluices, have been obliterated, so my photos are the only record that remains of the true purpose of this passage and the means by which the ingress and egress of water were controlled and regulated. The North Trench shown to the right of the Sphinx Temple, which I have carefully explored (literally after jumping about 30 feet down into it), never went through to the Sphinx Moat, and the original rock of the plateau blocks it completely at its western end, though that is not particularly clear here. The North Trench therefore had nothing to do with regulating the water flow but was required to give space for the workers to construct the temple, as the north wall of this passage is a solid rock cliff, shown here in dark shading. (The illustration is Plan 1, the folding plan at the back, of Herbert Ricke, Der Harmachistempel des Chefren in Giseh (The Harmachis Temple of Chephren at Giza), in the series Beiträge zur Ägyptischen Bauforschung und Altertumskunde, Vol. 10; see notes to main text.)

Figure 6.29. Looking from the water channel between the temples toward the modern gate across the entrance into the Sphinx Moat. On the right is the southeast corner of the Sphinx Temple. (*Photo by Robert Temple*)

Figure 6.30. This view from the top of the north wall of the Valley Temple shows clearly how the Sphinx Moat ran directly out and into the northwestern corner of the Valley Temple, circumventing the Sphinx Temple, which acted as the moat's eastern barrier. Indeed, from this viewpoint we can appreciate how the strange angle of the southern wall of the Sphinx Moat had a clear purpose, which was precisely to lead the water around the Sphinx Temple and into the narrow channel where the sluice gate was, which regulated the level. The remains of the Sphinx Temple are on the bottom right of this photo. The barred metal barrier closes off this narrow access today so that people who are admitted into the Sphinx Pit cannot wander down between the two temples. (Photo by Robert Temple)

Figure 6.34 is a photo I took (as a result of my special access to the site) of the northwest corner of the Valley Temple, showing what appear to be long lines of water erosion along the base, following the entire line of the passage that would have led to the Nile in ancient times. I photographed all this evidence at the very last minute in 2001. The scaffolding was for the restoration of the wall, already well under way at the time, whereby new stone was laid over the original surface, wholly effaced all these ancient indications of water erosion and destroyed all such evidence forever. No one can ever take my photos again! (See figures 6.31 and 6.32.) Unexplained holes as well as larger indentations are seen in the original stones, which indicate that in some previous era wooden, brick, metal, or detachable stone fixtures were inserted into them. Figures 6.33 to 6.38 show evidence of carved indentations and depressions in the stone of the north wall of the Valley Temple that appear to be slots for sluice-gate mechanisms. There are also bolt holes drilled into the wall, apparently for fastening the sluices with metal bolts.

Figure 6.31. The north wall of the Valley Temple undergoing restoration. Modern pieces of limestone have been cut and inserted into holes; cement has been smeared all along depressions to even them out. All traces of anomalies are being erased. This is despite the fact that tourists never come here and never will. The horizontal lines showing ancient water erosion run along the lower wall at a level above the base blocks. (*Photo by Robert Temple*)

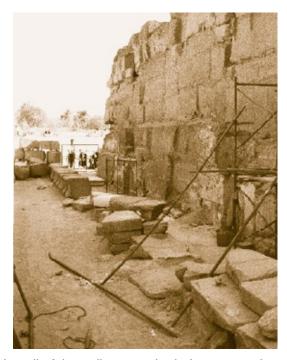

Figure 6.32. The eastern end of the north wall of the Valley Temple during restoration. We see piles of modern blocks of stone lined up to be placed and cemented against the base of the temple wall, which will forever obscure its true features and render impossible any closer reconstruction of what was going on here in the Old Kingdom. The Sphinx Temple is to the left of this photo and cannot be seen here. (*Photo by Robert Temple*)

Figure 6.33. This photo is taken looking due west, from the floor of the water channel between the two temples. To the upper right is the iron gate sealing off access to the Sphinx Moat. The limestone directly ahead at the end is natural limestone bedrock. The

stone on the left is the north wall of the Valley Temple. Immediately to the left are two ancient bolt holes. The long, dark, vertical pole is part of some modern iron scaffolding erected for the process of "restoring" this wall—in other words, destroying all the ancient evidence in the interests of tidying up, filling in, and smoothing out, which is precisely the mentality that turned the Sphinx into something worse than a Botoxed movie star, resembling Lenin's corpse more than an ancient monument. The horizontal erosion lines on the Valley Temple's wall show clearly that the water level was kept constant during the inundation period up to the level of the Sphinx Moat's bedrock floor. These standing-water lines indicate very clearly that the channel was never dry during that portion of the year. The thin path of stones laid along the channel and leading toward the ancient stairs is a modern pathway for workers. The lumpy stone at lower right is the remains of a platform, with indentations for sluices and mechanisms at its base. Only the single stone seen protruding at the center right is part of the south wall of the Sphinx Temple. (*Photo by Robert Temple*)

Figure 6.34. In the foreground, the steps descend into the passage between the Sphinx and Valley Temples, with the Valley Temple's north wall on the right. Just beyond the steps are the two indentations carved out of the rock that appear to be connected with the use of a bolt. Beyond them is the long vertical slot carved out of the rock, possibly in connection with a thick sluice gate. The protruding limestone blocks along the bottom of the passage on the right exist only here, from the steps to the other side of the apparent sluice-gate depression. They may thus have been required only in association with a sluice gate at this point. The scaffolding at left was being used at the time these photos were taken to restore this wall, thereby obscuring its ancient features forever. I believe the long horizontal striations along the base of this wall are from water erosion. The water was generally kept standing at that level during inundation time, and the thick sluice gate would have commenced only above that level (at the base of the carved depression) to regulate and retard inflow and outflow higher than this level to keep the moat level stable. There would have been a great deal of water pressure against this sluice gate, which effectively held back the entire Sphinx Moat contents. This would explain its extraordinary thickness. It is possible that the carved depression may have been for a sliding stone counterweight. It is a tragedy that the clumsy restoration of this wall has obliterated so much evidence that might have been examined more closely. (*Photo by Robert Temple*)

Figure 6.35. The northwest corner of the base of the Valley Temple. The cubicle at the far corner of the base of the temple is at extreme right. Steps lead down into the passage running between the Sphinx and Valley Temples. We see clear traces here of indentations and depressions cut into the base of the Valley Temple, which seem to be evidence of a sluice at this point to control the inward and outward flow of Sphinx Moat water. Just above the bottom step is what appears to be the receptacle hole for a bolt

carved out of the rock. A carved slot for what may have been part of a thick sluice gate is in the upper central portion of the photo. (*Photo by Robert Temple*)

Figure 6.36. This photo shows particularly well the indentations cut into the left side of the base of the eroded stone platform at the right of the photo and, at the left, the Valley Temple's north wall for the various sluice mechanisms, counterweights, bolts, and barriers to control the water flow into and out of the Sphinx Moat during the inundation period. The south wall of the Sphinx Temple is out of view to the right. The cubicle cut out of the bedrock is out of view to the left at the end of the Valley Temple's wall; it may be seen in figures 6.37, 6.41, and 6.42. The horizontal water erosion marks in the lower portion of the wall of the Valley Temple are here very clear, resembling those that continue along the bottom of the Sphinx Moat beyond. It should be remembered that the Valley Temple wall is made of limestone blocks, which is why its watermarks are perfectly horizontal, whereas the wall of the Sphinx Moat is solid bedrock, which is why its eroded strata follow the softer layers of limestone in the bedrock and are not precisely horizontal, although the causes for the two sets of watermarks are the same, namely standing water over periods of centuries. (*Photo by Robert Temple*)

Figure 6.37. Detail of the base of the Valley Temple wall at the northwestern corner. On the extreme right is the base of the cubicle and at bottom left are the steps. The possible bolt holes are in the center of the photo, and the possible sluice-gate depression is beyond. The strange protrusion of limestone blocks at the base of the wall is seen here from above, already smeared over on top by modern cement. (*Photo by Robert Temple*)

Figure 6.38. A closer view of the apparent bolt slot and sluice-gate slot in the base of the northwestern corner of the Valley Temple. Modern cement is smeared into the base wall here, running from the top of the second step along the photo, as part of a clumsy restoration of the structure. (*Photo by Robert Temple*)

The water-erosion features of this wall are now a thing of the past, and I believe that my photos of them may be the only ones in existence, due to the fact that this area has been sealed off from visitors for the best part of living memory. Certainly the interpretation that I would give to my set of photos is that they suggest that a body of standing water sat in the channel for centuries, sometimes higher and sometimes lower, and as it led toward the Sphinx Moat, it was the channel by which the water in that moat was regulated during the Old Kingdom. We have to remember that these features were buried under sand during the New Kingdom and were only cleared in 1936 for the first time in approximately four thousand years. Therefore, all these strange carved and drilled features in the stone must date from some time prior to 2000 BC.

The water erosion certainly has not occurred since 1936, so it must therefore have occurred in the Old Kingdom, during the period circa 2500–2200 BC. This photographic and physical evidence should therefore be accepted until such time as anyone can produce any alternative explanation for it. Personally, I have to admit that my powers of imagination cannot summon up any alternative but to accept that Nile water stood here, was let in and out here, and from here was carried through to the Sphinx Moat. Some of the curious niches, indentations, and holes in the rock and stone seen at this location may have been connected with the operation of the water-raising equipment, counterweights for raising and lowering devices, sluice gates, and other details of the managing of the water. Certainly there must have been some purpose associated with these many anomalies, some of which were definitely carved out of the stone and rock with great care in Old Kingdom times. Alas, most of these also must have been covered up now by the restoration stones, and not only are my photos probably the only record of them, but I was not in time to photograph them all, as the restoration was well under way. There is no record at all of the others that must have existed. Even before the restoration stones were applied, modern stone had earlier been inserted into some gaps and cement had been pushed into holes to render them level and smooth, as my photos also show. There is thus no photographic record of the pristine evidence in its entirety.

At the very point where the channel between the two temples spills directly into the Sphinx Moat, a clear swirling pattern in the rock is visible, as recorded in my photos in figures 6.37, 6.39, and 6.40, which seems to indicate repeated rushing of water from the channel into the moat when a sluice was raised. The water must therefore have been raised into the narrow channel, and when it had reached a certain level, a sluice was lifted so that the water thus raised could pour into the moat. A full engineering

study of all these possibilities should be undertaken by hydraulic engineers. To study the subject properly, they should build a scale model of the moat and inlet, calculate the variations of the hydraulic pressures and flows due to the reduction in scale (of the model), and then calculate and plot the hydraulic phenomena. This should then be illustrated by computer graphics showing the water in motion. This would make a very good project for the new Cairo Archaeological Museum at Giza, to demonstrate to tourists how the Sphinx Moat worked in its original state as an ingenious example of ancient hydraulic engineering.

Figure 6.39. This view shows the swirling pattern in the rock where the water entered from the channel and then passed to the right into the open Sphinx Moat. The horizontal lines in the Sphinx Moat wall beyond the iron gate show how the standing water ate away at the softer veins in the natural limestone; this created the successive indentations, which are approximately horizontal to the bedrock. It is important to stress that they are not waterlines as such, but are erosion lines in the softer veins caused by the water. The veins are not precisely parallel to the bedrock surface because the limestone table is slightly tilted downward to the east. (*Photo by Robert Temple*)

Figure 6.40. Only if one is given special access to the Sphinx and Valley Temples can one get this view of the continuation of the Sphinx Pit around its southeast corner, where the continuity of the water-erosion patterns is clearly visible. The Sphinx Pit leads up and to the right beyond the metal gate. (The base of the Pyramid of Chephren is at top right.) Around this corner and behind the photographer, a channel leads down between the two temples, different aspects of which are shown in the succession of plates documenting these features, some of which have subsequently been covered over by restoration work. I do not believe any other set of photos of these crucial features has ever been taken. (*Photo by Robert Temple*)

I have looked carefully through the published excavation accounts of Selim Hassan from the 1930s. He is the man who finally cleared the entire Sphinx Pit, which he called the Sphinx Amphitheater, down to the bedrock. I wanted to discover whether there was any evidence that he had encountered a mud-brick

wall on the east side of the moat that might have retained the moat water as an additional barrier placed westward of the Sphinx Temple's west wall. He certainly cleared many mud-brick structures and walls from the Sphinx Pit! But my attempts to discover specific evidence on the east side met with frustration because so much work had been done there by his predecessors, most of which was undocumented, in the careless and lazy way archaeologists had in those days. The east end of the Sphinx Pit in front of the Sphinx was largely cleared by Caviglia in 1817 (but the sand returned), partially by Mariette in 1853, partially by Maspero in 1886, again by Baraize in the 1920s, and finally by Hassan in the 1930s. However, Hassan expressed a great deal of frustration at a wall that Baraize had actually himself constructed in front of the Sphinx, and which Hassan had to demolish before he could proceed. Hassan writes: "We commenced our season's work on October 4, 1936, at a spot lying close to the northern and eastern walls which M. Baraize had built, and which we were forced to demolish before we could get down to our task of excavating." 13

He adds further:

In 1925 M. Baraize was entrusted by the Antiquities Department to carry out excavations there [at the Sphinx] on their behalf. M. Baraize certainly freed the statue from all sides, but instead of clearing the sand away altogether, he erected huge barrage-like walls to hold it back, the demolition of which was one of our most laborious tasks when it became necessary to remove them in 1936–1937. I believe M. Baraize had taken his inspiration from the monuments of the Old Kingdom and built for eternity. 14

The photo of the eastern wall built by Baraize in front of the Sphinx and published by Hassan (reproduced here as figure 6.43) shows a massive structure resembling a fortress, as if Baraize were expecting an attack on the Sphinx from the east by a heavy artillery division. <sup>15</sup>

Figure 6.41. This is the strange cubicle and base carved out of the bedrock at the northwestern corner of the Valley Temple. The base of the temple itself is a continuation of the same bedrock. See figure 6.42 for further detail. (*Photo by Robert Temple*)

Figure 6.42. Detail of the cubicle and step at the base of the northwestern corner of the Valley Temple. The electricians for the *son et lumière* show have laid their cables across it. The two granite pieces roughly jammed in recent years onto the top, in front of modern masonry, rest upon the original initial step downward from the end of the causeway, which constitutes the top of this cubicle. It is clear from this first step that this corner cubicle was a way to go down, either into water or onto steps that led into the passage between the two temples. Such a narrow and obscure descent as this can have been intended only for very restricted access (not unlike that of today!) and certainly would have been inadequate for a procession. This descent was not noticed or mentioned by the excavator Uvo Hölscher in the only book ever published about the Valley Temple, a book I know intimately, since I have co-translated most of it from the German. Nor was it noticed or mentioned by Selim Hassan or Herbert Ricke in their books on the Sphinx and the Sphinx Temple. In fact, no one seems ever to have noticed it before! Can this have been the mooring point for a small boat that made its way around the corner and into the Sphinx Moat? (*Photo by Robert Temple*)

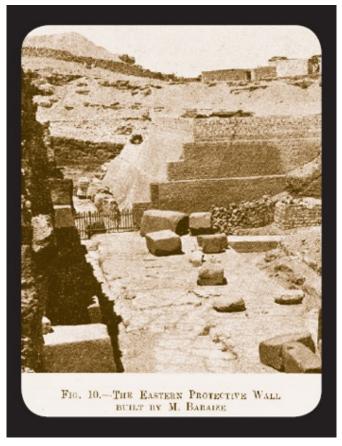

Figure 6.43. Selim Hassan published this photo in his own excavation report to show the "huge barrage-like walls" built in 1926 by Baraize to hold back the sand so that it did not reengulf the Sphinx. The massive constructions are shown in the upper half of the photo. Hassan and his team had the unenviable task of getting rid of these walls. Often it is more difficult to clear away modern structures than ancient ones! (*From Excavations at Giza, 1936–1937, volume VIII*)

The pity is that Baraize's monstrous wall was built on top of the very place where an ancient mudbrick wall would have had to stand to retain water in the Sphinx Moat. In constructing his own wall, and leveling the foundation for it, Baraize would inevitably have destroyed all trace of any ancient mudbrick wall. If anything had survived, it would then have been cleared by Hassan when he got rid of Baraize's wall, for Baraize's wall was too solid and vast to be removed delicately, and an actual assault on it was necessary! So we see that five modern excavators have had a go at the point where the east wall of any moat would have stood. One of them built heavily upon it and the others relentlessly cleared everything to bedrock. No chance of any traces surviving all that! But even in ancient times, activity on that spot was intense. The area was open to the public during Ptolemaic and Roman times, having been entirely cleared by them; this area was the forecourt for the worship of the Sphinx as an idol. The great steps descending to the Sphinx directly over this spot may be seen in figures 6.44 to 6.48. Of the steps, Charles Irby, who visited the Sphinx at the time of the Caviglia excavations and knew Henry Salt, quotes what Salt said to him about the impact they were supposed to make on ancient visitors:

I must beg you [the reader] to imagine yourself fronting the face of the sphinx, at a considerable distance, and nearly on a level with the lower part of the face, and also with the ground adjoining the animal [he refers to the mountains of sand on all sides that have now been cleared away]. As you advance, you find at some distance from the paws, a flight of steps which lead some depth below the paws to the base of the temple [he means the space with the altar, then called "the temple," as the Sphinx Temple itself was still unknown]. Mr. Salt is of opinion that this descent by steps was meant to impress the beholder (after having first viewed the sphinx at a distance on a level) with a more imposing idea of its grandeur, when he views the beast in its full magnitude from below. 16

And even before Ptolemaic and Roman times, the area was cleared by the New Kingdom pharaoh Thutmosis IV when he erected his Dream Stela between the Sphinx's paws (see figure 3.3). So over the past 3,400 years, there have been at least seven serious attempts to clear the area east of the Sphinx, where any extra retaining wall for a moat would have stood in the Old Kingdom period.

The irony of all this is that it was Selim Hassan who in 1936 finally cleared the Sphinx Temple, which was farther east. Its existence was unknown even in the New Kingdom, when it was totally buried in sand and forgotten. This subject is discussed more fully in *Egyptian Dawn*, which includes an account of important discoveries made by myself and a colleague within the Sphinx Temple, to which we were given special access by the Egyptian Supreme Council of Antiquities.

Another crucial fact about the Sphinx Moat is that from the earliest times in the Old Kingdom, much of the rainwater from the east slope of the Giza Plateau was fed into it by a prominent drainage channel. This is remarkable evidence in favor of the existence of a moat being recharged with as much as possible of the rainwater and flash-flood water from the occasional downpours that even today Giza experiences once in a while, and that were more common in Old Kingdom times, when the climate was milder. The existence of this drain has been constantly mentioned by Zahi Hawass in recent years in the context of his friendly dispute with Rainer Stadelmann as to who carved the Sphinx, Pharaoh Cheops or Pharaoh Chephren.

Figure 6.44. This is the only surviving image that shows us the full grandeur of the gigantic stairway leading down to the Sphinx in Roman times to enable the public to come and worship the Sphinx as an idol, and pray to it and make offerings. This drawing, by Henry Salt, shows us the view as seen from the Sphinx itself, with Cairo invisible in the distant background, and the Mokkatam Hills beyond it at the horizon. This drawing was made in 1817, when Caviglia was clearing the Sphinx (men carrying away sand in baskets on their heads are at right). The Sphinx Temple was still unknown at this time and is actually underneath the stairway. The large rectangular mound at the right of the stairway, covered in a hill of sand, covers the right half of the Sphinx Temple (as still seen in figure 6.50, the aerial photo taken in 1926) and the Valley Temple, the latter of which was more or less known to be some kind of covered ancient structure but was not excavated or explored yet. The entire stairway seen here was demolished, and not a stone of it remains, because of the need to excavate the Sphinx Temple beneath. Although it cannot be seen clearly here, to the left of this stairway in this view, along its northern edge at the front, the stairway did not continue to the cliff face, but there was a horizontal passage leading to something underneath, possibly a passage heading northward and descending to a small subterranean chamber. This was never explored. In figure 6.47, which is a ground plan of the stairs and paws of the Sphinx as measured and drawn by Henry Salt, this horizontal side passage is clearly shown, culminating in a left turn marked by Salt "supposed door" and leading to an unknown destination. Since Salt measured the location of this door so carefully, it should be possible to identify that location precisely today by doing measurements on the ground. No one has ever done this, but it is clear that the location is above the northwest corner of the Sphinx Temple, and it may mean that one small section of that structure was known and reached by a shaft at this time. This accords with the findings of myself and my colleague Professor loannis Liritzis, in our official dating investigation of the Sphinx Temple, that a small section of the Sphinx Temple just inside the eastern wall was accessible by shaft during late times. Thus, two small ancient exploratory shafts seem to have reached the Sphinx Temple many centuries after its burial by sand around 2000 BC, resulting in intruded material at one location, though the one we investigated was extremely small and restricted to a tiny area, and the one suggested by Salt's drawings was probably similar. Precise measurements on the ground could give us the location for Salt's "supposed door," and then it would be possible to identify which tiny section of the subterranean structure may have been accessible to the Ptolemies and the Romans and perhaps used as a chamber or crypt in connection with Sphinx ceremonies. This drawing comes from Operations Carried On at the Pyramids of Gizeh in 1837 by Colonel Howard Vyse and John S. Perring, London, 1842, third appendix volume, plate opposite page 113. (Collection of Robert Temple)

Figure 6.45. A photo of the Roman steps leading down to the Sphinx (which is behind the camera), taken prior to 1936 and published by Herbert Ricke in *Der Harmachistempel des Chefren in Giseh* (*The Harmachis Temple of Chephren at Giza*), in *Beiträge zur Ägyptischen Bauforschung und Altertumskunde*, ed. by Herbert Ricke, volume 10, Wiesbaden, 1970. The main steps are on the right. Behind and beneath the minor flight of steps on the left was a passage that was never fully explored. All these steps are now entirely demolished.

Figure 6.46. After the broad Roman steps down to the Sphinx from the east had been removed (see figures 6.44 and 6.45), these older steps were found underneath. Uncredited photo reproduced in Herbert Ricke's *Der Harmachistempel* (1972), plate 4b.

These too have been removed, and no trace remains of any of the steps.

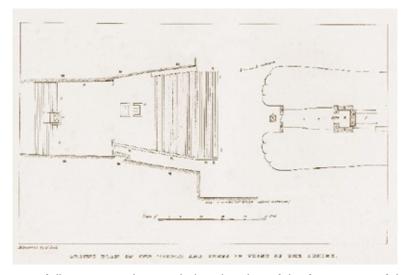

Figure 6.47. This is Henry Salt's carefully measured ground plan drawing of the front paws of the Sphinx (at right) with the altar and stelae between them, facing the now vanished stairway leading down to the Sphinx and dating from Roman times. Salt's view of this stairway, with my extensive caption explaining it, is shown in figure 6.44. The stairway was dismantled and demolished entirely when the Sphinx Temple beneath it was excavated, and not a stone of it now remains. The sections of stairs were separated by platforms containing altars, which explains the curious rectangular structures in the plan. At the bottom of this plan's drawing of the stairs, along the north edge of the bottom of those stairs, was an indented horizontal passage (marked "N") leading to a "supposed doorway" heading north, which was never explored. This probably led to a ladder or small stairway leading to a crypt excavated by a narrow shaft in the northwest corner of the Sphinx Temple, where a chamber may have been used by officiants of ceremonies connected with the worship of the Sphinx at this time.

My colleague Professor loannis Liritzis and I discovered a similar small area elsewhere in the Sphinx Temple against the interior of the eastern wall, which had been penetrated by a later shaft, where intruded material had been left. There is no doubt, however, that the existence of the Sphinx Temple as a structure remained unknown in antiquity after 2000 BC, despite these two apparent shafts reaching tiny portions of it, which must have appeared to be remnants of tombs and were not comprehended as being parts of a temple. (I do not believe the one we found was still accessible by the time of the Ptolemies and the Romans.) This drawing is found in *Operations Carried On at the Pyramids of Gizeh in 1837* by Colonel Howard Vyse and John S. Perring, London, 1842, third appendix volume, plate opposite page 110. (*Collection of Robert Temple*)

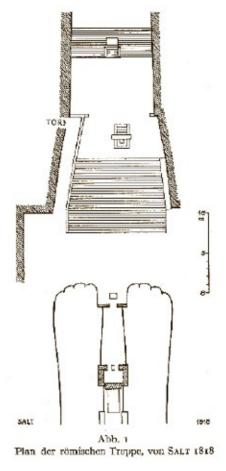

Figure 6.48. The plan of the descent of the Roman steps toward the Sphinx, whose front paws are at the bottom of the picture. This is the plan as published by Herbert Ricke, who took it from Henry Salt's drawing as published in 1818. Directly beneath the Roman steps was the still undiscovered Sphinx Temple. At left, there is a small opening, and the German word *Tor* followed by a question mark; *tor* means "door."

Figure 6.49. This is the corner inside the eastern end of the Sphinx Temple where an intruded shaft led down to the floor level. The dating results obtained by my colleague Professor loannis Liritzis confirmed that this location had been reached by a late intruded shaft. The Sphinx Temple is discussed at length in my book *Egyptian Dawn*. (*Photo by Robert Temple*)

Figure 6.50. This is an aerial photo of the Sphinx taken by the British Royal Air Force on September 28, 1926 (as we know from the information on the back). This image has never been published, as far as I know. This is probably the best photographic evidence to survive of the gigantic barrage walls constructed by Baraize earlier in this same year to hold back the engulfing sand. As can be seen here, his major effort was to prevent the sand from pouring in from the north (on the right in this photo) and the east (the foreground in this photo), since the southern portion of the Sphinx Pit had been completely cleared by him and the portion of the Chephren Causeway beside it had also been cleared. It is remarkable that at this late date, the remainder of the Chephren Causeway was completely covered by sand and was invisible. This photo provides graphic evidence that the Sphinx Temple in front of the Sphinx was still completely unknown, covered in a vast hill of sand. Above and behind the Sphinx Pit, which has been cleared to the bedrock at the back, Baraize has erected strong walls to stop the sand pouring in from the west. All these overwhelming perils of sand were not eliminated until 1936, when Selim Hassan, with hundreds of laborers and railway tracks (see figures 3.11 and 3.12), finally carried it all away in one of the most Herculean clearance efforts in the history of world archaeology. At that time, in clearing the mountain of sand seen here in the foreground, he discovered and cleared the Sphinx Temple underneath, which had been lost beneath the sand and forgotten no later than 2000 BC (which was the end of the Old Kingdom period). This is one of the most historically important photos ever taken of the Sphinx, and I bought it from a dealer for only £2.99. Sometimes in life one gets a bargain. (Collection of Robert Temple)

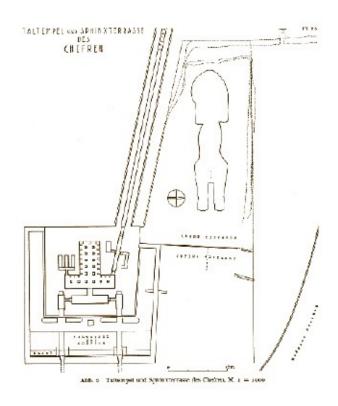

Figure 6.51. "Before." This drawing shows the Sphinx and the Valley Temple as they were known prior to 1936, and the excavation by Selim Hassan that revealed the entire Sphinx Temple in the empty space shown here in front of the Sphinx, which had been covered by a mountain of sand for four thousand years. Compare with figure 6.52 adjoining, which shows the view "After." This drawing is figure 2 on page 5 of Herbert Ricke's Der Harmachistempel des Chefren in Giseh, Wiesbaden, 1972.

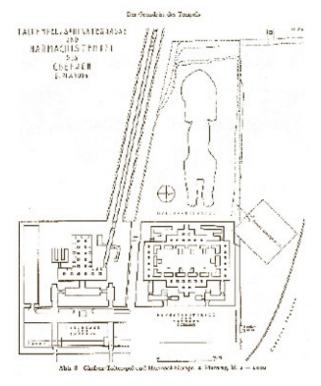

Figure 6.52. "After." This drawing shows the Sphinx with the Sphinx Temple in front of it, as excavated in 1936 and unknown prior to that. This drawing is figure 8 on page 19 in Herbert Ricke's book *Der Harmachistempel*.

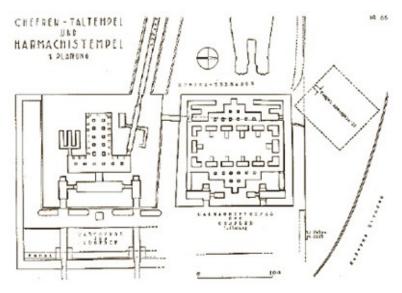

Figure 6.53. This plan from Herbert Ricke's excavation report (in German) of the Sphinx Temple (which he calls the Harmachis Temple) shows very clearly the bedrock barrier at the top of the North Trench, at the right of the Sphinx Temple (seen in figure 6.21). It also gives an accurate location for the small New Kingdom Temple of Amenhotep II, seen in figures 7.3 to 7.5. Although that small temple gives the superficial appearance of having been plunked down more or less at random, in reality it was placed in visual relation to the Great Pyramid, as demonstrated by the photo in figure 7.3. The paws of the Sphinx are at top right. The building on the left is the Valley Temple, and the structures shown in front of it are its quays. The quays of the Sphinx Temple, visible in the old photo in figure 4.2, have been covered over again with sand, and Ricke was unable to draw them because his excavations did not extend that far. *Taltempel* is the German word for Valley Temple. By *Sphinx-Terrasse*, Ricke means the Sphinx Pit, which he calls a terrace.

Figure 6.54. The central court of the Sphinx Temple, seen from the north and looking directly south. The north wall of the Valley Temple rises beyond in the background. Reproduced from Herbert Ricke, *Der Harmachistempel*, Wiesbaden, 1970, in which it is plate 14a.

Figure 6.55. A view of the southeast corner of the Sphinx Temple as seen from the roof of the Valley Temple. Along the bottom of the photo, in deep shade, is the conduit for the water that led into the Sphinx Moat (toward the left) from the Nile inundation floods that would have reached to the place where the people are walking. (*Photo by Robert Temple*)

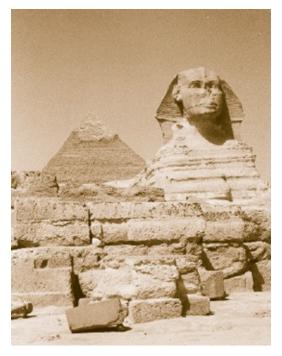

Figure 6.56. This photo, which I took inside the Sphinx Temple, shows two granite blocks (the slightly pink blocks lying on the bedrock) lying loose and abandoned, left perhaps from some lost part of the structure. The two blocks are far from any obvious construction made of granite. There is no ready explanation for their presence in the midst of this limestone edifice. The one in front was presumably left there subsequent to Selim Hassan's excavation. Ricke does not comment on these anomalous blocks, although he carried out subsequent excavations at this site. The Giza structures have many such anomalies and few convincing

As I described earlier in this book, at the 2000 Congress of Egyptologists in Cairo, Stadelmann was giving his paper about the Sphinx having been carved by Cheops (we have already seen in chapter 4 that Stadelmann dismissed the possibility that the face of the Sphinx could possibly be Chephren's), when Hawass got up from the audience, took the microphone from Stadelmann, and said it was impossible that the Sphinx could have been carved by Cheops. Hawass pointed out that there was a prominent rainwater drain connected with the Chephren Causeway that emptied directly into the Sphinx Pit. The implication was that Chephren would never have constructed such a drain and allowed rainwater to pour into the Sphinx Pit if Cheops had already dug out the pit and carved the Sphinx. It would have been too impolite and an insult to allow wastewater to desecrate the site. Therefore, the Sphinx cannot possibly have been carved before the time of Chephren. Of course, that leaves the embarrassing question of why Chephren would want to desecrate his own site! But presumably it would be more polite to do that than to desecrate an existing site, and it would be his own business.

The drainage channel leading into the Sphinx Moat is about 6 feet wide and 4.5 feet deep, so it was a major construction intended to bring considerable amounts of water down into the moat. It was eventually blocked at some later stage by pieces of granite. It is described by Paul Jordan (who prefers to call Chephren by his Egyptian name of Khafre) as follows:

The Khafre causeway was equipped with drainage channels which are interesting to us now because they indicate that rainwater run-off was an essential provision of the pyramid complex. We are accustomed to think of Egypt as a very dry place, but even today, in times that are drier still than were the days of the Old Kingdom, rains can sometimes come and cause considerable damage in a context where they are not routinely expected. Evidently the monuments of the Giza necropolis needed precautions against rain. On the north side of the Khafre causeway, there is a ditch (2 m. wide and 1.5 m. deep) that forms a demarcation line between the pyramid complexes of Khufu [Cheops] and Khafre. This rock-cut ditch was large enough to channel a great deal of rainwater when heavy rains occurred. It is cut into by the corner of the Sphinx enclosure, and—were it not blocked at this point with pieces of granite—would allow water to pour in quantity into the basin out of which the Sphinx body was carved. <sup>17</sup>

Jordan does not mention that if rainwater still poured down the plateau today at the rate it obviously did in the past, the blockage by the pieces of granite would cause a real mess, with the water being diverted all over the place. The drain was probably blocked either during the New Kingdom or during Ptolemaic/Roman times, at both of which eras the Sphinx Moat was open and needed to be kept dry for religious observances at the feet of the statue. By these times, the climate must already have become considerably drier. It is obvious that the granite blocks are not original, since no one would build a long channel all the way down the side of the causeway (which is made of limestone blocks) only to render it ineffective for its purpose at the very end, causing all the work of its construction to be wasted. At some later date, somebody wanted to stop the water pouring into the moat, whereas originally the purpose to divert water from the plateau into the moat is entirely obvious.

Far from being of importance only in the Cheops-versus-Chephren controversy (which may be irrelevant anyway), the rainwater drain that leads directly into the Sphinx Moat makes it clear that from at least the time of Chephren in the Fourth Dynasty, the recharging of the moat with as much fresh water as possible was considered to be such a high priority that vast trouble and expense were lavished on the

construction of a long stone drain leading into it from high up on the Giza Plateau. It seems not so much an act of desecration of a monument as a technique for keeping the moat full, draining into the moat whatever rainwater might be available during the period of the year when the Nile inundation had receded.

And this brings us to the subject of the upkeep of the moat generally, which will in turn explain much that is strange about the apparent signs of severe water erosion in the Sphinx Moat, many of which are vertical. If we look at my photo in figures 6.57 and 6.58, we can see these vertical fissures that appear to have been scoured out of the rock walls of the Sphinx pit by water cascading downward. It is not strange that West, Bauval, and Hancock have drawn the conclusion that these vertical scourings must have been caused by vast torrents of rain pouring down the slopes in remote antiquity when there was supposed to have been a rainy environment in Egypt, prior to 10,000 BC. (This rainy environment may or may not have existed and is disputed.) After all, what else could have caused them?

Let us think about the problems of maintaining a sphinx moat. There you are with your huge moat on the edge of the desert, and what are your problems going to be? What was it that happened so repeatedly to the Sphinx over the millennia? It was always getting covered with sand. And that is the problem for your moat! Sand! (Technically speaking, sand is only a casual term; what you find at Giza is really fine desert dust rather than the coarse sand grains that are familiar to us from beaches.) So what do you have to do, over and over again? You have to dredge the moat. And to do that, you are continually dredging at the sides, hauling up the sand from the bottom of the moat and letting all the excess water pour back into the moat in powerful torrents. You are, in fact, creating artificially and in intensive form the same coursing of water down the sides of the moat that is postulated for the "ancient rain" theory. But you don't need rain, you need only sand, because the sand blowing into the moat with the wind is sufficient cause to motivate your dredging and your scouring of the sides of the pit with descending cascades of water, over and over again until the rock is gouged out in just the way that we see now.

Figure 6.57. Olivia climbing up the vertical crevasse in the south wall of the Sphinx Pit, which I believe was gouged by centuries' worth of water pouring down from dredging operations in the continual battle to dredge the windblown sand out of the Sphinx Moat during Old Kingdom times. (See the crevasses also in figure 6.58 below.) (*Photo by Robert Temple*)

Figure 6.58. To the left is the rear of the Sphinx, in the center is the Sphinx Moat on the southern side, and to the right is the southern cliff wall of the Sphinx Moat. The horizontal erosion along the sides of the cliff in the veins where the limestone was weaker was caused by water lying in the moat for centuries during the Old Kingdom. The separate vertical erosion would have been caused by water pouring down the sides during the process of dredging the windblown sand out of the moat on countless occasions over the same period. (*Photo by Robert Temple*)

You don't need those extra seven thousand years, you don't need Atlantis, you don't need theories about prehistoric climate changes: all you need is sand blowing in the wind, a ditch full of water, and some men with some basic dredging equipment.

Now we can appreciate also the differing patterns of erosion. The vertical fissures in the sides of the Sphinx Moat are from water coursing downward both from dredging and, of course, from rainwater and flash-flood water. (Flash floods may seem anomalous to people who have visited only briefly as tourists, but they are common in Egypt, and in the Valley of the Kings many tombs such as that of Rameses II have largely been destroyed by them. The Old Kingdom dam at Wadi Garawi, east of the Nile, which I have studied intensively and which I will discuss in a future book, was destroyed by an enormous flash flood, and that gigantic dam was of truly enormous strength and bulk.) But there are other patterns: we have already seen that there was standing water in the passage between the Sphinx and Valley Temples, which was of course horizontal. And on the body of the Sphinx itself, there are no great vertical scourings such as there are on the walls of the pit, but rather there are horizontal patterns of erosion, as one would expect on a giant statue sitting in the middle of a moat and constituting an island. The chest and sides of the Sphinx are so prominently scoured horizontally with what appear to be multiple water levels (see figures 2.16, 2.19, 2.25, 2.26, and 2.29 to 2.31), like those along the base of the Valley Temple's north wall, that I am frankly amazed that no one has ever previously pointed out that the statue seems to have sat for long periods in water whose level varied. These horizontal streaks, where the stone has so clearly been eroded in a perfectly horizontal manner (which cannot be as a result of wind!) at multiple levels, are some of the most prominent features of the Sphinx. But even the ancient-rain theorists have never called attention to these patterns. Geologist Robert Schoch published a book entitled Voices of the Rocks in 1999 supporting John Anthony West's thesis. This book contains a disappointing chapter about Schoch's study of the Sphinx. In it, he actually says that "vertical crevices" are "well developed and prominent on the body of the Sphinx and within the Sphinx enclosure." 18 Certainly they are prominent on the walls of the Sphinx Moat, but not on the body of the Sphinx, which is marked instead by horizontal crevices so prominent that they cry out for attention. Schoch, however, does not mention these features at all! His book lacks sufficient references. It is a pity, because he does have some interesting ideas, and I agree with him about some things. For instance, he is convinced that the head of the Sphinx has been recarved:

From the first time I saw the Great Sphinx, and particularly after I was allowed to inspect the head firsthand and up close, I have been convinced that the Sphinx's current head isn't the original. Relatively recent tool and chisel marks, as well as the appearance of the stone itself, indicate that the current head is a recarving from an original (which may have represented an animal rather than a human). This recarving hypothesis also helps explain the head's obviously small size in relation to the body, a disruption of proportion unusual in Egyptian monuments. 19

I certainly agree with all this most heartily, though Schoch then suggests that the head is that of Pharaoh Khafre (Chephren), which it does not resemble in any way, as we have already seen. But Schoch also correctly criticizes a particularly silly passage about the Sphinx by the Egyptologist Mark Lehner, "who used a computer program to reconstruct the appearance of the undamaged Sphinx and felt that the face 'came alive' when he gave it Khafre's features. In other words, when Lehner made the Sphinx look the way he thought it should, then it looked the way he thought it should. Such reasoning is, of course, circular." And this is not the only folly of Mark Lehner's, for his insistence that a straight line can be drawn joining the southeast corners of the three main pyramids of Giza is demonstrably false, as anyone standing at the southeast corner of the Great Pyramid and looking back at the others can instantly see. Lehner's bizarre drawing of this phantom line may be found in his book *The Complete Pyramids*, <sup>21</sup> where a "back sight" is drawn, as if a conclusive observation had been made with a theodolite. In his comments, Lehner calls this "the Giza diagonal line." I do urge anyone who visits Giza to go and stand at the southeast corner of the Great Pyramid and look back at the smallest of the three pyramids, the Mycerinus (Menkaure) Pyramid. He will see that the southeast corner of the Chephren (Khafre) Pyramid is significantly set back and does not fall on this alignment at all. "The Giza diagonal line" does not exist! It does not exist any more than the face of Chephren on the Sphinx exists.

Another interesting revelation in Schoch's book is that an Egyptologist from Chicago, Frank J. Yurco, has the same idea that I have about the Sphinx having sat in a moat, although we formulated our ideas separately, and I have never read anything of Yurco's or even seen any publication of his. Schoch disputes Yurco's ideas, although he does grant that the Nile water would have reached the Sphinx "at least on occasion." One reason he advances for dismissing the idea of a Sphinx Moat is that there would be "greater wear" on the paws than is found. But that is an entirely unconvincing statement, for the paws are well known to be wholly covered in reconstruction blocks and were rebuilt in this way in Roman times for the obvious reason that they were so extraordinarily worn away! Schoch does not give any references to Yurco's publications, which is unfortunate, so I have never been able to find them or to consult them.

There is one other major point in Schoch's book that should be mentioned. He says that he determined through his geological investigations of the Sphinx Pit that there was deeper erosion to the north, south, and east of the Sphinx in the floor of the moat than there is to the west. His discovery substantiates the hypothesis of a moat fed from the east by the Nile. The west end of the Sphinx Moat on the side of the pyramids would have been spared the onrush of the incoming waters and would have eroded less, since the Sphinx itself would have acted as a barrier to protect that end of the moat from water surging in. Also, as the water would have been far more stagnant at that dead end of the moat, sand blowing into the moat would have been less stirred up and would have tended to remain stationary there, thus providing a surface cover. Dredging could never have removed all the sand from the moat, and some would always have settled back. The sand falling back into the west end would have been "dead," in the sense of never moving or shifting around. The wash from the incoming water as it came in from the east would swish extra sand toward the back, western end, where it would tend to collect to a greater depth than elsewhere,

and thus the sand there would always have been much deeper than in the north, south, and east portions of the moat. Bottom erosion would therefore *have to be* less at the west end of the moat. Schoch's discovery thus provides a major geological support for the Sphinx Moat hypothesis.

The two differing patterns of apparent water erosion in the Sphinx Moat are thus found in the two different places where one would expect them and differ in the ways that one would also expect. If we had huge vertical scourings on the Sphinx itself such as we have on the walls of its moat, there would be a problem. But everything accords with the simple explanation that in Old Kingdom times the Sphinx was an island sitting in the middle of a moat with its back and head sticking out of the water. This can explain the ancient reference in the previous chapter to the body of Anubis at Giza being "concealed" as he lies in his crouching position. We might also find echoes of this situation in Utterance 213 of the Pyramid Texts, where we are told: "Your arms are Atum, your shoulders are Atum, your belly is Atum, your back is Atum, your hinder-parts are Atum, your legs are Atum, your face is Anubis."

Atum was the creator god of the Egyptians, who emerged from the watery abyss and chaos of the primeval waters as an island. He manifested himself as an "Island of Fire" in the midst of the water on the occasion of the first sunrise and "emerges from the Akhet [horizon]."<sup>26</sup> This accords with the facts that the Sphinx faces due east on the equinox, facing the sunrise, and that the later name of the Sphinx was Horemakhet, or Horus-of-the-Horizon, and was thus associated with the *akhet*, or horizon, that was first manifested in the initial sunrise of the creator god himself. (A great deal more discussion of this subject is found in the next two chapters.) The crouching guardian of the necropolis, Anubis, thus also represented Atum, and faced the sunrise of the first creation, manifesting himself as the primeval Island of Fire in the midst of the Lake of Fire, of which we hear so much in the Pyramid and Coffin Texts as a central feature of the netherworld.

We have definite proof that the Sphinx was associated with Atum from the Dream Stela, which gives the name of the Sphinx in New Kingdom times as Hor-em-akhet-Kheperi-Ra-Atum. (Hor-em-akhet means Horus-in-the-Horizon, referring to the eastern horizon of sunrise. Kheperi is the name of the rising sun, portrayed as a scarab beetle; and Ra is the name of the sun god in general.) Furthermore, in the *Book of the Dead*, Atum is specifically called "the Master of the Lake" (chapter 3, line 2).

Having considered the work of Robert Schoch, we must now take note of the far more elaborate studies of the Sphinx geology by Lal Gauri, who is coauthor of a definitive book entitled Carbonate *Stone*, <sup>27</sup> of which limestone is, of course, the main kind. He is an emeritus professor of an American university at which I was also an adjunct (part-time "visiting") professor from 1999 to 2002. In 1995, Lal and two colleagues published an article in the journal Geoarchaeology rebutting the ideas of West and Schoch about a Sphinx going back far beyond the Old Kingdom times in Egypt. The article was entitled "Geologic Weathering and Its Implications on the Age of the Sphinx." Lal and his colleagues pointed out that the assertion by West and Schoch that the weathering of the Sphinx and its pit was extremely ancient was groundless, and that there was no need for frequent and heavy rain to have caused the erosion that we see. However, excluding rain is not the same as excluding water! (Everyone admits some rain, but not enough.) They then explain complex details of how erosion takes place in limestone rocks, concerning microscopic pores and so on. Dew (still common at Giza) enters into these at night, temperature differentials work away at the delicate stone, and it flakes and erodes. These processes are still taking place today, as they clearly demonstrate. They also point out that the Giza Plateau is riddled with small caves caused by water flowing through the rock over geologic eons, and then when the Sphinx Pit was excavated, many of these were exposed and the patterns caused by water erosion revealed, having been there all the time underneath the surface. As they put it in conclusion: "The deep channels in the walls of the Sphinx ditch, which [West and Schoch] consider as having been formed by the running water [of "ancient rain"], are actually caves, formed by the underground water in geologic antiquity." 29

There is no doubt that this is true. But being true is one thing and being the whole truth is another. Lal and his colleagues acknowledge that further erosion of these exposed underground watercourses and caves then took place. But they think this was caused entirely by dew. My proposal in this context is simple: there was plenty more water vapor at hand for these microscopic erosion processes that arose from the Sphinx Moat, and furthermore, there were the vertical scouring effects of the dredging, as I have explained, and the horizontal processes of the varying moat level itself, which rose and fell from time to time over the course of the centuries of the Old Kingdom during which it existed.

Lal and a colleague give a more elaborate account of the Sphinx issue in the book *Carbonate Stone*, which appeared four years later, in 1999. In this book, much more detail and many more illustrations are available. It is, in fact, a classic source that anyone interested in this subject must consult. I shall not attempt to summarize the complex material presented in *Carbonate Stone*, much of which is concerned with the highly technical details of pore size in the rock and what the implications of this are for erosion and durability. Lal was, after all, part of the team who worked (together with Mark Lehner and Zahi Hawass) on the great Sphinx Conservation Project. In this book Lal and his colleague repeat:

The evidence used by the authors of the new theory [West and Schoch's "ancient rain" theory] is based upon interpretation of geomorphological features and seismic data. We show in this chapter that deep channels in the walls of the Sphinx ditch that they consider as having been formed by running water are actually caves formed by the underground water in geologic antiquity. . . . Thus, they misinterpreted the geological features that are the basis of their theory. 30

I think we must accept these conclusions and realize that rain is not the answer. It is helpful also to know that the microscopic erosion processes within the stone, explained in such detail by Lal and his colleagues in their publications, have gone on continuously from antiquity to the present. However, all the conclusions reached by Lal and his colleagues are by no means incompatible with the Sphinx Moat. Indeed, the existence of a moat provides the additional moisture needed to bring forward the normal microscopic erosion processes within a reasonable time frame. The vertical scouring caused by dredging would have accentuated the preexisting vertical fissures caused by the underground water, which, although they may already have been there to some extent, would have been deepened. And the horizontal erosion patterns on the Sphinx, which owe nothing to descending water of any kind, were caused not only by moat levels rising and falling, but by the microscopic erosion processes greatly accentuated by genuine soaking in a moat, its withdrawal when the level sank, and its repetition when the level rose, with the weakening effect on the stone that would have resulted. (There would have been a problem of "rising damp," or moisture oozing upward, within the Sphinx body in addition to extra microscopic erosion processes.) In other words, all the arguments put forward by Lal Gauri to counteract the ancient-rain theory are wholly compatible with and mutually strengthening to the Sphinx Moat hypothesis.

And at this point we should turn to the Greek historian Herodotus (fifth century BC), who reports fascinating though highly garbled traditions that further substantiate the idea of an island surrounded by water at Giza:

Chephren also built a pyramid, of a less size than his brother's [Cheops]. I have myself measured it. It has no underground chambers [these were unknown then, but are known today, having been discovered first by the Arabs and then rediscovered by Giovanni Belzoni<sup>31</sup>], nor is it entered like the

other [the Great Pyramid] by a canal from the Nile, but the river comes in through a built passage and encircles an island, in which, they say, Cheops himself lies. 32

We have already not only encountered the tradition that a king lies buried beneath the Sphinx (as mentioned by the Roman author Pliny and in countless subsequent accounts by Arabs and travelers' reports), but we have seen that there was a shaft leading to a burial chamber and extending right down through the body of Sphinx, into which many people have entered, and of which we even have the dimensions, although it was destroyed by Émile Baraize's "restoration" of the Sphinx in the 1920s. I have fully described this in an earlier chapter. Since there is nowhere else on the surface of the Giza Plateau where an island could be said to exist, we must presume that Herodotus's very late account is a garbled tradition of the Sphinx Island, which indeed was fed by water from the Nile, which "comes in through a built passage and encircles an island." Much of what Herodotus wrote about Egypt was lifted from an earlier author named Hecataeus of Miletus, born 549 BC (not to be confused with the better-known but much later author Hecataeus of Abdera, who also wrote about Egypt). Therefore, the account given by Herodotus may have been garbled by him from an earlier account by Hecataeus, to which scribal errors may also have contributed, since the standard of copying of manuscripts at that early date could easily have resulted in a copy of Hecataeus's work, which already contained many serious scribal errors, coming to Herodotus's hands; we need not attribute them to Herodotus personally. Furthermore, because the Sphinx is beside the Valley Temple of Chephren, the association of the Pyramid of Chephren with the Sphinx Island is a natural garbling of the true association of the Valley Temple of Chephren with the Sphinx Island. But this is not the only relevant passage from Herodotus, for he also wrote that the Egyptians claimed the following with regard to the Great Pyramid:

They worked in gangs of a hundred thousand men, each gang for three months. For ten years the people were afflicted in making the road [causeway] whereon the stones were dragged, the making of which road was to my thinking a task but a little lighter than the building of the [Great] Pyramid, for the road is five furlongs long and ten fathoms broad, and raised at its highest to a height of eight fathoms, and it is all of stone polished and carved with figures. The ten years aforesaid went to the making of this road and of the underground chambers on the hill whereon the pyramids stand [i.e., the Giza Plateau]; these the king meant to be burial-places for himself, and encompassed them with water, bringing in a channel from the Nile. 33

This is yet another garbled later tradition, in which confused memories from the past are distorted. The reference seems to be to the Chephren Causeway, or otherwise to the now destroyed Cheops Causeway, or perhaps a conflation of the two. In any case, the Chephren Causeway runs directly to a monument at "the hill whereon the pyramids stand," said to be a burial place of a king, which does indeed seem to have been encompassed with water brought "in a channel from the Nile." In other words, this describes perfectly the Sphinx Island at the very beginning of that great causeway, the rainwater from which even poured directly into the Sphinx's moat.

It is not often noticed either by Egyptologists or by classical scholars that Herodotus does not actually say that the underground chambers to which he refers have anything whatsoever to do with any of the pyramids. He says instead something quite different: that the chambers are inside the *hill*. It happens to be the same hill, or plateau, on which the pyramids also stand. In other words, he is describing underground chambers of the Giza Plateau itself, and definitely *not* underground chambers of a pyramid. The distinction seems to have eluded everyone. This overt ancient evidence *against* the pyramid-tomb theory

is ignored by all Egyptologists, and it would not suit many of them to be forced to take note of it, since it opposes their favorite theory.

As we know, the Giza Plateau is riddled with underground chambers everywhere. So the question we have to ask is: Where in the Giza Plateau, associated with underground chambers and near a giant causeway, can we find an island into which the water of the Nile has been admitted by a channel?

The answer is that there is only one such place: Sphinx Island.

It has often been a subject of speculation why Herodotus never mentions the Sphinx. In his day, it was probably covered by sand up to its neck. It was cleared only some centuries later under the Ptolemies, and the clearance nearly a thousand years earlier in the New Kingdom by Thutmosis IV was long forgotten, its effects long vanished. It generally took twenty years or less (before the total clearance in 1936) for the Sphinx to be covered over in sand, and enough time had elapsed by the time of Herodotus for the Sphinx to have been covered nearly one hundred times. It is difficult to see the Sphinx from the pyramids, especially if it is only a head protruding from the sand, and Herodotus probably was not taken down to its site. This assumes that the accounts of Herodotus are really firsthand accounts, which has been passionately disputed both in ancient times and today, with some classical scholars believing that Herodotus pinched most of his material from earlier authors, so the omission of an account of the Sphinx might merely be a sign of his laziness in copying! The Sphinx Temple at that time was definitely covered entirely and forgotten. We do not know how much of the Valley Temple would have been visible then probably very little or none at all. So there was not much to attract attention from a distance. The simple fact is that at the time of Herodotus, or even the time of Hecataeus, there was no good reason to exert oneself in the heat by walking down the hill, as there were no temples to be seen there, the Sphinx had not yet been cleared, and there was only with difficulty a view of some stone object sticking up out of the sand in the distance, which could not be identified even as the back of a head. Herodotus makes it clear with both descriptions he has given of islands surrounded by Nile water at Giza that he is drawing on Egyptian accounts, for he specifically says: "Thus far I have recorded what the Egyptians themselves say. Now . . . I will add thereto something of what I myself have seen."34

And he then goes on to discuss other things. But another interesting detail of what Herodotus has told us about the Great Pyramid is that Cheops specifically did *not* intend to have himself buried inside but rather in a chamber elsewhere beneath Giza and, according to one tradition, beneath the island surrounded by Nile water. So this is clear evidence against the theory that the Great Pyramid was designed as Cheops's tomb. As I have already said, it is difficult to understand on any logical basis why no Egyptologist seems ever to have noticed this explicit evidence from antiquity *against* the prevailing theory that Cheops built the Great Pyramid as his own tomb. Once again, we encounter a "consensus blindness" situation, where everybody seems to be determined not to see something that is right there in front of his eyes.

When considering these things, it is just as well to take notice of the specific words of the Egyptologist Wallis Budge, who gave a long description of the underworld at Rostau (which he spelled Re-Stau) in describing the Egyptian books dealing with the sun god's journey through the underworld at night. When the sun god's boat comes to the fourth gate, the sun god has to dismount and go across the sands of Giza on a new boat that is dragged; the sun god then

. . . has entered the kingdom of Seker [his spelling of Sokar], who is probably the oldest of all the gods of the dead in Egypt. . . . The main corridor is called Re-Stau. . . . An inscription . . . tells us that it is the road by which the body of Seker enters and that his form is neither seen nor perceived; hence

it is clear that the road by which [the sun god] passed through this Division was supposed to be high up above the dominions of Seker, and that he never saw that god at all. . . . The hidden gods who march in front of the boat [of the sun god as it is dragged over the sand] are few in number, and the names of many of them are unfamiliar; some of them are connected with Osiris, and all of them are under the control of Anpu, or Anubis, and perform some act which helps the boat along. 35

As I have mentioned already, Anpu is the Egyptian name, which we write in the Greek manner as Anubis.

Once again we have the clearest statement that Anubis was presiding in some sense over all these events at Rostau, which encourages us to think that Anubis as the Great Sphinx is being specifically referred to once again.

We can now begin to look at the many references in the ancient Pyramid Texts, Coffin Texts, and others that appear to refer to the Sphinx Moat. We can start with the Pyramid Texts because they are the earliest. And indeed, the earliest of the Pyramid Texts are those that are inscribed on the interior walls of the Fifth Dynasty Pyramid of King Unas (reigned circa 2375–2345 BC).

I once had the wonderful opportunity of sitting for six hours inside this small pyramid, surrounded by the magical texts. There are hundreds of stars painted all over the ceiling. The texts cover all the walls and almost smother the interior, as if all the words that wished to be uttered were clamoring, almost as if they were raising their hands and entreating to be heard, a thousand voices whispering urgently at once: "Listen to me! Listen to me! Not to him! To me!" The name of King Unas is everywhere, in its royal cartouche with the beautiful hieroglyph of the long-eared hare. This was the first time that a pyramid's interior had been inscribed with any texts at all. And suddenly they are all there, like an infestation, and the desperate need to glorify the immortality and resurrection of the king is deafening, overwhelming, insistent: "He will live forever! He will live forever!" The king will rise to the sky, he will become Horus, he will become this god, he will become that god, he will be glorified, he will surpass all the gods. One wonders what suddenly possessed the Egyptians at this period to burst into this riotous affirmation of the eternal life of their dead king. The pyramid is pocket-sized, as they could not build them properly anymore and their civilization was in decline. It has been suggested that the explosion of texts inside the Fifth and Sixth Dynasty pyramids, starting with this one, was a psychological compensation for the fact that the pyramids were so small, just as a small person can have a big temper or enormous ego by way of compensation for his size (such as Napoleon). But despite the tiny size of the pyramid, sitting inside it was a profound experience of timelessness, of the silence of eternity, of the brooding mantras that were intoned from the walls with the long vanished voices of the priests who had recited them here as they slowly led the burial ceremony into this vault where the king's mummified remains would rest, awaiting the fulfillment of his "sure and certain hope of resurrection," to use the words of the King James Bible. The pyramid is closed to visitors, except by special permission, to preserve these very texts on the walls, which elbows and hands and breath could damage. Already the paint on them has faded. But their voice has not faded; it has indeed been regained after 4,350 years. And the pharaoh thus indeed lives on, through these voices, though his remains were plundered and scattered in distant antiquity and the huge and heavy sarcophagus lies open, empty, and desecrated in the silent room where I sat and brooded on his lost world.

In these earliest surviving religious texts from Egypt, we find a fairly clear description of Anubis presiding or "ruling" over Giza, which is called "the Western height." In Egyptian religious and mythological terminology, the realm of the dead is often called "the West," and the dead are "the

Westerners." Osiris, as god of the dead, for instance, "presides over the Westerners." The earliest deity who presided over the Westerners was Khentiamentiu, which means Foremost of the Westerners. He was a jackal, and in fact he was Anubis. By the Fifth Dynasty his identity had begun to become combined with the god Asar (Osiris in Greek), husband of Isis. This terminology occurs hundreds of times, and was standard, in the same way that Christians often refer to Jesus as "the Savior" without actually saying his name, and sometimes call him "the Lamb of God." All religions have certain standard epithets like these that they use over and over again to show reverence and as a kind of shorthand among themselves. There is also a habit in most religions to avoid directly mentioning the name of a divinity too often, as it might be considered as acting too familiar and even irreverently. For instance, Christian priests, when speaking of Jesus in their sermons, very often refer to him as "our Savior," using that or other epithets more often than they actually say the name Jesus or the name Christ. (Baptist ministers are much less restrained and seem to compete to see who can mention the name of Jesus most often within a given period.) More formal epithets such as "Lamb of God" are reserved for hymns, services, and ceremonies. For instance, in the Anglican Church, just before communion, the priest holds aloft the host and says to the congregation as he welcomes them to come forward: "Behold the Lamb of God!" He does not say, "Look, everybody, here's Jesus!" because that would show less dignity. Similarly, one would not address Queen Elizabeth of England as "Liz." So we have to keep in mind that the ancient Egyptians were similar in their use of formalisms and epithets, and that such works as the Pyramid Texts were formal invocations and spells in which the names of divinities had to be varied in a flowery manner for the correct degree of reverence to be shown. Osiris in his underground chamber was "ruler of the Westerners," but Anubis specifically "rules over the Western height":

Thoth, hurry! Announce to the gods of the West and to their spirits: He comes indeed, this [King] Unas, an Imperishable Spirit, decked like Anubis on the neck, who rules over the Western height. 36

This is a very specific allusion to Anubis as the presence who is acknowledged to be "ruling" over Giza, which is the only part of "the West" in ancient Egyptian lore that can be said also to be a "height." (Twice in the Pyramid Texts and many times in later ones Anubis is referred to as Anubis of the Hill or Anubis of the Height.) As for him being "decked . . . on the neck," it is highly likely that the Sphinx had rich hangings around its neck not only when it had its present form (when these hangings are actually depicted in New Kingdom stelae, so that there is ancient pictorial evidence of their existence; see figures 3.21 to 3.23 for examples of the Sphinx bedecked with a neck hanging), but also when the Sphinx was Anubis. The reference to this decorative aspect of Anubis is a further confirmation that an actual statue is being referred to in this text. It would be presumptuous to describe a god as "decked . . . on the neck," but acceptable to describe a statue of the god in that way.

The Pyramid Texts and subsequent ones are full of references to one of the major features of the netherworld at Rostau, the Jackal Lake. I believe that the Jackal Lake, which also had other names, was what the Old Kingdom Egyptians appropriately used as their name for the Sphinx Moat. In fact, like all the sacred entities and places in Egyptian lore, the Jackal Lake also has various epithets. It is also called the Lake of Fire, often within the same passage as its formal name of Jackal Lake or Lake of the Jackal. Other names for it appear to be the Canal of the God, the Canal of Anubis, the Winding Waterway (presumably because if you go along it on a boat, you circumnavigate the island of the Sphinx), the Lake of Life, the Lake of Cool Water, Broad Lake, the Lake of Rushes, the Field of Rushes, and, most often of all, simply the Lake of the Netherworld (or Lake of the Duat, Duat being the netherworld). As for its connection with

rushes, it is highly likely that rushes grew in part of the Sphinx Moat in antiquity (most likely the dead western end where the sand/ dust tended to accumulate), just as they do today at the west end of the winding waterway of the ancient Osiris temple, the Osireion, at Abydos.

A mysterious ancient text known as *The Book of Caverns* describes the netherworld and gives intriguing references to Anubis. Although in its surviving copies this text occurs rather late, appearing for the first time in the reign of King Seti I of the New Kingdom and repeated again on the walls of the Valley of the Kings tomb of King Rameses VI, its contents seem rather archaic compared to some other texts of this kind. The book, copied from the walls of two ancient monuments, was translated into English by Alexandre Piankoff, who says of it: "The whole suggests a gigantic papyrus which has been unrolled the length of the walls." In fact, all the netherworld books inscribed on walls were copied from papyri originally, so they are all older than the dates of their appearance in tombs. Figure 6.39 reproduces a previously unknown engraving dating from 1837 of the sarcophagus of King Seti I (died circa 1278 BC), which is now in London, and which bears such a netherworld text on it; this picture has not been reproduced since its original publication, and, as it is unknown to Egyptologists, I thought I should put it into circulation for everyone to see.

I suspect that the original "gigantic" papyrus from which *The Book of Caverns* was copied was considerably older than its initial use by this same King Seti I, and that it embodies much more archaic lore than many similar texts of the New Kingdom tombs. I asked Professor Erik Hornung about the relative dates, and he believes the illustrations of *The Book of Caverns*, "being richer in iconographic fantasy (which reached its climax in the twenty first dynasty)" and also containing a view of the mythical serpent Apopis, which was no longer entirely that of an evil creature, meant that the book was not as archaic as I thought. I certainly accept his views on the iconography. But I believe that some of the text precedes that iconography and is extraordinarily archaic, drawn from a far earlier text. On the other hand, if one looks at the netherworld text known as *The Book of Gates*, one is struck by the actual text itself having become too fantastic and baroque, a jumble or improvisation, in fact, and wholly lacking the archaic qualities that so strike me in *The Book of Caverns*.

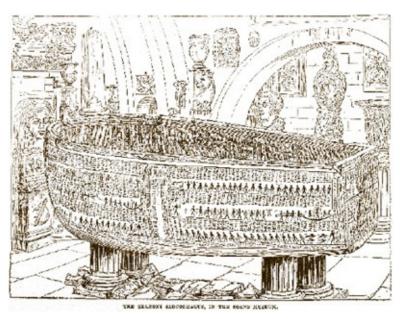

Figure 6.59. The sarcophagus of King Seti I of Egypt (died circa 1278 BC), which was acquired in the eighteenth century by Sir John Soane and is still on display in the Soane Museum (his house, preserved as it was at his death, now open to the public) in Lincolns Inn Fields in Holborn, London, a few minutes' walk from Dickens's Old Curiosity Shop, which still stands. This engraving was published in 1837 in a periodical of the time. Netherworld scenes are depicted on the sarcophagus, accompanied by texts describing the events and phenomena to be encountered there. (*Collection of Robert Temple*)

The Book of Caverns recounts a series of caverns of the netherworld and seems to be based very much at Rostau. There are several suggestive references to Anubis as the presiding presence. At one point, Osiris is described as having "set him [Anubis] in his place without his being able to leave, having been established in the West." 38

This is a very strange way to describe Anubis. It certainly seems to describe a prominent statue, as what else could possibly be meant by being stuck in place and not able to leave? Furthermore, the same text also describes "those who are between his arms." Although Anubis was the master embalmer, corpses being embalmed are not actually held in the arms of the embalmer, and though one certainly cannot insist on it (as it could be just an exaggerated reference to his work as an embalmer), the reference seems to me to be to something quite different. It sounds strangely like the worshipping of the Sphinx at the altar between its arms that went on for centuries and may refer to an earlier stage of this worship in the Middle Kingdom, by which time the moat was dry. It is probable that the moat was filled with water only during the Old Kingdom, and by the time of the Middle Kingdom it had become a dry ditch containing a great deal of sand, which eventually overwhelmed it, so it was only cleared again by Pharaoh Thutmosis (Thothmes) IV as recorded on his Dream Stela centuries later.

This same text of *The Book of Caverns* refers to Anubis four more times in a manner that describes his presiding presence at Giza. The sun god Re (Ra) addresses a cavern of the netherworld, referring to the secret image of the god Sokar, "whose image is great, created by the Netherworld, engendered by the Silent Region, he whose image is unknown, unique mystery hidden from the inhabitants of his cavern. O Behold, I pass near you, I have placed Anubis as your guardian, I give you light."<sup>39</sup>

This is a clear reference to Rostau and to Anubis being "placed as guardian" there. Later, the sun god Re again speaks to "the Cavern of the Forms of Osiris," which is well known to be a feature of Rostau, and enumerates many features of Anubis, referred to repeatedly as "Power of the West." At the end of this litany of praise for Anubis, Re says: "O Anubis, O Anubis! Behold, I pass Anubis, when I pass through those who are in Exalted Earth [the necropolis]. I pass through the mysterious Netherworld."

This indicates that to enter the netherworld at Rostau, it was necessary to pass Anubis, who stood guard at its gate, another suggestion of the presence of Anubis as a statue there.

Further on in the text, in speaking of the dead, we are told, "Their bodies pass by while Anubis is the guard." And Re again speaks to a netherworld cavern where two goddesses lie buried, once again presumably at Rostau: "O the two great and powerful goddesses whose mysterious coffins are guarded. It is Anubis who guards them . . . as well as the Head of Re—mystery of He (who is Lord) of Forms." 42

The Lord of Forms is Osiris, who lies buried at Rostau, and is here identified with the Head of Re, which appears when the sun rises over the horizon. The information about the two goddesses lying buried in a cavern at Rostau is unfamiliar and is probably a stray survival of an early and largely lost tradition predating the Osiris cult concerning the cobra goddess of the north and the vulture goddess of the south, who were so prominent as a pair in the Archaic Period. (It was, after all, Sokar who was the original Lord of Forms, and he became merged with Osiris and essentially replaced by him in the Fifth Dynasty.) The goddesses Isis and Nephthys are constantly shown as a pair on post–Old Kingdom sarcophagi, enfolding the dead pharaoh in their protective winged arms, and they probably perpetuate this motif that we find in this text. (See figure 6.40.) However, I suspect they are not the original form of what is intended here. In my opinion, further research and study are necessary to elucidate this curious reference to the "two goddesses" being buried at Rostau and comprehend what is meant by "their mysterious forms." I am not at all content to let this matter rest, but I do not yet have a sufficient lead to feel that I

have the thread in my hand. One thing that occurs to me at this early stage of my thinking on the matter is that this same place, the Door of Geb (the primeval Earth god) at Rostau, was meant to be guarded by a double-headed lion named Ruti, and this beast with two heads may well be the "mysterious form" concealing the truth about the two goddesses, each goddess being secretly represented by one of the heads of Ruti. (Another name for Ruti is Aker: see figure 1.49.) That mention of those two goddesses is otherwise suppressed in the surviving texts about this place must be a very important clue in itself; they may represent some deeper mystery that was not supposed to be discussed. Another thing that occurs to me is that there are two temples, not one, immediately next to each other at that precise spot. Could the double-temple architectural motif be a hint at the double-headed lion motif, and in turn an esoteric reference to the two great goddesses? Why so much twinning? Unfortunately, this is mythological terrain that remains untrodden and approaches more closely than usual to the underlying mysteries that the Egyptians took such pains to conceal. It is very difficult to know what the name Aker means because there is no other form of it in Egyptian other than the plural form that refers merely to the serpents of Aker. It may be a foreign loan word. Alternatively, it may be connected with the verb *ak*, which means to bend (as in bending one's knees) or to bow. Those are the only Egyptian words spelled *ak*, and although there are words spelled akh, they use a different consonant, and I would hesitate to suggest any linguistic connection. Really, Aker is in my opinion a puzzling name. The name Ruti is not at all puzzling, because it is merely the dual form of Ru, which means lion; Ruti thus means the double-lion or the two lions. One may therefore safely conclude that Ruti is a descriptive epithet of Aker, rather than an actual separate name or a different entity.

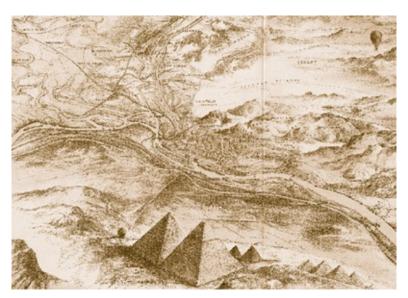

Figure 6.60. This aerial view from a balloon, looking northeast, shows the position of the pyramids of Giza and the Sphinx in relation to distant Cairo in 1882. Cairo, as can be seen, was at that time entirely on the other side of the Nile, whereas today it has crept up to the base of the Giza Plateau itself. This view highlights the position that the Sphinx held as the "guardian of the entrance to the Necropolis of Giza," literally crouching at the entrance. The head of the unexcavated Sphinx may be seen, with the word sphinx written below it. Due to the foreshortening effect of the aerial perspective, the Pyramid of Chephren (with part of its limestone cap intact) here appears larger than the Great Pyramid beyond it, though in reality the Great Pyramid is slightly the larger of the two. The cluster of small pyramids on the right are the Pyramid of Mycerinus and its satellite pyramids; the two small ones that appear to be to the right of the Pyramid of Chephren are two of three small satellite pyramids that actually sit in front of the Great Pyramid (the third being invisible in this view). Not having flown in either a balloon or an aircraft above Giza, I cannot say how accurate this view is, or whether the distortions are due entirely to perspective or to the artist's imaginative powers, or both. (Collection of Robert Temple)

There is a strange reference to an "Earth lion" in Book XI of the Sumerian/ Babylonian/Assyrian Epic of Gilgamesh. A subterranean serpent leaps up from a deep well in the form of an "Earth lion" and steals from Gilgamesh the herb of immortality just as he is about to eat it and achieve eternal life. In my

translation of the epic, published under the original title *He Who Saw Everything*, I called attention to this anomaly in a footnote: "Some esoteric meaning is probably intended, which is not clear." It is not impossible that this "Earth lion" may have some connection with Aker/Ruti of the Egyptians, but I mention this only as a vague and tentative possibility for those who are interested in the occasional points of commonality that seem to appear in Egyptian and Sumerian/Babylonian mythology and religion, which is a subject far from the purposes of this book and which I cannot discuss any further here.

Turning now to earlier texts, Utterance 512 of the Pyramid Texts describes the deceased soul meeting Anubis, apparently at Rostau, since Anubis is there with Geb the Earth god; they are generally described as a pair only at Rostau. Then the deceased is urged to bathe in the Jackal Lake, which is here also called the Lake of the Netherworld. The words of Utterance 512 are:

Figure 6.61. This magnificent and beautiful engraving was published in the Napoleonic series of volumes Description de l'Égypte in 1809. It is a copy of an ancient Egyptian temple wall carving, site unknown (possibly no longer in existence), and shows the sister-goddesses Isis and Nephthys with their angel wings outstretched protectively around the sacred symbol of the god Osiris (husband of Isis), who is seen here as a mummy holding crossed royal and divine insigniae across his chest, with his head replaced by his sacred symbol of the Djed Pillar, surmounted by two plumes with a solar disk in the middle. Usually, in pictures of Isis and Nephthys on coffin lids, the goddesses are identified by their respective names in hieroglyphs above their heads, but that is not the case here. There is an unresolved enigma about whether Isis and Nephthys are intended to be identified with the "two great and powerful goddesses with mysterious coffins and mysterious forms" said to be buried at Rostau, the underworld situated beneath the Sphinx and its two temples. The Pyramid Texts suppressed these references, but they survived in ancient texts copied from a lost papyrus and painted on the walls of the tomb of King Rameses VI at the Valley of the Kings. Anyone who wonders how deities, who are supposed to be immortal, can also be dead or even buried need only remember that Jesus "died and was buried and rose again," as we are told by the Bible. This was meant to emphasize to us that resurrection and immortal life involve the necessity of what we call death, when we leave the illusory world of matter and return home to the eternal world of the spirit (if only temporarily, as some maintain). In order to enter that world, we first have to "die" in the flesh. "Dead" gods and goddesses were surprisingly common in the ancient world. The ancients of various cultures also tended to believe in degrees of immortality, such that, for instance, angels might "fall" and gods like Cronus, the father of Zeus, could be imprisoned in sleep as if dead. Immortality is not as simple as you might think, nor is eternity necessarily absolute in all traditions. After all, even in our daily lives we all say to one another: "I will always love you," or "I will love you forever," or "I will never forget," despite our statements being literally impossible. Everyone, even in religion, is entitled to exaggerate in order to make a point from time to time.

My father has remade his heart, the other [the original physical heart] having been removed for him [it has been removed from his corpse in the process of embalming] because it objected to his ascending to the sky [rising to rebirth] when he had waded in the waters of the Winding Waterway.

(Collection of Robert Temple)

Anubis comes and meets you! And Geb gives you his hand, O my father, (even) he who guards the earth and rules the spirits. I weep deeply, O my father.

Oho! Raise yourself, my father, receive these your four pleasant *nemeset* jars [which contain the corpse's entrails]; bathe in the Jackal Lake, be cleansed in the Lake of the Netherworld, be purified. . . Run your course, row over your waterway like Rē [the sun god] on the banks of the sky. O my father, raise yourself, go in your spirit-state. 44

The Sphinx Moat seems to have been navigated on reed floats and in small boats in religious ceremonies concerning death that involved bathing and rituals of purification. Perhaps the bodies of deceased kings were even bathed in the Jackal Lake prior to their embalming. There are numerous hints of this kind. Or perhaps this was done symbolically with a substitute, as suggested in Utterance 268: "This [deceased] King washes himself when Rē appears [when the sun rises]. . . . Horus accepts him beside him, he purifies this King in the Jackal Lake, he cleanses this King's double in the Lake of the Netherworld."

In Utterance 301 we again read: "Cleanse the King, make the King bright in this your Jackal-Lake, O Jackal [Anubis is addressed here], in which you cleansed the gods." 46

The cleansing that took place in the Jackal Lake may not have involved an actual corpse, but may rather have involved the four jars used for the king's entrails. It seems these were really carried to the Jackal Lake, and possibly the contents were removed and washed in the lake. The cleansing was said to be carried out by a goddess of whom we know little, Kebehut, who is specifically described as being the daughter of Anubis, <sup>47</sup> and who was a "celestial serpent" with the face of a jackal. (Wallis Budge used an older transliteration of her name, calling her Qebhut. <sup>48</sup>) It may be that Kebehut was a special priestess, known as Daughter of Anubis, who carried out the funeral ablution and censing ceremony ("censing" refers to the process of fumigating something or someone with incense from a swinging incense holder called a censer), and that she also represented the goddess Nephthys. In Utterance 515 we are told that Kebehut holds the four jars, removes the dead king's heart, and washes it in the lake, and the deceased king says, "The heart of the great god [Osiris] was refreshed on that day of awakening [the entombment of the corpse of Osiris, who became god of the dead], and she refreshes therewith my heart for me for life; she cleanses me, she censes me. I receive my meal [offerings]."

Kebehut appears again in Utterance 674, where "she refreshes your heart in your body in the house of her father Anubis. Be purified . . . the spirits . . . shall grasp your hand."  $\frac{50}{100}$ 

It seems that the entrails, apart from possibly the heart, were not actually removed from the four jars, but that the four jars were dipped into the lake and filled with water so that the entrails were washed within their jars. This process is described in Utterance 666: "O King . . . take this purification of yours, these four . . . jars of yours which are filled full from the Canal of the God [Anubis], cleanse yourself with them as a god and go forth thence." <sup>51</sup>

It seems that a purification at the Jackal Lake was a necessary part of the ritual for the dead king during the Old Kingdom. Anubis presided over all of this, as Utterance 676 makes clear: ". . . Anubis who presides over the God's [Osiris/ Sokar's] Booth [which was at Rostau] has commanded that you be purified with your eight *nemeset* jars and your eight *āabt* jars which came forth from the Castle of the God [a temple, presumably what we now call the Valley Temple, which appears to have been dedicated originally to Sokar but later to Osiris]. You are indeed god-like."<sup>52</sup>

This same utterance places these events specifically at the Sphinx precinct: "You have your water, you have your flood, you have your efflux [the translation "sap" used by Renouf is probably better] which issued from Osiris [a process that is always described as being at Rostau, underground]. . . . This cold water of yours, O Osiris, is what is in Busiris." <sup>53</sup>

Busiris, as we remember, is the particular region of Giza where the Sphinx is found, and its Egyptian name was Djedu, an Egyptian word that means ghosts. (Although there was a city named Busiris in the Delta, the occurrence of the name Busiris or Djedu in an Egyptian religious text is always a reference to the Busiris at Giza, which may originally have had that name transferred to it by association with the

Delta city in predynastic or early Old Kingdom times. Pliny is our source for the definite information that Busiris was the Greek name of the village beside the Sphinx.)

During the reign of Amenemhet II of the Middle Kingdom, whose face I believe now to be on the Sphinx, a story called "The Tale of the Two Brothers" was written. The washing of the pharaoh's heart in the Sphinx Moat, or Jackal Lake, before the great statue of Anubis, seems to be echoed in the story, in which Anubis himself places the heart of Bata in a bowl of cool water to resuscitate him.<sup>54</sup>

A causeway is also mentioned as being beside the Jackal Lake, as we are told in Utterance 690, where Kebehut, the Celestial Serpent, washes the dead king: "O King, your sister the Celestial Serpent has cleansed you upon the causeway in the meadow, you having appeared to them as a jackal. . . . May you govern the spirits, may you control the Imperishable Stars." 55

This may well be a specific reference to the Chephren Causeway, which runs into the Sphinx Moat. We have previously encountered mention of a causeway beside Anubis in another Pyramid Text.

The Pyramid Texts contain many more relevant references, but there is no need to consider them all. Some references from the Coffin Texts are useful, however.

Coffin Text Spell 551 suggests that a ceremony may have existed in which the Sphinx Island was circumnavigated four times on a reed float or in a small boat. The text, which is merely suggestive, has the deceased say: "I have come to you, my father Rē. . . . I have gone round the watery Chaos four times, . . . I have bathed in the Lakes of the Netherworld, I have washed in the Lakes of the Jackals, I have [sailed in] the bark . . . . Going aboard the bark of Rē." 56

In Spells 33 and 35, we read of the Lake of the Jackal being called the Place of Ferrying: "Welcome, O you whom Osiris has sent. . . . I will cause him to be pure in the Lake of the Jackal among the blessed ones. . . . I will cause him to enter into the Place of Ferrying among the blessed ones." <sup>57</sup>

The deceased bathing in the Jackal Lake is mentioned again in Spell 255: "Promoting a man's double in the Realm of the Dead. Water is upon me, I appear as  $R\bar{e}$ ; water is on my hands. . . . Nephthys has nursed me in the Jackal Lake, I am loosed in the Lakes of Peace, . . . acclamation is made to me by the lords of the West." 58

The location of the Jackal Lake at Busiris/Djedu, that is, the Sphinx precinct, is specified in Spell 292, where the deceased says: "There is opened to me the sacred place at the Lake of Jackals. O you who are over eternity, who are in your windings, prepare a path for me. . . . O you who are in Djedu. . . . It is I who eat the [word missing] which is in Djedu." 59

A terrifying aspect of Anubis presiding over a lake is given in Spell 335, Part II, where the deceased begs Atum to "save me from that god . . . whose face is that of a hound. . . . It is he who is in charge of the interior [or island?] of the Lake of Fire, who swallows shades, who snatches hearts." 60

This image is elaborated later in the same spell: "O Atum... save me from that god... whose face is that of a hound.... It is he who is warden of the windings of the Lake of Fire.... As for this god whose face is that of a hound... his name is 'swallower of myriads.'" $\frac{61}{1}$ 

Here we have the further detail that the lake winds around, an evident description of it encircling its island. Spell 336 repeats this detail. 62

A group of Coffin Text spells, numbers 1165–1185, relate to Rostau, to a winding or bending waterway, and to a presiding deity of the waterway who is known both as Khepri (Khepera), the rising sun whose name was part of the name of the Great Sphinx in New Kingdom times, and Dog-face (an epithet of Anubis). Spell 1185 specifically refers to "the ways by water which belong to Rostau." The

waterway is also called the Lake of Fire, one of the alternative names of the Jackal Lake, and Lustral Basin, because of the purificatory bathing of the deceased's organs that took place in it. As for Anubis, whose giant size is here referred to: "His name is Dog-face, whose shape is big." 64

There is not much of interest in the late texts of the *Book of the Dead*, but there are some interesting references in the Netherworld Texts of the New Kingdom, so many of which derive from Middle Kingdom material, as we have seen already with the *Book of Caverns*. The texts inscribed on the shrines found in the tomb of King Tutankhamun appear to refer to the Sphinx Island in the middle of Jackal Lake as "the Island of Baba" in the netherworld; they have clear associations with Coffin Text Spell 335, and they add further:

O Re-Atum, Lord of the Great Palace, king of all the gods, save thou the King . . . from the arm of this god whose face is that of a dog . . . guardian of the winding of the Island of Fire, who swallows corpses. . . . The Swallower of Millions is his name, he is in the Lake of Wen [Opening]. As to the Lake of Fire, it is between Neref [a strange name, see below; it was on the southern side] and Shenit [sister]. . . . Baba is his name. [The name Baba is another puzzling one. Bābā means to drink, or, apparently, to get drunk on blood, but nothing else.] He is the guardian of the winding of the Lake of the West. 66

The name Broad Lake is used to describe the abode of Osiris-Sokar, another reference to the lake at Rostau. And the cleansing of the heart in the waters of Rostau is twice referred to in a curious way. One of the many epithets known to be used of Osiris at Rostau is Weary Heart. The Tutankhamun texts tell us that the deceased claims: "I am enduring in Busiris . . . the holes are being opened to wash Weary Heart, the mystery of Mysteries in Ro-Setau [Rostau]," a passage that occurs twice. And a third passage says: "I am enduring in Busiris . . . I open the holes to wash Weary Heart, I hide the Mysteries in Ro-Setau." These may simply be references to the washing of the deceased king's heart in a jar in the Sphinx Moat, or they may refer to the letting of water from the moat through some holes down into the subterranean precincts as an ablution intended for the remains of Osiris. Probably it refers to the former, a rite that we have already encountered. This Tutankhamun material, therefore, derives from Old Kingdom times because of the similarity to the vastly older sources, the Pyramid Texts. The Tutankhamun texts also speak of the mysterious presence brooding over the Jackal Lake by saying: "I know the name of this god, it is He who is on his Lake."

The strange name Neref given above as part of the topography of Rostau occurs in the Tutankhamun texts again in the variant form of Nareref, where it is defined as "the Southern Gate of the Mound of Osiris," which is described as being "opposite the lake of the just," thus again clearly mentioning the existence of the lake at Rostau. However, the translator Piankoff is not absolutely certain that *lake* is the correct word, and in a footnote he says an island may really be intended, within a lake. Neref, or Nareref, was transliterated as Naarrutf by Wallis Budge in an earlier era and means "the place where nothing grows."

Osiris is described by Isis in one of the Tutankhamun texts as emerging from the netherworld, presumably again at Rostau, at "the House of the Lake," which is presumably one of the old epithets of either the Sphinx Temple or the Valley Temple. And the topography of Rostau is again referred to as a "city on the water": "Thou travelest in thy barge in this city on the water. He rows in this field close to the body of Osiris. . . . . He [the king] lands at these mysterious castles [presumably the two adjoining temples] which contain the image of Osiris. This God calls above these mysterious castles. . . . The majesty of this

god establishes this city in the Netherworld for these gods."

These many references in the shrine texts of Tutankhamun are very archaic. But by and large, memory of the long-vanished Jackal Lake had faded by the time of most of the New Kingdom texts, and even the archaic tradition mentioning it as a sacred feature in the tradition seemed to have no point any longer to the priests. Whereas the Papyrus of Nisti-ta-Nebet-Taui speaks of "Anubis, the Great God Imyut [the sacred symbol of Anubis], Lord of the Holy Land, He at the Head of the Necropolis," thus giving a correct impression of the great statue of Anubis seated at the entrance to the Giza Plateau even though it no longer existed in its original form, all reference to the presence of water has disappeared.

I should mention in passing that the hieroglyphic depiction of the name of Rostau features coils of rope. I regard these as images of the long ropes used to lower heavy stone sarcophagi down shafts into their subterranean abodes.

When I was working with my wife and a colleague in the Sphinx Temple, Olivia and I both had the same subjective impression. We felt as if we were walking around in an area that for some part of its history had been submerged in water. It has a kind of "underwater" look and feel about it. Of course, this is just a personal feeling, but I thought it worth mentioning, as so few people have ever set foot inside the Sphinx Temple, which has been closed to visitors for much, or perhaps all, of the time since it was cleared in the 1930s. I think it is at least possible that the Sphinx Temple was partially flooded on an intentional basis during the Old Kingdom when the Sphinx Moat existed. This state may have existed only during the inundation months. Looking at the twisting and turning ways inside the structure (see figure 6.15 for a photo from above), I can imagine a ceremony accomplished in small boats or on reed floats that made their way along the interior corridors and bends of the temple on water. In itself, there is nothing improbable about this. And perhaps the reference above to the "city on the water" at Rostau refers to this state of affairs, with the "castles" of the city being the Sphinx and Valley Temples. Perhaps the large "well" in the center of the entrance to the Valley Temple was really a drain, to help drain away the floodwaters from that temple after the inundation receded. It is easier to think of the "well" as such a drain than as a genuine well, with the Nile at least lapping at its doorway and in danger of plunging down it and polluting any true well water. It was this "well" into which the famous huge seated statue of Chephren with the falcon wrapping its wings around his head (now proudly displayed in the Egyptian Museum at Cairo) was thrust in a time of turmoil, thought to be the First Intermediate Period. The priests who presumably wished to save this statue from destruction may have found it convenient to thrust it down a drain that was still full of dirty drainage water, where it could not be seen, rather than into a clear well, where it would have been visible during the plundering of the temple.

One of the traditional names of the god Osiris was Water of Renewal, followed strangely by a determinative sign of a vase. (A determinative sign is a hieroglyph at the end of a word or name that is read not as a letter or syllable but as an indicator of the meaning of a word, such as for instance drawing a picture of a goddess after a name to indicate that the name is that of a goddess; the sign thus determines the nature of the name or word.) This name occurs in the Pyramid Texts inscribed on the walls of the Pyramid of King Pepi I and even survives in the *Book of the Dead*. I believe this refers to the use of the vase containing the heart, which was washed in the moat, bathing in the water symbolizing an act of renewal and rebirth. It was Renouf who made a special point of commenting on this epithet of Osiris in the notes to his early translation of the *Book of the Dead*. Once one is aware of the ritual of the bathing of the deceased king's heart and other internal organs in their four jars in the Sphinx Moat, many hitherto obscure passages in the Pyramid Texts become clear, such as the one in Utterance 509: "My entrails have been washed by Anubis."

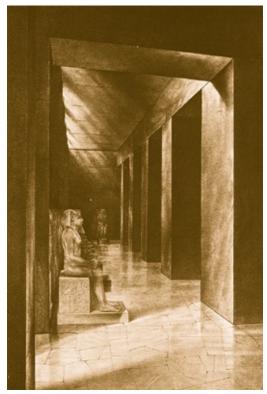

Figure 6.62. This is an imagined reconstruction of the interior of the Valley Temple of Giza. We see here the transverse hall, which runs north to south, at the eastern end of the structure. Here it is called by the name of the Pillared Hall (Pfeilersaal in German). A row of statues of King Chephren is envisaged here, sitting in the tranquil and eternal deathly gloom of faint light filtering in through narrow slits in the roof. The pillars are of solid granite, massive blocks weighing tens of tons each. The floor is of white Egyptian alabaster, called travertine. This is a very evocative view drawn by A. Bollacher and based on the reconstruction by Uvo Hölscher, who excavated the structure fully for the first time. It was published as plate 5 in Hölscher's book, Das Grabdenkmal des Königs Chephren (The Funerary Monument of King Chephren), Leipzig, 1912. Fragments of many Chephren statues have been found in the vicinity, and one large whole one is preserved in the Egyptian Museum at Cairo. It was thrown down a well beneath the temple, probably by priests who hid it there in a time of turmoil to preserve it. The Old Kingdom period of Egypt came to an end with the Sixth Dynasty, when terrible droughts and flood and plagues devastated the country for about 150 years, between approximately 2150 BC and 2000 BC. During this period, social order broke down and mobs rampaged around the Giza Plateau smashing everything, including the statues of Chephren envisaged here. It was at that time that I believe severe damage was done to the original head of the Sphinx, so the recarving that we see today was done from a kind of stump of the natural head. The period when civilization and the rule of law and order returned to Egypt about 2000 BC is the period that we call the Middle Kingdom. The period of turmoil between the Old Kingdom and the Middle Kingdom is known to archaeologists as the First Intermediate Period. (There was a second intermediate period, which separated the Middle Kingdom from the New Kingdom.)

Figure 6.63. A photo of the Sphinx taken at a specific moment in 1936, after Selim Hassan had reconstructed the lappets of the headdress, after he had removed the scaffolding around the head, but before he had erected scaffolding around the main body of the Sphinx to smear more cement over the body cracks that Baraize had largely filled up with cement ten years earlier. In the foreground is the fully excavated Valley Temple. (*Collection of Robert Temple*)

Figure 6.64. A photo circa 1890, showing the Sphinx behind the Valley Temple, only the interior of which was so far excavated.

The Great Pyramid is behind. (*Collection of Robert Temple*)

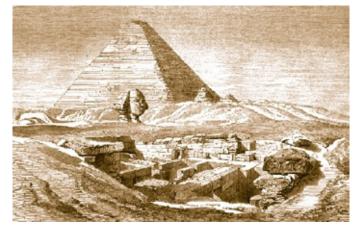

Figure 6.65. This nineteenth-century French engraving shows how Auguste Mariette excavated only the interior, but did not clear the exterior, of the Valley Temple at Giza during the years 1853–60. It is in the foreground, and at that time was called the Sphinx Temple, because the true Sphinx Temple had not yet been discovered. The head of the Sphinx is seen behind, and in the background is the Great Pyramid. (*Collection of Robert Temple*)

Figure 6.66. An old glass-slide photo circa 1870/1880 showing the Sphinx in front of the Great Pyramid, and in the foreground the excavated interior of the Valley Temple, which was cleared during a seven-year period between 1853 and 1860 by Auguste Mariette. (At that time it was called the Sphinx Temple, because the true Sphinx Temple in front of the Sphinx was still covered by sand and was not discovered until the 1930s.) (Collection of Robert Temple)

Figure 6.67. This old photo by Bonfils, probably dating from the 1890s, shows the Valley Temple sanding over subsequent to 1870, when its interior had been excavated by Mariette. Walls made of small stones closely hug the west wall (at rear in photo) and the north wall (right in photo). The Valley Temple during the period from the New Kingdom onward acted as a kind of sand-filled megalithic foundation for inferior structures of small stones and mud brick, which even in this photo have not been fully cleared away. It was only when Uvo Hölscher finally excavated the Valley Temple in its entirety and cleared its outer walls that all

Figure 6.68. Yet another view of the foundation wall of small stones (foreground) built into the eastern end of the Valley Temple's roof. (*Collection of Robert Temple*)

Figure 6.69. Another view of the foundation wall of small stones that was built into the eastern end of the Valley Temple roof. (Collection of Robert Temple)

Figure 6.70. This is how the Valley Temple looked about 1870, after the excavations of Auguste Mariette. The interior had been excavated, but the exterior was essentially uncleared. Furthermore, the eastern face of the structure was covered over with this crudely constructed wall of small stones, which extends also about halfway along the top of the southern wall of the temple and then bends inward as well. The wall was actually a crude stone foundation of a building that stood for centuries on top of the Valley Temple's eastern half. Obviously, no trace of this crude foundation wall survives today. I have placed a highly enlarged version of this photo on my dedicated website supplementary to this book (www.sphinxmystery.info) so that archaeologists can study the fine detail, as the photo has extremely high definition and depth of field and yields a great deal of detailed information about what the site was like prior to the excavations of Uvo Hölscher. (Collection of Robert Temple)

Figure 6.71. This old Victorian glass slide gives a tinted view of the Sphinx seen from the southeast corner of the Valley Temple, at a time when only the interior of the Valley Temple had yet been cleared, and the sand still stood around about it. This was one of the most popular vantage points for photos of the Sphinx taken at that time. (*Collection of Robert Temple*)

Such passages are no longer seen merely as general descriptions of the embalming process carried out symbolically by Anubis, but as a specific ritual carried out in the presence of the giant statue of Anubis in his Jackal Lake. Sometimes the topography is muddled, or at least the religious lore is, and the goddess Isis intrudes onto the scene. The mythological context can be altered and expressed in terms of Isis and her son Horus, as in Utterance 510 of the Pyramid Texts:

I travel the Winding Waterway . . . because I am pure, the son of a pure one, and I am purified with these four *nemeset*-jars [for the internal organs] of mine which are filled to the brim from the Canal of the God in Iseion [sanctuary of Isis, rather than Osiris, in this context], which possesses the breath of Isis the Great, and Isis the Great dries me as Horus.

"Let him come, for he is pure": so says the priest of Rē concerning me to the door-keeper of the firmament [these are probably actual words of the ritual], and he announces me to those four gods [the gods of the four *nemeset*-jars, who were "sons of Horus" or "followers of Horus"] who are upon the Canal of Kenzet.<sup>75</sup>

Kenzet, or Kenset, was another of those names that referred to both a real place (in this case in the very far south, the so-called First Nome district) and a mythological locality. It means the Land Beyond. But there is no need to pursue further all these myriad epithets, their use, and their history in Egyptian tradition at this time.

One could go on gathering up all these confused threads, or scattered limbs, indefinitely. But the essence of the situation is clear. There was a sacred Lake of the Netherworld called Jackal Lake, which had many other names and fancy descriptions, presided over by Anubis, and it was "winding" and also called a "canal of the god." It was at Rostau in Giza. It is mentioned in the ancient texts over many centuries, repeatedly. It was the scene of a sacred ritual of the washing of the internal organs of the deceased king in the four jars that contained them, which were submerged into the water at the edge of the lake, as an act of purification to facilitate his resurrection. I suggest that this was all real, not mythological, and that in Old Kingdom times it took place in the Sphinx Moat, which surrounded the great statue of Anubis, which I choose therefore to call Sphinx Island.

Finally, we come to the most specific evidence of all that the Great Sphinx was once an island. This

evidence has been discovered by excavation within the Sphinx Pit itself. In 1817, when Giambattista Caviglia cleared the front of the Sphinx, he cleared its paws of sand for the first time since the collapse of the Roman Empire. And there he found an inscription in Greek carved prominently on the middle toe of the Sphinx's left paw. The inscription was carved with official sanction in the year AD 166, during the reign of the emperor Marcus Aurelius, to commemorate the Roman restoration of the retaining walls that surrounded the Sphinx. The Sphinx of the Sphinx as being an "island (made) of a rock."<sup>77</sup> When this inscription was found, it was wondered whether the Arrian whose name appears at the bottom of the Greek verse might possibly be the same Arrian as the famous historian of that name, who wrote the life of Alexander the Great called Anabasis of Alexander. (The Greek word anabasis means journey upward, and it was the title the earlier Greek historian Xenophon had given to a famous work of history that he wrote. Arrian was often called in his lifetime the second Xenophon. He paid homage to the original Xenophon by imitating the title of his most famous work.) Although Arrian was a Greek who wrote in Greek, he lived at the time of the Roman Empire, and his honorary Roman name was Flavius Arrianus. He was a personal friend and protégé of the Roman emperor Hadrian (who died AD 138). They met during Hadrian's visit to Athens in AD 126, and Hadrian then took him back to Rome with him and gave him his honorary Roman name personally (Flavius being a forename that could be used only by royal decree), eventually appointing him to be consul of Rome (the highest office under the emperor). Prior to the consulship, in 132 Hadrian had appointed Arrian to be governor of the Roman province of Cappadocia in Asia Minor, where Arrian showed unexpected military prowess and repelled a major barbarian invasion by a fierce and warlike nomadic people called the Alans. Arrian had started life as a peaceful philosopher. He had been a pupil of the famous Stoic philosopher Epictetus (who died circa AD 135), whose chief disciple he was. He published many books of Stoic philosophy based on the discourses of Epictetus and also compiled the famous *Manual (Enchiridion* in Greek) of Epictetus's teachings, which is still popular and highly relevant today. Epictetus was like the earlier Socrates in that he wrote nothing. All the works that we have today by Epictetus, which are extensive, were actually written down and systematized by Arrian as a record of his teachings. One of the first seventeenth-century books I ever bought as a young man, and still one of my most precious for both intrinsic worth and sentimental reasons, is George Stanhope's 1694 translation of the Commentary on Epictetus's Manual by the Neoplatonic philosopher Simplicius. I pored over this work when I was in my twenties and in my phase of intensively studying both Stoic philosophy and Neoplatonism. As Simplicius says (in seventeenth-century English, in which important nouns were capitalized, as they are today in modern German):

The principal Design of this book (if Men would but suffer themselves to be wrought upon by it, and not think it sufficient to give him the Hearing only, but let it seriously affect their Minds, and would reduce [transform] what they read into Practice) is, To set our Souls as Free, as when their Great Father and Creator first gave them to us, to disengage them from all those slavish Fears and confounding Troubles, and other Corruptions of Humane Nature, which are wont to subdue and tyrannize over them.

It is called an *Enchiridion*, or Manual, because all Persons, who are desirous to live as they ought, should be perfect in this Book, and have it always ready at hand: A Book of as constant and necessary use as the Sword (which commonly went by this name, and from whence the Metaphor seems to be taken) is to a Soldier.

The Discourses are lively and moving; and all but the Stupid and Sottish must needs be affected with them.<sup>79</sup>

Clearly, I had no desire to be among the stupid and sottish, so I took the book very much to heart, absorbing at a very early age the crucial distinction it made between "what is in our power" and "what is not in our power," which has enabled me to regard countless vicissitudes of life with a greater degree of equanimity than would otherwise have been possible. I cannot recommend the insights of the work highly enough. Arrian, who had such experience of war, both as a commander who repelled the barbarians and as a magnificent historian of Alexander the Great and his military conquests, clearly gave the *Manual* its particular title on purpose, having very much in mind the soldier's sword as the analogy, as Simplicius points out. One is tempted to hear Arrian humming something like: "Onward Stoic Soldiers, Marching unto War, with the Enchiridion Going on Before." Certainly, the Christian concept of "the Church militant" owes something to this.

There was no other famous Arrian in antiquity. And so, when one speculates on who would have the prestige and authority to inscribe his words on the toe of the Sphinx on the occasion of a great public and official Roman ceremony, one unhesitatingly concludes that it could only have been the historian Arrian, who was one of the highest-ranking retired dignitaries in the entire Roman Empire. Another point to keep in mind is that the inscription was in Greek (Arrian's native language), although the official occasion was a Roman one. One can safely conclude that only someone as famous as Arrian would have been allowed to inscribe something in Greek rather than in Latin to celebrate a Roman state occasion.

Arrian was presumably visiting Egypt and would have been invited to compose a celebratory verse as a courtesy by the Roman governor of Egypt at that time. I think we may safely conclude, therefore, that the verses cut into the toe of the Sphinx were written by the famous historian Arrian. By that time, he had been retired from political activities for twenty-eight years and had returned to his hometown of Nicomedia in Bithynia (Asia Minor) and his main residence, though he must have visited Rome and other parts of the empire from time to time. In Nicomedia, he is known to have become a priest of Ceres and Proserpine. Proserpine was a goddess of the underworld, known in Greek as Persephone. Arrian would therefore have had a particular and specific interest in underworld deities in Egypt, as he was a priest of a Greek underworld deity himself. He would thus have been fascinated by Giza as the most famous necropolis of Egypt. As an expert historian with an encyclopedic knowledge of the past, the content of his verses would have special importance, especially with regard to historical tradition and detail. Everything suggests, therefore, that Arrian the historian wrote the verses on the toe of the Sphinx. And to us, these verses are very important. The inscription no longer survives, as the paws of the Sphinx have been covered entirely with modern "restoration stones." Curse the "restoration"! It obliterates everything! But in 1817, shortly after it was discovered, the inscription was copied down very carefully. In ancient times, Greek was written entirely in capital letters, as lowercase letters had not yet been devised. So we have an engraving of the original inscription in capital Greek letters (reproduced here in figure 6.51), a rendering of it in lowercase (shown in figure 6.52), a translation of it into Latin, and a translation of it into English. All these were published together in the Quarterly Review, volume 19, for April and December of 1818, in London in 1819. There are three English translations of this crucial inscription in existence. Here is the English translation of the verses in modern prose as published by Selim Hassan, and possibly adapted or translated by his assistant, Omm Sety (Dorothy Eady): "Thy formidable form is the work of the Immortal Gods. In order to spare the level, harvest-bearing land, they placed you in the midst of your cavity, as a rocky island, from which they had driven back the sand. They placed you as a neighbour to the Pyramids, for our beholding; not like the Sphinx of Thebes, slain by Oedipus, but as a sacred servant of the divine Leto, who vigilantly guards the good, lamented Osiris, the Sacred Guide of the Land of Egypt."81

Figure 6.72. This is the Greek inscription on the left paw of the Sphinx, dating from the official Roman commemorative ceremony of AD 166, as it was published in 1819 in the *Quarterly Review*. The copy was apparently made by Henry Salt in 1817 at the time of Caviglia's excavation.

```
Σόν δέμας ξαπαγλου τευξαν βεω αίτυ ξοντες,
Φεισάμενοι χώρης πύριδα μαζομένης
Κὶς μέσου ευβύναντες άρουραίσιο τραπέζης,
Νήσου πετραίης Φάμμου ἀπωσάμενου
Γεύτονα πυραμίδων ταίην βέσαν είσοράσσβαι,
Οὐ τὴν Οἰδιπόδαο βερτοπτόνου, ὡς ἐπὶ Θήβαις,
Τἢ δὲ βεὰ Αητοι πρόσπυλον ἀγνοτάτην,
[Εὐ μάλα] τηρούσαν πεποβημένον ἐσβλὸν ἐσβλὸν ἀναπτα,
Γούης Αἰγυπτίσιο σεβάσμων ἡγήτηρω,
Οὐράνων μέγαν αὐτομέδοντα, [βεσισω ὅμαιμον,]
Εἴκελον 'Ηφαίστη, μεγαλήτορα, [βυμολέοντα]
[ ᾿Αλκιμον ἐν πολέμφ, καὶ ἐράσμιον ἐν πολεήταις]
Γαίαν ἀβυρώβαι [πάσαις βαλίαιει κέλοντα].
```

Figure 6.73. This is the transcription of the Sphinx inscription into lowercase Greek such as is used by modern scholars, published in the *Quarterly Review* in 1819. This transcription and effort to fill in the gaps was done by a classicist named Dr. Young. The first two words in line four speak of the Sphinx as an "island of a rock."

It is necessary to point out that the reference to the Greek goddess Leto is merely a polite reference to the region in which the Sphinx lies. The name given to it in Greek by the Ptolemies was the Letopolitan Nome (a *nome* being an administrative district). The Sphinx is thus called a "servant of Leto" only because the Sphinx sits in the administrative district named after Leto. This is a flowery bit of "officialese," because it is a formal state occasion.

Here is the earlier translation by Dr. Young into rhyming verse, which was published 1819, where Leto is called by her Latin name of Latona:

Thy form stupendous here the gods have placed, Sparing each spot of harvest-bearing land; And with this mighty work of art have graced A rocky isle, encumber'd once with sand; And near the pyramids have bid thee stand:

Not that fierce Sphinx that Thebes erewhile laid waste,

But great Latona's servant mild and bland; Watching that prince beloved who fills the throne Of Egypt's plains, and calls the Nile his own. That heavenly monarch [who his foes defies], Like Vulcan powerful [and Pallas wise].

ARRIAN<sup>82</sup>

It is a pity that the bottom lines of the inscription were not preserved properly, although Arrian's signature at the bottom is perfectly clear (see figure 6.50 for the reproduction of the original inscription, where arrianos, the Greek form of Arrian, is written as arrianoc, because the final *s* tended to be written like that in inscriptions in those days). Dr. Young has not hesitated to fill in some missing bits in square brackets and otherwise, reading understandably *ouranon* where the initial *o* is lacking and only *–uranon* survives (hence the appearance of "heavenly" in his tenth line of verse), but he has not attempted to reconstruct the last two lines at all, even though fragments can be seen. He also omits the name of Oedipus. The last line appears to mention either gaia, "the Earth," or Gaia, the Earth goddess of the Greeks, but interpreting the orthography of ancient Greek inscriptions is a highly specialized skill that I lack entirely. The way the words run together and are not separated in these ancient texts is maddening and reminds me of the nightmare of my youthful days in dealing with this phenomenon as a student of Sanskrit (though in Sanskrit, the letters perversely "melt" and change into a new form when run together, as if designed to drive a student truly insane with frustration). However, on a have-a-go basis, I would say that I do not see the name of Thebes in the inscription following the mention of Oedipus in this inscription as published in 1819, or the mention of Osiris by name in the inscription either. However, the "island (made) of a rock" is very much there, at the beginning of line four, followed by psammon, the word for sand.

The Greek inscription was published again later, after some tidying up by a Reverend Coleridge of Eton, who was a classicist. This appeared in the appendix volume of *Operations Carried On at the Pyramids of Gizeh* by Colonel Howard Vyse and John Perring, London,  $1842.^{83}$  I reproduce this rather different version of the Greek inscription as figure 6.74. In this version, we can see that the name of Greek Thebes does indeed appear (as the last word of line six), whereas the word had been incorrectly transcribed in the version printed in 1819, with the *b* being written as a sigma, so Thebes could not be made out. In this version, the name of Osiris does also appear at the end of line eight (oceirin). Here is the translation done by Coleridge (who added "The Salutation of" in the last line himself):

The ever-living gods built thy . . . form,
Sparing the ground producing corn.
Having raised thee in the midst of the arable land,
Having driven back the sand from the rocky island;
A neighbour of the Pyramids they placed thee;
(A line seems wanting) . . . such to behold,
Not the slayer of Oedipus, as at Thebes,
But the goddess Latona, a most pure attendant,
protecting the regretted good Osiris
the revered governor of Egypt,

heavenly, great, like to Vulcan, the earth.

THE SALUTATION OF ARRIAN<sup>84</sup>

Figure 6.74. This is a second attempt to publish the inscription on the left paw of the Sphinx, an "improved version" prepared by the Reverend Coleridge of Eton. In this version, many of the words are clearer than in the version printed in 1819 and shown in figure 6.72. The name of Arrian, author of the verses, may be seen at the bottom (in Greek the letter that looks like a *P* is really an *R*). The name of Thebes is the last six letters of line six. The name of Osiris is the last seven letters of line eight. The first two words in line four speak of the Sphinx as an "island of a rock." This was published by Colonel Howard Vyse in 1842. Some of the inscription seems to have been lost since the excavation in 1817, possibly because the surface of the stone peeled, but other words are now clearer than in the previously published version.

If we examine what is said in this inscription, despite its incomplete state, we find that we are told (a) that the Sphinx is placed in a cavity, by which is meant the Sphinx Pit (although this does not come across in Coleridge's translation); (b) that the Sphinx is an island made of a rock; (c) that the sand has been driven back from the pit and from the Sphinx (held back by the retaining walls, which this inscription commemorates); (d) that the Sphinx is a neighbor of the pyramids; and (e) that the Sphinx stands guard over "the good, lamented," or "regretted good," Osiris.

What is important to us is that the Sphinx is described as an island made of a rock. The Greek adjective describing the island is *petraios*. This is a word that has the meaning "of a rock." It is not strictly accurate to translate it as "rocky," as if one were referring to lots of rocks, although the word was used that way sometimes. But there were other related words such as *petrinos* that were more commonly used to mean "rocky." This particular word was presumably chosen because it was recognized that the Sphinx was a *single* rock. And as this single rock was purposefully described in AD 166 on a state occasion by the scholarly historian Arrian as being "an island," I rest my case.

## THE SPHINX AND THE GIZA PLAN

The mysterious plan of the Plateau of Giza will be described later on in this chapter, and is illustrated in figure 7.25. It is one of the most fantastic survivals of ancient Egypt, in some ways more remarkable than the monuments themselves, since it actually embodies them within a larger scheme so complex and ingenious that it reminds me of a modern computer program run amok. And it is a plan not only in two dimensions, but in three as well. We shall see that the Sphinx and the Giza pyramids have a precise and direct relation with one another, a relation so specific that the monuments mutually determine one another's positions on the plateau. They form a unified complex. There are numerous correlations, and one may be seen in figure 7.2, which is a detail of the intriguing figure 7.1 and shows the Sphinx from the top of the Great Pyramid. If we look from that point, a line seems to cross the Sphinx's head and become a diagonal through the Valley Temple from its northwestern corner to its southeastern corner, perhaps touching the northwest corner of the Sphinx Temple in the process. I have chosen not to represent this in figure 7.25, which details what I call the Golden Giza Plan, because if this line is intentional and not fortuitous, it appears to represent a correlation that is additional to the "system" of the golden angles, which it is my main purpose to make clear to readers.

It is the Golden Giza Plan in figure 7.25 that proves the main Giza monuments were constructed to a unified plan. The size, position, and general shape of the Sphinx are determined by sighting lines (or "rays," as I like to call them) from the pyramids, which all are generated by the use of a single angle, the sacred angle on which the whole of ancient Egyptian art and sacred and royal architecture were based for religious reasons.

Figure 7.1. A stereoview photo from the top of the Great Pyramid, looking southeast toward the Sphinx, which is in the top right corner, unfortunately covered in shade from a passing cloud. See the detail of it in figure 7.2. In this photo, one gets an impression of the dizzying height of the pyramid, more than 500 feet up in the air with the birds. No place for a person with vertigo! This photo was probably taken in the late 1930s, as the excavated Sphinx Temple is at the feet of the Sphinx. The modern access road to the

Figure 7.2. This detail of the previous photo shows how the center of the head of the Sphinx is in line with the diagonal joining the northwest and southeast corners of the Valley Temple, as seen from the top of the Great Pyramid. (*Collection of Robert Temple*)

But before we come to that, we must consider some ancient Egyptian texts that seem to describe some of the mysteries and design of Giza. The ultimate answers to the mysteries of the geometrical plan of Giza are deeply connected with the most bizarre complex of mythological concepts dealing with death and resurrection. And at the most fundamental level, this all emanated from a single idea: the profound conviction that the universe was based on what the Egyptians called Maāt, or Cosmic Order. Most people think that the Egyptian religious beliefs were spread across many gods and were diffuse and unfocused as a result. It is true that they had many gods, but they had only one Cosmic Order. In that sense, they were more profoundly monotheist than any people since. Ultimately, what they really worshipped was One Principle, with their many gods arranged like so many flowers around its altar of perfection. However, we shall see what comes out of a closer examination of why anyone would construct anything quite so weird as the Giza necropolis; and for the first time for thousands of years, its geometrical plan will become as plain as it was to those who constructed it in the first place.

There are some very strange ancient texts indeed that we must now consider. These are of a different category than the Pyramid Texts from Saqqara that we examined in the chapter on the Sphinx as Anubis. These texts are preserved both in the form of papyri and as sacred Coffin Texts of the Middle Kingdom, and as wall texts in royal tombs of the New Kingdom. The texts were considered so special that they were supposed to be used only by the deceased kings, although a few nobles did so also. Although the wall texts are known only from the period of the New Kingdom, commencing with the Eighteenth Dynasty (circa 1540 BC), they are believed by Egyptologists to be very much older and to have been "recycled" in the New Kingdom. They are thought to date from the Old Kingdom, the Pyramid Age, circa 2700–2200 BC, when Giza was central to the concerns of all the priests and scribes of Egypt. By the time of the New Kingdom, when the capital of Egypt was at Thebes in the south (a town now called Luxor), Giza was no longer central to Egyptian civilization, pharaohs were not building their tombs there, and certainly they were not building any pyramids there. The pharaohs by that time were all being buried in the famous Valley of the Kings across the river from Thebes (Luxor). As we know from the inscription on the Dream Stela erected in front of the Sphinx by the New Kingdom pharaoh Thutmosis (Thothmes) IV, who excavated the Sphinx at Giza as a result of his dream, until then Giza had been a place where one went hunting on horseback and dozed in the shade afforded by the head of the Sphinx, as that and the top of the back were the only portions of that monument that still protruded from the sand. (I assume the top of the back was visible, for otherwise Thutmosis would not have known that the body was buried by sand, as there would have been no evidence of a body's existence.) Giza was essentially deserted. The New Kingdom pharaohs erected a few pathetic little temples there (less impressive, I must say, than many eighteenth-century English garden monuments and decorative mock temples in places such as Buckinghamshire) to show their reverence for the ancient sacred place, but otherwise Giza was of little concern to them (see figures 7.3 to 7.5). This changed to a certain extent after the Sphinx was cleared and it became the center of a minor cult, with an altar for offerings to the spirit of the Sphinx. No one remembered that it had once been Anubis. It was accepted at face value, as a monument with a pharaoh's face (no one would have remembered which one) and an animal body that from that time onward came to be thought of as a lion. In other words, people of the new Kingdom were as ignorant of the body being that of a dog as modern people are.

Figure 7.3. This interior doorway of the small New Kingdom Temple of Amenhotep II at the northeastern corner of the Sphinx Pit has been constructed in such a way that it is in perfect alignment with the Great Pyramid, whose apex is aligned with the center of the doorway and lintel. The view is toward the northwest. The wall beyond the temple, where some people are, is the foundation and border wall of the modern access road from Nazlet el-Samman to the pyramids. It was constructed some timeafter the Second World War. The siting of this temple in such an obvious way to align with the apex of the Great Pyramid reminds us of the relationship of the apex of the Pyramid of Chephren with the floor of the Sphinx Temple (that sight line is at the golden angle, as measured with an inclinometer), and also the general Giza Plan, as it specifies the precise size and location of the Sphinx with relation to the two main pyramids, as described in the text. (*Photo by Robert Temple*)

The New Kingdom pharaohs could not manage to build pyramids anymore through loss of the techniques and skills of their predecessors, and they put their efforts into temples and obelisks instead. The Pyramid Age had well and truly passed. Therefore, when pharaohs and nobles of that time used sacred texts referring to Giza and its lore, these were drawn from papyri that preserved the texts from an earlier era. Egyptian religious practice was always highly conservative, and texts were recycled over the centuries. This is true in modern Christianity as well. In church, people still say the Lord's Prayer, which was a prayer said to have been spoken by Jeschu (more commonly known by the Latin form of his name as Jesus) the Nazarene two thousand years ago. No one feels uncomfortable about this. Although new translations have been made, no one says: "This prayer is no good, it's too old, let's throw it out and get a new one." It retains its validity, its importance, and its relevance even in the twenty-first century. Of course, it has been expanded since the time of Jesus. It now says at the end: "For thine is the Kingdom, the power, and the glory, forever and ever, Amen." Jesus never said any of that. His original prayer ended with the words: ". . . and deliver us from evil." Clerics cannot resist tinkering and trying to improve things. Sometimes the Lord's Prayer is said without the extra bits, in its pure form, but there seems to be no pattern determining when it will be said in its pure form and when it will be said in its expanded form. Jews do not complain when rabbis read the Torah, which is hundreds of years older than the Lord's Prayer. Muslims do not complain when someone reads from the Koran, even though it was written in the seventh century. What Hindu has ever complained about his priests, the brahmins, reciting passages from their earliest sacred texts, the Vedas, which are 3,500 years old, even though they are in Sanskrit, a language that only a handful of scholars can any longer understand? (I studied Sanskrit at university, and I can assure you that it is one of the most difficult subjects of study you can possibly imagine, and no wonder no one can understand it anymore, as it has the most complicated grammar of any language in the history of the world. It was by far the most difficult thing I ever had to learn.) So it should not surprise us, therefore, based on what we know of modern religions, to discover that the New Kingdom Egyptians were also using texts that were many hundreds of years old, or even as much as 1,200 years old. After all, most of these texts were not nearly as old for them as the Lord's Prayer is for us now, and were less than half the age the Torah is today. But also, as with the Lord's Prayer, they could not resist tinkering sometimes, and adding some bits. People are always fidgeting, tinkering and fiddling with things if only out of nerves.

Figure 7.4. A photo, facing southwest, of the author standing in the doorway of the small New Kingdom Temple of Amenhotep II, overlooking the northeastern portion of the Sphinx. The center of the lintel of the doorway is aligned with the center of the Sphinx's forehead at the top of its head, which was one of the artistic canonical measuring points in traditional Egyptian art. (*Photo by Olivia Temple*)

Figure 7.5. This photo taken in 1951 by Selim Hassan shows the small New Kingdom Temple of Amenhotep II situated in front of the Sphinx, at an angle and to the left. The temple was excavated by Hassan in the mid-1930s. Since this photo was taken, the authorities have raised some of the fallen stones and reconstructed much of the structure, which was not particularly difficult to do, I suspect. This photo was reproduced very poorly in Hassan's book, *The Great Sphinx and Its Secrets*, Cairo, 1953, as figure 34 on page 47. However, I bought the original print from a dealer and have therefore been able to reproduce it at last with proper definition in a digital scan and by modern printing. (*Collection of Robert Temple*)

There are many surviving ancient Egyptian texts dealing with the afterlife and the netherworld, the best known being the so-called *Book of the Dead*. However, this name *Book of the Dead* is unfortunate, since it is not a real title. It is merely a survival of the name given to a variety of afterlife spells written on papyri that were found in coffins by grave robbers. When the robbers came across these writings, which of course they were unable to read, they merely referred to them collectively as "books of the dead," that is, books belonging to the dead men and women whose mummies they were robbing. The *Book* 

of the Dead was thus never a book, and there are many different collections of chapters and spells gathered together in different combinations that have come to be known under this general designation. Some portions of this material did have a kind of unity to them; for instance, the title of one genuinely ancient part of the material was *The Book of Coming Forth by Day*. (This refers to the resurrection of the dead.) But one should keep in mind that there is no actual Egyptian *Book of the Dead* as such. This is quite different from the situation in Tibet, where there is another work called *The Book of the Dead* (first committed to writing in the eighth century AD), which is a unified text about the experiences of the deceased soul, together with instructions to be shouted into the ear of the dead person to help him or her navigate the difficult realms of the afterlife. Needless to say, there is absolutely no direct connection of any kind between the Tibetan *Book of the Dead* and the Egyptian texts grouped under the misnomer *The Book of the Dead*. However, the title "Book of the Dead" is considered so evocative and is at the same time so simple and so easily grasped that many members of the public who know little more than the title are inclined to think they know what it is, which merely adds to the confusion. The title has the illusory sense of completeness of a well-edited television sound bite and can lead people astray just as easily.

There are some portions of the *Book of the Dead* material that appear to refer to Giza. But the most important texts about Giza are two sections of the earliest actual "book" of the underworld, which is now known as *The Book of the Am-Duat*, or *The Book of What Is in the Netherworld*. This was not its original title. In the text itself, its original title is given as *Book of the Hidden Chamber*.<sup>2</sup>

Since hidden chambers are an important theme for us, and the subject of an entire earlier chapter of this book, the title is certainly intriguing. I am inclined to view the *Book of the Am-Duat* as a work of the New Kingdom into which has been inserted a section, which is based on an ancient papyrus of the Old Kingdom that the later priests still possessed and decided to incorporate, although it didn't really fit. Many scholars have thought this, so it is not a new idea. There is a clear discontinuity in the text. For most of the *Book of the Am-Duat*, the sun is traveling across water in his boat at night through different gates and regions of the underworld, where he encounters a variety of gods and monsters. Each of the twelve regions of the underworld is called an "hour," and they are passed through in succession. However, the fourth and fifth hours are quite unlike the other hours, so much so that the sun god even has to leave his boat and travel across sand. It is at this point that he is in the realm of the hawk-headed god Sokar, also spelled Sokaris or Seker. And there seems to be agreement among the authorities that this refers to the necropolis of Giza.

I think *Book of the Hidden Chamber* is probably the original title of the earlier work that contained these two chapters, especially as the section of the fourth and fifth hours refers to hidden chambers. There are various depictions of hidden chambers in the ancient netherworld illustrations, and one of the best is from the left wall of Sarcophagus Hall I in the tomb of Rameses VI (see figure 7.7). The Hidden Chamber was generally inhabited by the deceased Osiris awaiting resurrection. Sometimes it was inhabited by the god of the resurrect-able aspects of the netherworld, Sokar, which may go back to the earlier tradition before Osiris became amalgamated with Sokar. (Sokar had no connection with the damned, who were given over to torture and eventual destruction in the Place of Annihilation, tasks that were the jobs of others.) I suspect that the title *Book of the Hidden Chamber* later came to be applied to the New Kingdom Am-Duat book as a whole, carried over from the earlier text of the two chapters that were preserved in something approaching their original form.

The weird contents of this section of the fourth and fifth hours must be studied with some attention, as certain clues seem to be found there that may assist us in considering the Giza Plateau. It should be noted also that a clear illustration of a pyramid is to be found in this section (see figures 7.6 and 7.7).

Wallis Budge as long ago as 1904 realized that the fourth and fifth hours were an insertion into the larger book and once consisted of a self-contained underworld of their own. In *The Gods of the Egyptians*, he wrote: "The domain of Seker [Budge always spells Sokar in the form Seker], although reduced to two hours which have been inserted in their proper geographical position in the [Underworld], certainly at one time formed a complete hell, and . . . the rising of the sun was the final event which took place in it." <sup>3</sup>

This domain of Sokar, identified with Giza, was also known as Rostau. But like all Egyptian names, Rostau can be spelled in various ways, as we have already seen earlier in this book. Budge spells it Restau. It was also occasionally called Restatet. Some Egyptologists prefer Rosetau and others use the form Ro-Setawe. This name, which we shall continue to spell Rostau, seems to refer specifically to the underground region at Giza. But it was also by extension sometimes the ancient name for the Giza Plateau as a whole (as separate from Djedu, later known in Greek as Busiris, which was the adjoining village to the east). The translated meaning of the name is Mouth of the Passages<sup>4</sup> or, in other words, Entrance to the Passages. And the passages meant are, obviously, the secret passages of the Giza Plateau, both those underground and, by extension, those concealed within the pyramids.

Figure 7.6. This carving of the god Sokar is found on a wall in the most mysterious and esoteric of all the underground crypts beneath the Temple of Denderah in Upper Egypt, where strange rituals or initiations are believed to have taken place. The crypt is known as Chamber C of the North Crypts. Sokar's name in hieroglyphics is in the small rectangle beside his head. See the drawing of this wall in figure 8.25. Sokar was often portrayed as a hawk or a mummified hawk (not to be confused with the god Horus, who was also portrayed as a hawk, but never mummified). Sokar presided over the world of the dead and was an entirely subterranean divinity who never came to the surface. The modern name of Saqqara derives from the name Sokar, because of its many subterranean passages and chambers and its proximity to Giza. Sokar's actual home was said to be at Rostau, or Rosetau, which was described as being at the foot of the Giza Plateau, at the same location as the Sphinx, just west of the village that in Greek times was called Busiris but is today called Nazlet el-Samman. It was there that Sokar had a temple of his own, believed to be what is today called the Valley Temple of Chephren, a huge, gloomy structure made of megalithic blocks of granite. Sokar was the Old Kingdom's underground god and was intimately associated with the dog Anubis, who was the surface guardian of the necropolis and of the dead. They were the predecessors of the later god Osiris, who from the time of the Fifth and Sixth Dynasties usurped both their functions and became the King of the Underworld. From then on, the humanized Sokar, under the name of Osiris, could be successively identified with every dead king, who after death was said to "become an Osiris." A mummiform version of Sokar carried in a sacred barque is shown in figure 7.22, an engraving from circa 1798 of a carving that is

now believed to have been lost or destroyed. In the Old Kingdom, there was an annual Festival of Sokar at Giza, when this image of Sokar sitting in a celestial boat was carried around by the priests as part of an itinerant celebration. (*Photo by Robert Temple*)

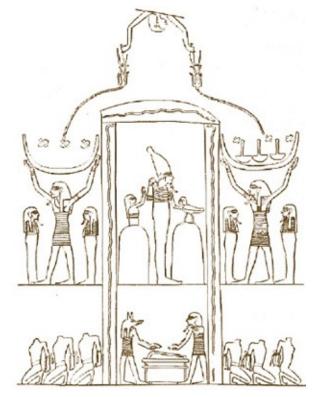

Figure 7.7. This evocative depiction of a hidden chamber in the netherworld shows a chamber with two stories. On the top story, Osiris is standing as a mummy, wearing the crown of Upper Egypt. In front of him, his own *ba* (spiritual force), called in the text "the Soul of Osiris in the West," is worshipping him and standing on a mound, while the Earth god Geb arises from a mound behind him, also in a posture of adoration. In the lower story, the god Anubis and another figure, probably the Earth god Geb, but called in the text "the One over the Mysteries," preside over a chest called in the text "the mysterious chest." This chest contains the secret of secrets, the thing most carefully guarded of all, and no one is allowed to know what it is. To the right and left of the bottom story are kneeling figures of the evil dead, their hands bound behind their backs in the posture of captives, who have been decapitated as the first stage of their annihilation. To the right and left of the hidden chamber are vertical Nehep serpents standing on their tails, signifying resurrection. The caldrons being held aloft on either side in the top register hold, on the left, hearts, and on the right, a mixture of hearts and upsidedown soul-shadows (all the dead were believed to enter the netherworld upside down). The hearts and soul-shadows are pouring from the streams of blood of upside-down decapitated corpses who are being lowered from the sky. (*From Alexandre Piankoff*, The Tomb of Rameses VI, *Pantheon Books*, *New York*, 1954, figure 110 on p. 357)

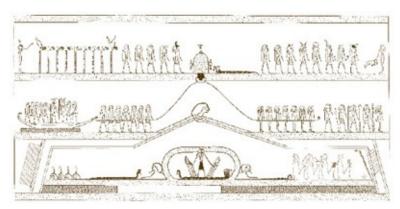

Figure 7.8. This section-view image of a pyramid is found in the fifth hour of *The Book of the Hidden Chamber*. Directly beneath it, the subterranean god Sokar with his falcon head is seen rising, opening a pair of wings, from the body of a serpent within an ellipse of sand. In the text he is called "the Great God who opens his two wings, He of the Dappled Plumage. . . . What he does is to guard his image." The text describes the sandy ellipse as "the mysterious cavern of Sokaris, He Who Is on His Sand." It is also known as the Cavern of the Hidden One. To either side of Sokar are the two heads of Aker, an underworld guardian deity. To the far right, a Nehep serpent leaps up above a star, indicating resurrection. The tip of the pyramid is a human head facing east, which is to the right in this picture. Above this head, the solar barge, known as Life of Power, is being towed across the sand by a rope that passes through the hands of Khepri, the beetle who assists the rising of the sun (see also the discussion of Khepri in the text). The text states: "The towrope which you have brought, the towrope is lifted by Khepri that he may help Re, that he may make straight the mysterious ways of Re, Horus of the Horizon." As the sun god passes the cavern of Sokar, the sun calls out to him: "Guard this thy image, O Sokaris, He who hides the mystery. I call thee, my words to thee are thy illumination, thou rejoicest hearing them." The substitution of a human head for the pyramidion tip of the pyramid is highly suggestive, indicating that the pyramids of Giza may have been conceived of as expectantly awaiting the rising sun to give his flash from their sheets of gold.

The head is also a hieroglyph, meaning *tep*, which not surprisingly has the basic meaning of "head," but also means "the top." The visual pun suggests that the top of a pyramid may have been known to the ancient Egyptians as its head. A photo of the same scene in the Tomb of Rameses VI is seen in figure 7.9. (*From Alexandre Piankoff*, The Tomb of Rameses VI, *Pantheon Books*, *New York*, 1954, *figure 78 on p. 261*)

I believe that there were also other "passages," laid out on "the sand of Sokar," namely the sand of the Giza Plateau itself, and that these were the invisible "rays" of the geometrical design shown in figure 7.25. However, our discussion of the rays and their significance comes later.

The Book of the Hidden Chamber (for that is how I intend to refer to it from now on, as this is its true ancient title) commences its description of Giza with a picture of a descending passage beside which stands the goddess Neith wearing the Crown of the North. (The crown, the goddess, and North all have the same name in Egyptian, *net*. Neith is the Greek form of the name used by scholars, just as they generally call Khafre by the Greek form of his name, Chephren, etc.) It seems reasonable to assume, therefore, that this picture refers symbolically to a northern entrance. Because the three main pyramids at Giza all have descending passages with northern entrances, and since the description is meant to be of Giza, it does not seem to be stretching a point to conclude that at least the commencement of the strange illustrations of "the passages of Rostau" in *The Book of the Hidden Chamber* begin with that simplest of things, the entrance to a major pyramid. Presumably the Great Pyramid was intended. It is most unlikely to be a coincidence that the entrance to Rostau is shown in the papyri and the wall paintings to be "northern," when it was the north faces of all the main pyramids at Giza that "led into Rostau."

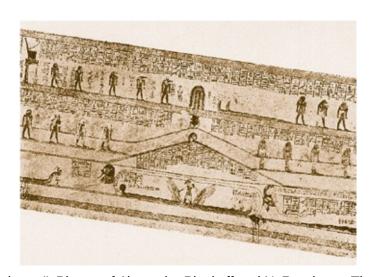

Figure 7.9. This is plate 86 from volume II: Plates, of Alexandre Piankoff and N. Rambova, *The Tomb of Ramesses VI*, Bollingen Series XL.1 (New York: Pantheon Books, 1954), photos by L. F. Husson. This image is from the left wall of Corridor G in the tomb and illustrates the fifth division of the ancient text called *The Book of What Is in the Netherworld*. The introductory text states: This Great God [the Sun] is towed along the right ways of the netherworld on the upper half of the mysterious Cavern of Sokaris.

He on His Sand, invisible and imperceptible—to make the mysterious arrangements in the land which carries this divine flesh. . . . The name of the Gate of this City is Stop of the Gods. The name of the Cavern of this god is the Hidden One. . . . It is done according to the plan which is drawn in the hidden region of the Netherworld in the South of the Hidden Chamber. He who knows it, his soul will be at peace, he will rest as Sokaris rests. (Translation by Piankoff in his volume I, p. 262)

In the center, a pyramidal mound is portrayed, topped by a head, above which the scarab beetle is rising, symbolizing the rising sun. Beneath the pyramid, in his subterranean elliptical chamber called the Hidden One, the god of the dead, Sokaris, rises, with his wings of resurrection expanding to either side of him. His cavern is guarded on either side by Aker, the double-headed protector deity of the netherworld, with face and paws facing each way. The text says of the mound that it is the "Flesh of Sokaris, He on His Sand" and then adds: "The image is like this in thick darkness. The egg which belongs to this god is lighted up by the eyes in the heads of this Great God [Aker], his flesh shines, the legs are inside in coils. The Great God keeps guard over this image. The noise is heard in the egg, after the Great God has passed by it, like the sound of roaring in the sky during a storm" (p. 267, Piankoff). In the middle register, various gods are towing the rope of the solar barque, dragging it across the sands of Giza, for that is the location of the secret chamber of Sokaris, which was said to be beside the Sphinx at Rostau. (*Photo copyright* © 1954 by the Bollingen Foundation)

Figure 8.6 is a photo I took of this entrance scene as it was painted on the walls of the Tomb of Rameses III in the Valley of the Kings. I don't believe the Rameses III version has ever been reproduced before, and it does not appear in any of the relevant books. Nor does Erik Hornung in his survey of Egyptian netherworld literature mention more than in passing the existence of a Rameses III version of *The Book of the Hidden Chamber*. This Rameses III version is a particularly vivid painting, as you can see.

Once we get past the entrance, however, things start to go awry with the tomb paintings and the papyri, and we quickly realize that however many interesting and even authentic details may be shown or hinted at in these pictures of the passages of Rostau, we do not by any means have a map or a straightforward plot of the existing structures and passages. Some curious features can be interpreted as accurate, still others are merely suggestive. But there is no attempt whatsoever to present a physically reliable depiction. It is doubtful if, by the time of the New Kingdom, anyone had the faintest idea of what really lay beneath the Giza Plateau or within the major pyramids. And it is not improbable that the ancient text, when it was reprocessed for inclusion in the New Kingdom text, had many of its truly ancient details removed by the unsuspecting adapters, and that tinkerings and adjustments were made to fit the passages of sandy Rostau into the underworld journey of the sun god, which otherwise took place over water.

A Netherworld Text that is Middle Kingdom in date, *The Book of the Two Ways*, also preserves some interesting information about Rostau, which it mentions frequently. This text is preserved only as paintings inside a few Eleventh and Twelfth Dynasty wooden coffins excavated at a single site, El-Bersheh in Middle Egypt. If these graves had not been found and the coffins excavated, we would not have the text at all. A complete translation was done by Alexandre Piankoff and published in 1974. Piankoff prefers the spelling Rosetau, which is therefore how the name appears in the quotations that I take from his translation.

The pictures painted in the coffins depicting Rostau are very crude compared to those illustrating *The Book of the Hidden Chamber*. But both agree in having the journey into the netherworld commence with a simple descending passage. In the case of *The Book of the Two Ways*, however, there is no goddess with the Crown of the North or any other indication of a cardinal point. The figure awaiting the unwary person entering the passage is a strange human-headed beast with no legs and a single arm holding a very large and threatening knife. The hieroglyphics state that the name of this creature is Voice-of-Misery, and he is the guardian of the entrance, which is known as the Gate of Darkness. As for the entrance passageway itself, we are told of it: "This way [leads] to the cities of Those-WhoLive-on-the Baboons (?) [the baboon was the symbol of the god Thoth, but baboons were also guardians of the netherworld's Lake of Fire and are frequently depicted sitting around it in illustrations accompanying *Book of the Dead* texts] . . the cities of the Roaring Knives. This is its way from below. Do not go by it."<sup>7</sup>

In front of the entrance to Rostau is the text that says:

I have passed by the roads of Rosetau by water and on land; these roads are those of Osiris; they are in the sky. If a man knows the Spell for going down into them, he will be like a god directed by the followers of Thoth. He will indeed go down to every heaven to which he desires to descend. But if he knows not this Spell for passing on these roads, he will fall a prey to the tribunal of the dead, his destiny being that of one who has nothing, and is without (his) justification eternally.<sup>8</sup>

Although the surface of Giza is now as dry as a bone, in the times of the Egyptian Old Kingdom and possibly the Middle Kingdom as well (until perhaps as late as 2200 or even 2000 BC), a harbor lapped

against the eastern walls of the Sphinx Temple and the Valley Temple, as I have already explained at length. It is doubtful that this harbor contained water all year long, but it certainly did during the period of the inundation of the Nile. And as I have already explained in detail, I believe that the Sphinx during these times sat in a deep moat of water that was fed from the adjoining harbor. After the water of the inundation receded, the water was trapped in the Sphinx Moat by the sluices, although as the months wore on, it would have become increasingly stagnant and lower in level from evaporation in the heat, hence the need for the previously mentioned drain to bring water from any rain that might occur down into the moat. During the New Kingdom, the pharaohs of that period landscaped and adapted the area for their small and unimpressive temples. There is still to this day a great deal of water underneath the Giza Plateau, as I have seen with my own eyes and photographed in the so-called Tomb of Osiris in the deep shaft beneath the Chephren Causeway, a site that I have studied in great detail, and my report concerning which can be found in *Egyptian Dawn*. In that book, my photo shows the miniature Osiris Island surrounded by a channel of water, with a sarcophagus in the middle (symbolic of a "tomb of Osiris"), more than 150 feet below the surface, which is reached by a succession of three shafts. Figure 7.10 shows the canal and water in the bottom level of the Osiris shaft.

Figure 7.10. This is a photo I took at the bottom of the Osiris Shaft at Giza, approximately 150 feet below the surface, in the third level. The shaft is entered beneath the Chephren Causeway. The central portion of the third level is an "Osiris Island" containing a sarcophagus. It is surrounded by this canal cut out of the bedrock and filled with water. This particular section of the canal is west of the central island. The southern wall of the chamber is at the rear of the photo. The water is covered with an opaque scum but is clear underneath if that is brushed aside. The Osiris Island at the bottom of this shaft portrays the same mythological setting as does the Osireion at Abydos in Upper Egypt. Speculations that this island and canal are of Saite date are false, and the true date is much earlier. (Photo by Robert Temple)

There is even water inside the Great Pyramid, for the "grotto" of the "well shaft" in that structure seems to be continually wet, even though there is strangely no water to be found at much lower levels, and not a drop is to be found within the Subterranean Chamber, the lowest point of all. We should keep all these things in mind when we read the ancient texts such as the above about the "roads by water and on land" at Rostau/Giza. Despite the desert and sandy conditions of Giza, water was always near at hand.

There is a curious part of the coffin pictures (see figure 7.11) showing four successive levels of what

appear to be angled stone slabs blocking the way. The accompanying hieroglyphic text appropriately says of them: "Flame. Spell concerning the roads of Rosetau. These ways lead astray in this manner: each one among them meets the next and leads astray. He who knows it will find their roads. They have high walls of flint in Rosetau upon water and upon land."

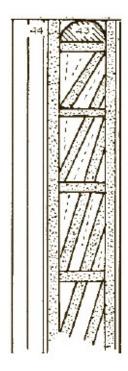

Figure 7.11. This is a detail of a drawing of the illustrated text of *The Book of Two Ways*, preserved on the lid of a coffin of Middle Kingdom date numbered CGC 28083 in the Egyptian Museum at Cairo. The large foldout drawing from which this small detail is taken is at the back of the volume *The Wandering of the Soul: Egyptian Religious Texts and Representations*, vol. 6, by Alexandre Piankoff and Helen Jacquet-Gordon, Bollingen Series XL:6 (Princeton, N.J.: Princeton University Press, 1974). The numbers 43 and 44 appearing at the top of the drawing were added by the modern artist to refer to the Coffin Texts relating to those places (Spells 1072 and 1073, respectively). These texts refer to the "high walls of flint in Rosetau" and "the Kneeling Ones with mysterious faces," which I believe refer to movable slabs that block passages. I believe these slabs may be pictorially represented here, on four successive tunnel levels.

"Flint" must be a mineralogical mistranslation, though the original Egyptian word is not given and it is not possible for me to give an alternative stone on the basis of what is published; however, Egyptologists are always getting their stones and minerals wrong, as I have many times discovered, working as I have done with stones and minerals in Egypt as part of our official researches there. There are three Egyptian words thought to mean flint, *ār*, *beshu*, and *desh*, but which is the word used in the text I do not know. Probably it was the mysterious word desh, which was specifically said to be black, was connected with magic, and was a "stuff of a decan," meaning a material associated with a division of the sky and the stars of that division. I find it difficult to believe that the real meaning of desh is "flint." But then, who am I, a mere mortal, to challenge the all-wise in such matters? Turning to the expert J. R. Harris for enlightenment, I find that all the experts are in confusion where references to "flint" are concerned, and especially regarding the confusing uses of the Egyptian word desh. According to Harris, "The textual evidence for desh is not very significant, and there are no definite indications of the meaning of the word." The famous Egyptologist Heinrich Brugsch at first throught desh meant "flint" and then changed his mind and thought it probably referred instead to limestone or alabaster. 10 That is certainly more appropriate for the "high walls" in Rosetau, although it would mean that they were white rather than black. At the very least, we may be confident that the translation of "flint" for the walls in Rosetau is incorrect, and that some form of stone is referred to.

And immediately adjoining these angled slabs, as may also be seen in figure 7.11, there is an adjoining vertical shaft of which we are told: "The Weary Ones, Kneeling Ones with mysterious faces, who live with the help of their throwing sticks. I am the stout of heart, he whose might is weighty, he who makes his way through the fire. . . . A way is made for me so that I may pass and save Osiris. I am he who sees the unique, who circles about, . . . he for whom a way is made, to whom it is granted to pass. In peace, in peace." 11

Because there are no figures of men, gods, or animals to be seen in this last section, the "Kneeling Ones with mysterious faces" appear not to be creatures at all, but stones of passages. I believe that these two sections of the picture and their texts refer to concealed entrances to passages such as the famous one inside the Great Pyramid at the junction between the Ascending and Descending Passages. In classical antiquity, the Descending Passage was known, but the roof of this passage contained a slab of limestone that concealed underneath a granite plug, the limestone being mounted on swivel bearings (see figure 7.15), which was flush to the roof but which, if moved or levered in the correct manner, could have been opened to reveal the Ascending Passage. This limestone slab fell off in the ninth century and has now been removed. I discuss this matter and quote a passage from the ancient Greek geographer Strabo about such stones later in this chapter. Even if this swivel stone was known, which is doubtful, the Ascending Passage could not be entered because it was blocked with the three granite plug stones (see figures 7.12 and 7.13). The swivel stone was an angled stone, like the ones in the coffin paintings, and I believe that the expression the "Kneeling Ones" is a general term that refers to such angled stones inside the pyramids. They are in the position of someone kneeling, and also, just like someone kneeling who rises to an erect position, they can be moved to become straight. They do indeed have "mysterious faces," because they are concealed and appear to be normal passage-lining stones. As for "liv[ing] with the help of their throwing sticks," this may be an esoteric allusion to their moving back and forth and returning to their place, just as the ancient Egyptian boomerangs did when used for hunting geese in flight. (Boomerangs are depicted in Old Kingdom tomb paintings, which show them being used in bird-hunting scenes.) "He whose might is weighty" could refer to the huge weight of these concealed and "kneeling" stone slabs that blocked the secret passage entrances. "Circles about" should probably be slightly retranslated to mean "turns about," referring to the movement of the swivel stone on its hinge. And "sees the Unique" may refer to seeing the hidden signs in the passageways that indicate the locations of the blocked passages, just as the intuitive genius Sir William Flinders Petrie discovered the markings in the Descending Passage that indicated the existence of the swivel stone of the Great Pyramid. And I have seen such signs myself, which I believe indicate a similar concealed passage that could be reached from the passage that leads to the Queen's Chamber. I discovered these one night when I had the interior of the Great Pyramid all to myself and was able to spend several hours minutely examining it inside without anyone disturbing me. During official opening hours, the crush of tourists is intolerable, and you cannot study anything properly at all.

Figure 7.12. This photo shows very clearly the granite plug (top of photo) blocking the entrance to the Ascending Passage of the Great Pyramid from the Descending Passage. The plug is still there because entry to the Ascending Passage is from the forced passage made by al-Mamoun, which was tunneled through the limestone and went around it. This is plate LXVII on page 171 of John and Morton Edgar's *The Great Pyramid Passages and Chambers*, volume 1, Glasgow, 1910.

Figure 7.13. A photo of John Edgar, the pyramidologist, suspending a plumb bob at the point in the Descending Passage inside the Great Pyramid at Giza where the lowest of three successive granite plug stones may be seen in the roof, blocking access to the Ascending Passage. The limestone swivel stone that once concealed this granite plug stone from view had already been removed by this time (circa 1909). Edgar's own caption gives further details. This is plate LXVIII on page 172 of John Edgar and Morton Edgar, *The Great Pyramid Passages and Chambers*, volume 1, Glasgow, 1910 (the original edition with the best-quality plates). John Edgar died as this book was in press in 1910. His measurements, studies, and above all his unrivaled interior photos (all of which would be impossible today) are extremely valuable. He spared no trouble and expense in obtaining the very finest photography possible at that time for interior views of every passage and chamber of the Great Pyramid.

In this esoteric manner that I have just suggested, genuine physical details of pyramid construction

seem to be hinted at. But they appear to be general and not confined to a single edifice such as the Great Pyramid alone, assuming that such blocked passages exist in most or all of the main pyramids. Since an empty concealed passage was discovered in the Pyramid of Meidum as recently as 1999, announced in 2000, and published in 2003,<sup>12</sup> and an analogous concealed passage above the passage leading to the Queen's Chamber in the Great Pyramid almost certainly exists, as many Egyptologists have now concluded, it seems likely that such passages are common, whether they are merely "relieving passages" connected with structural concerns or are genuinely intended to lead somewhere of interest or to contain something of importance.

Another statement in *The Book of Two Ways* that seems reasonably accurate in reference to these phenomena is the statement quoted above about how the roads of Rostau lead astray: "Each one among them meets the next and leads astray." This is an accurate description of what happens inside the Great Pyramid, since the Descending Passage meets the once concealed and blocked entrance to the Ascending Passage but continues to descend and thus "leads astray."

Yet another feature is of interest in the coffin painting from which the detail of figure 7.11 is taken. To the right of the stone slabs we see three horizontal passages directly over one another and separated from each other by stone courses. The text says: "Spell to pass over him [and] those who are below him." 13

Now that the two horizontal passages with one directly over the other have been discovered inside the Pyramid of Meidum, and bearing in mind the suggested second passage lying directly over the passage leading to the Queen's Chamber inside the Great Pyramid, with of course the Grand Gallery in turn lying over that, we can appreciate that this picture may be an allusion to the structures inside at least two major pyramids. Indeed, it seems that three passages lying above one another do actually exist inside the Great Pyramid, as just described, and if one counts the Descending Passage, three are already known anyway.

Further on in the picture, two horizontal passages are shown lying one above the other. The text above them says: "The roads of Rosetau upon land." And beneath them the text says:

I have come to establish the things at Abydos, I have opened Rosetau, I have alleviated the suffering of Osiris. I am he . . . who makes his way in the valley. Oh Great One, make a path of light for me, that I may pass. . . . As to these Kneeling Ones, Geb [the primeval god of the Earth] has placed them in Rosetau near his son Osiris out of fear of his brother Seth, lest he might hurt him (?). If any man knows the names of these Kneeling Ones, he will be with Osiris forever, he will never perish. 14

Figure 7.14. The strange Pyramid of Meidum, four hours' drive south of Cairo, which may or may not have partially collapsed in

antiquity (not everyone is in agreement as to what really happened to this structure, which is still surrounded by huge mounds of stone and rubble, as seen here). Did someone try to build a pyramid at too steep an angle, causing a disastrous failure in the structure? Inside it a concealed passage was discovered as recently as 1999. It could not be entered but was explored by means of fiber-optic probes. It is parallel to a known passage, and it is believed that a similar concealed parallel passage exists inside the Great Pyramid, running above the familiar passage that leads to the so-called Queen's Chamber. Such passages may be merely what engineers call "relieving passages" for construction purposes, or they may have a different purpose. Alas, too many of the interior features of the pyramids are baffling, and there may well be numerous undiscovered spaces inside them that we have not yet found or may even never find. (*Photo by Robert Temple*)

My suggestion that "the Kneeling Ones" are really angled swivel stones concealing entrances (such as the one known originally to have concealed the entrance to the Great Pyramid itself, seen in figure 7.15) draws support from a further portion of the text, which says: "If any man is seen there alive [in the innermost sanctum of Rostau], he will not perish eternally since he knows the Spell for passing the Kneeling Ones, the keepers of the gates." <sup>15</sup>

This makes it very clear that "the Kneeling Ones" are obstacles sealing the "gates" of the Rostau passages.

Not a great deal is known of the mechanical techniques by which the huge slabs were actually moved on their hinges in the ancient monuments, since although we can see the hinges and we know that such stones existed—and indeed the one at the entrance to the Great Pyramid is even described in the Greek text of Strabo (quoted in a moment) as still being in use and swinging open in Roman times—none survives intact. The one drawn by Flinders Petrie at the Bent Pyramid of Dashur no longer exists either (see figure 7.15, left side of picture). That pyramid at Dashur is extremely unsafe to approach and explore, due to the fact that it has so many of its original casing stones, and they sometimes fall off! For decades it was inaccessible because it was in a closed military zone, and obviously it was not studied during that time. The last time it was studied properly was by the brilliant Egyptian archaeologist Ahmed Fakhry in the days before Nasser came to power and created more military zones. I am very fortunate indeed to have a copy of his extremely rare work in three volumes, *The Monuments of Sneferu at Dashur*, the first volume of which deals entirely with the Bent Pyramid (volume I, Cairo, 1959). There is no mention or depiction of the swivel door in Fakhry's book, and I presume that Flinders Petrie's drawing was entirely a reconstruction.

There must be some swivel doors that are still in place and serving their purpose, but we have simply not discovered them because they are serving their purpose too well and remain successfully disguised! But whether one pushes on a certain spot in a certain manner or perhaps uses some lever or implement (perhaps referred to in the reference to "throwing sticks"?) to make a block of many tons' weight suddenly move on its hinges and open, we do not know. For most of her life at Abydos, Omm Sety, Selim Hassan's assistant, was always going around the Temple of Seti I and pushing here and there on suspicious-looking slabs, hoping to open them and gain entry to the many passages and chambers and crypts that she was certain were concealed both in and under the Temple of Seti I and in the Osireion and the tunnel she believed linked the two, but she never succeeded in finding the right way to shift any of these slabs. Who knows? Perhaps they don't work after all these millennia. Maybe they have become stiff and have "slab arthritis."

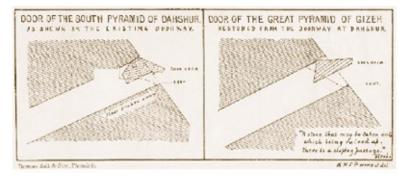

Figure 7.15. These two diagrams were published by Sir William Flinders Petrie as part of plate 11 of the first (and fuller) edition of his book *The Pyramids and Temples of Gizeh*, London, 1883. The diagram on the left shows the swiveling-stone trick door that once led to the passage inside the Bent Pyramid at Dashur, but no longer exists in that pyramid, which retains many of its original casing stones. The diagram on the right shows Petrie's reconstruction of the similar trick swivel door that would originally have led into the Descending Passage of the Great Pyramid, and which was still in use in the first century AD, as recorded by the geographer Strabo. I believe that these secret swivel doors of stone that traditionally concealed the entrances to passages were the "Kneeling Ones" referred to in the Egyptian netherworld texts.

The one famous exception to this, of course, is the swivel slab that she seems to have opened by accident one day when she was stumbling around the temple and in a high fever because she was afflicted with Asian flu, feeling very dizzy and ill, and unexpectedly fell into a treasure room. She recounts this incident in her book. Let During 1999, an intensive search for this chamber was carried on at the temple in Abydos by an American researcher. Although he did not find the chamber, in 1998 the remnants of a passage inside a wall near the Hall of Barques was found by the Egyptian archaeologist Ahmed El-Sawy, although it contained nothing of interest and does not appear to have been a passage of any major importance; this discovery was announced at the Eighth International Congress of Egyptologists, which I attended in Cairo in the spring of 2000, and was published in 2003. Let Let Sawy's careful and conscientious work at Abydos was of the greatest possible interest to those who are interested in the Temple of Seti I at Abydos, a structure in which I have already written a detailed report of more than 60,000 words about our work there, which has not yet been published, and which will reveal many unexpected things when it appears. This does not appear in *Egyptian Dawn* because that book does not discuss the New Kingdom period.

If we can begin to decode the esoteric references in some of the ancient texts, we are in a better position to retrieve possibly important information about the monuments. By recognizing that the "Kneeling Ones" are probably swivel slabs blocking passageways, we are already getting somewhere.

The only contemporary description of a "Kneeling One" actually in use is found in the *Geography* of Strabo, a Greek writer who lived during the Roman Empire, first century BC–first century AD. Strabo visited Egypt, and in Book 17 of his lengthy work, he describes visiting the pyramids of Giza. He writes, "At the distance of 40 stadia from Memphis is a brow of a hill, on which are many pyramids, the tombs of the kings. Three of them are considerable. Two of these are reckoned among the seven wonders [of the world]. . . . One pyramid is a little larger than the other. At a moderate height in one of the sides is a stone, which may be taken out; when that is removed, there is an oblique passage [leading] to the tomb." 18

This proves that in Roman times the Descending Passage and the Subterranean Chamber (thought by the Romans to have been "the tomb," though no one today believes that) were known and regularly entered by tourists, and also clearly indicates that the Ascending Passage, Grand Gallery, and chambers higher up inside the Great Pyramid were entirely unknown at that time, since there is no mention of them at all. The swivel stone that could be "taken out" so that one could enter the Great Pyramid from the northern face is seen in reconstruction in figure 7.15. Figure 7.16 is a nineteenth-century photo of this

original entrance where the swivel stone once was; figure 7.17 shows its appearance in 1610. Strabo does not say how one got up the slippery side to this point, but there must have been a stairway or steps made for the visitors. At this time, of course, the casing stones still covered the pyramids, and Strabo even describes those covering the small Pyramid of Mycerinus (Menkaure) as being made of dark granite, but only "nearly as far as the middle," the upper half of that pyramid apparently having been covered with the normal limestone. <sup>19</sup> It is interesting to know that the movable entrance stone of the Great Pyramid still functioned on a regular, presumably daily basis in the first century AD.

There are various scattered references in Greek literature to doors strangely swinging open in temples. In the *Ecclesiastical History* of Sozomen (fifth century AD), we find mention of a curious case of prison doors that "though fastened, opened of their own accord."<sup>20</sup> The inventor Hero of Alexandria (who lived in the first and second centuries AD) in his book *Pneumatics* actually describes a mechanical device that can cause the doors of temples to swing open automatically and is triggered when somebody sacrifices upon an altar.<sup>21</sup> So mysteriously opening doors have been a feature of important sacred structures throughout antiquity.

There is one other possible esoteric reference that could be implied by the expression the "Kneeling Ones." The sides of an acute angle look like kneeling legs. Perhaps the golden angle is being hinted at. To "know the Kneeling Ones" at Giza could also mean working out a knowledge of the Golden Giza Plan, as shown in figure 7.25. And the phrase in the text above about making "a passage of light" might refer to one of the aerial "rays" at a golden angle, which I discuss later, particularly the one that strikes the tip of the Pyramid of Chephren from the Sphinx at sunrise on the equinox.

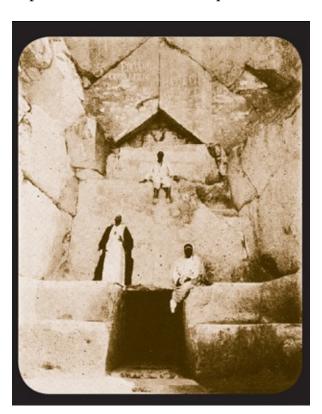

Figure 7.16. The original entrance to the Great Pyramid, which is on the north face. The casing stones originally covered this, and in Roman times the entry was by a casing stone that was a secret, movable swivel stone, which opened and let people in at this point. Roman tourists loved to enter the Descending Passage by this route and descend all the way to the Subterranean Chamber. The Ascending Passage was unknown to them, and hence also the Grand Gallery and the King's and Queen's Chambers. This old photo was reproduced only in a rare book entitled *Souvenir of Egypt*, published by George Dovas in Cairo (no date). It was given in 1898 to my grandmother by her friend Ebtenago Sehyoun, a Copt, of Kena in Egypt. She was friendly with him and some others of the Copts and had a particular interest in their culture and traditions. Directly above the head of the man sitting in the center of the photo is a strange shape carved in the stone, which Walter Marsham Adams in 1898 clamed was the hieroglyph for "horizon," showing two hills to either side with a dip in the middle, where the rising sun was meant to appear.

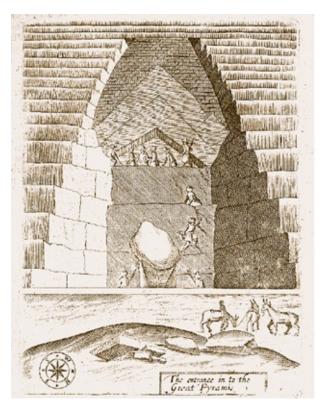

Figure 7.17. This engraving appeared in a book by George Sandys, A Relation of a Journey Begun An. Dom. 1610, London, 1615. It shows the original entrance to the Great Pyramid as it appeared at that time. (*Collection of Robert Temple*)

We must return now to *The Book of Two Ways*. Where things begin to get really interesting is in the descriptions of what is called "the Mystery of Rostau." There are various references to what appears to be the Great Hall or Chamber underground. Here are the suggestive passages:

Sealed is that thing which is in darkness. A flame is around it; it contains this efflux of Osiris, placed in Rosetau (?). He is hidden since he fell down into it. The descent to him goes over the country of sand. Indeed, what is under him is consecrated in Rosetau. . . . If any man is seen there alive, he will not perish eternally since he knows the Spell for passing the Kneeling Ones, the keepers of the gates. . . . Spell to be in Rosetau. I am the great Name, he who creates his light. I have come to thee, Osiris, I worship thee. He (the deceased) causes thy efflux to permit him to arise. . . . Spell to be in Rosetau, to live on the extra offerings beside Osiris. To proceed in peace; to protect Osiris; to pass by the gates. I am the great Name who creates his light. I have come to thee Osiris. I worship thee. Give me now away, I am purified by thy efflux. I have acted [so that I am the one] who has been exalted by the efflux which flowed out of thee. I have made the name of Rosetau since I fell into it. Salutation to thee, Osiris. Arise! Thou art powerful, thou art strong in life, health and prosperity, thou art powerful in Rosetau, thou art the strong one in Abydos. . . . O this charcoal wall!<sup>22</sup> I open my way in Rosetau that I may ease the suffering of Osiris. . . . [I am] he who is allowed to pass by. . . . These are the words of what is inside the [region] of darkness. If any spirit knows this, he will live among the living. A fire is around it which contains this efflux of Osiris. If any man knows this, he will not perish there forever, for he knows that which is in Rosetau, [namely] the Mystery of Rosetau, since he fell there. He who comes down to [this] desert which contains this chest [illustrated in figure 57] is he who carries it in Busiris. [The reference is to the small settlement of Busiris at the foot of the Sphinx of Giza itself, called by the Egyptians Djedu, now known as Nazlet el-Samman, the Greek name of which is recorded by Pliny, who says: "Close by (Memphis) is a village called Busiris,

where there are people who are used to climbing these pyramids."<sup>23</sup>] It is the decomposition of Osiris of Rosetau. . . . Grant that I may be brought to thee, O Thoth. I open the Netherworld. . . . The way of Thoth to the House of Truth. . . . I am Thoth, the Lord of Offerings for Osiris, . . . this is for my father Osiris who is on the High Ground. . . . I am the Great Soul of Osiris with whom the gods have ordained him to copulate, who lives on high by day, made by Osiris from the efflux of his flesh, [made] by the seed which came from his phallus, in order to come forth by day that he may copulate with it. . . . For I am the Great Soul of Osiris with whom the gods ordained him to copulate. He lives through it (the soul) on high by day, [the soul] made by Osiris from his efflux which is in his flesh, [made] with his semen which comes out of his phallus, in order to come forth by day that he may copulate with it.<sup>24</sup>

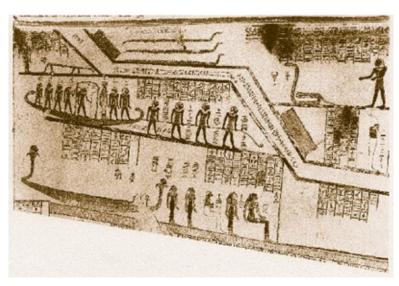

Figure 7.18. This is plate 80 from volume II: Plates, of Alexandre Piankoff and N. Rambova, *The Tomb of Ramesses VI*, Bollingen Series XL.1 (New York: Pantheon Books, 1954), photos by L. F. Husson. This image is from the left wall of Corridor G in the tomb and illustrates the fourth division of the ancient text called *The Book of What Is in the Netherworld*. The sun god, with a ram's head, is being towed in his solar barque. The text says: "The towing of this Great God is stopped for a while in this mysterious Cavern of the West whose forms are holy. Taking care of those who are in it with his voice without being seen by them. The name of the Cavern is Life of Forms. . . . The mysterious ways of Ro-setau [Rostau], the sacred roads of the Imhat Necropolis, the hidden gates which are in the earth of Sokaris, He on His Sand. . . . They are like this, the guardians of the Holy Way to the entrance of the West of the netherworld. It is they who keep guard on Anubis . . . Ro-Setau. The mysterious roads of Ro-Setau, the divine portals. He [the sun] does not pass by them, it is only his voice that they hear. The road to enter the body of Sokaris, He on His Sand, a mysterious image invisible and imperceptible. Mysterious road which Anubis enters (leading) to him who hides the body of Osiris" (translation of Piankoff, vol. I, pp. 254–60). (*Photo copyright* © 1954 by the Bollingen Foundation)

To judge from these strange remarks, the ultimate secret of Giza sounds like a chamber full of the semen of Osiris! (The world's oldest sperm bank?) Or perhaps the semen is contained in a chest in that chamber. One wonders whether this might perhaps even be a reference to the coffer of the King's Chamber in the Great Pyramid. It is possible that the reference in the text quoted above to "the High Ground" is to the Giza Plateau, which is indeed high ground above Memphis. But it is not only the semen of Osiris that appears to be hidden at Giza; it is also the "efflux" or "decomposition" of Osiris that is meant to be concealed there. And there are other references in the ancient texts to this efflux of decomposition of Osiris and its concealment. What could this mean? We should keep in mind that there is an analogy to this concept in Christianity. "The body and blood of Christ" are continually spoken of in a sacramental and evocative context, and often the blood becomes "the water and the blood," or the mixture of two fluids. In the Anglican/Episcopal Church, one of the hymns frequently sung by the congregation contains a line about "the water and the blood which from thee forever flow." I used to ask what this meant when I was a boy, and I met with puzzled reactions. One suggestion was that because the priests

mix water with the wine for communion purposes, *those* were "the water and the blood," as it is well known that the wine represents the blood of Christ, and devout people believe that through a magical and divine process that takes place during the mass, the wine is literally transformed into the blood of Christ, and that people who drink it really do drink Christ's blood itself, not just a substitute. This is what is called "taking communion." To suggest that priests add water to the wine because they don't want to become drunk at mass is not a satisfactory explanation for the words of the hymn and the theological concept behind them. There is no doubt whatsoever that there was some vague concept of "the water and the blood" both streaming as an efflux from Christ on the cross, as a result of the spear wounding him in his side, the "water" presumably being the bodily fluid known as lymph. I mention these strange, obscure, and somewhat necrophilic Christian theological details only because they offer such a tantalizing analogy to the "efflux" of Osiris, who also died and rose again "in sure and certain hope of resurrection," as the Christians say.

Figure 7.19. "O thou charcoal wall!" This quotation from the ancient Egyptian netherworld text *The Book of Two Ways*, which describes the obstacles and secrets concealed at Rosetau, may refer to the unexpected inclusion of a charcoal-colored basalt block in the midst of red granite blocks, such as this one at the Valley Temple of Giza, which is the traditional site of Rosetau. Not only does such a basalt block resemble a charcoal wall, but it was probably intended as a sign or signal to the initiated regarding the location of something. Since the text refers to a charcoal wall in connection with discussion of the "Kneeling Ones," which I have already explained as swivel stones that block concealed passages (see figure 7.15), a stone such as this might have acted either as a swivel stone or as an indicator of a swivel stone, or of some other concealed secret, behind or beneath. To find things that the Old Kingdom Egyptians concealed, you have to think like an Old Kingdom Egyptian; it is useless to insist on thinking like a modern person. This is why only a few modern archaeologists, such as Sir William Flinders Petrie, have ever been able to find what the ancient Egyptians had hidden. The subterranean temple, the Osireion, at Abydos, was discovered only because Petrie noticed a slight dip in the sand and his intuition told him to dig there. An Egyptologist who does not have a highly developed intuitive sense, or does not listen to it, will never be a discoverer. (*Photo by Robert Temple*)

The Egyptian word that is generally translated as "efflux" is *redju*. Technically, it is the fluid of decomposition oozing from the corpse. (In the extreme heat of Egypt, this would have occurred rapidly.) It was similar to but distinct from what the Egyptians called *fedet*, which is the sweat of the corpse, since *redju* comes from the interior of the corpse, whereas *fedet* is produced on the exterior. However, *redju* had more profound associations. The word is thought to come from the Egyptian verb *redi*, "to give," so that *redju* literally means "that which is given." It was occasionally said to be responsible for the rise of the Nile and the inundation. It seems to have been conceived of as a kind of fluid emanating from the Earth at the source of the Nile, which created the life-giving Nile. The Nile may thus have been imagined as an internal secretion or seminal emission of the Earth. However, since efflux from the earlier god Sokar, god of the resurrectable Earth, was also viewed as the source of the Nile, that was probably the original

tradition prior to the Fifth Dynasty, before Osiris became amalgamated with Sokar as Sokar-Osiris. Plutarch specifically writes of the Egyptians: "They call not only the Nile but all moisture generally the efflux of Osiris." The Greek word used by Plutarch for "efflux" is  $aporro\bar{e}$ , which means "a flowing off, stream, efflux, emanation." Plutarch for "efflux" is  $aporro\bar{e}$ , which means "a flowing off, stream, efflux, emanation."

In one Coffin Text, we are told that *redju* was the substance out of which the *ba*-spirit or *ba*-power was formed: "For I am this great ba of Osiris . . . which Osiris had made from the fluid of his corpse, coming from his body." (This reminds us of the Victorian medium's concept of "ectoplasm.") However, in a resurrected body, there is a fine line between the efflux of decay and the efflux of seed ejaculated from the reinvigorated phallus. Both are interior secretions. There are many sacred depictions of Isis fluttering as a ba over the corpse of her husband, Osiris, and settling down on his erect phallus to become impregnated with her son Horus. There was a special verb in Egyptian, sab, which meant "to flow out" or "to flow away," that was used to describe the "flowing away," "streaming," or "flowing out" of the *redju*. Clearly, we have here a concept not too remote from that of "emission," as of sperm. There are at least two Coffin Text spells that associate the "flowing away of the redju" with Anubis and claim that the emitted *redju* was actually called by the name of "jackal." The name "leopard" (sab) was sometimes applied as a pun on the verb sab. This may have been connected with the high priest of Sokar wearing a leopard skin during the Festival of Sokar. What is clear in all of this is that there are many levels of meaning, and that everything related to the decomposition of the body after death was, in a society obsessed with mummification, also associated somehow with its opposite. The Egyptians were always saying that the decomposition products were "hidden," and especially hidden at Rostau. What, therefore, could we really expect to find in a chamber beneath Giza one day? An interesting survey of the concepts of redju was published in 2006 by Andreas Winkler in an article entitled "The Efflux That Issued from Osiris." $\frac{30}{2}$  Winkler mentions that rediv has a restorative function, signified in ritual as a libation, connected with the reassembling of the scattered limbs of Osiris and "that redju is positive for the deceased when the theme of reconstitution dominates . . . " (I have according to my practice in this book rendered *redju* wholly in English letters here, not in the linguistic symbols used by Winkler, which I have eschewed throughout this book because they are incomprehensible to the general reader.) Because I have elsewhere, in a still unpublished work, finally solved the mystery of what was really meant by "the limbs of Osiris," that interpretation opens a new perspective on the concept of what was ultimately meant by redju, but a full explanation must await some future occasion, as it is a lengthy discussion that relies on some complex physical evidence concerning an Egyptian site that affords the "key" to the mystery and its associated secret ritual.

If we ever find and open such a chamber, we should be prepared possibly to find not a grand Hall of Records as many well-wishers imagine, but perhaps a repository of some strange ceremonial fluid, even possibly one containing dangerous substances. The "efflux of Osiris" might be something unpleasant and harmful. There is other evidence suggestive of this, but a discussion of this subject leads us too far astray from our main subject. On the other hand, the "efflux of Osiris" might be "hidden" in its corresponding opposite form, gold. As Zandee says, in quoting one of the Pyramid Texts: "The body of the dead is of gold like that of a god and so it consists of imperishable material. 'Rise on your bones of bronze and on your limbs of gold, for this body of yours belongs to a god. It does not perish. It does not decompose, it does not consume." By not consuming, they mean not eating. If you don't eat, you cannot decay. So perhaps there is a secret chamber beneath Giza that contains the "efflux of Osiris" changed into a gigantic mass of gold. Perhaps this is the true origin of alchemy, where the "essence of gold" can bring eternal life. Alchemy, especially the alchemy of the ancient world (both Western and Chinese), is a subject that I have

studied in a certain amount of depth. I referred to this in passing in my book *The Genius of China* (for instance, in pointing out that gunpowder was discovered by Chinese alchemists), and I have written a large portion of a still unfinished novel on the subject of alchemy, which elucidates many unusual aspects of the subject. Clearly, I cannot discuss such things here, as it would be too great a distraction from our main concerns. However, I am not alone in being convinced that many alchemical processes and traditions originated in Egypt. As recently as 2004, an article appeared in the periodical *Discussions in Egyptology* by Daniel Burnham entitled "Explorations into the Alchemical Idiom of the Pyramid Texts," referring to the earlier work by Jack Lindsay (*The Origins of Alchemy in Greco-Roman Egypt*, 1970), and attempting to explain these matters more fully. Unfortunately, we cannot pursue this discussion, and once again I am forced to touch on the fascinating subject of alchemy only in passing. One must always keep in mind, however, that the "death" of Osiris and his "resurrection," the "essence of gold," golden statues, and all such symbolical matters may conceal allusions to alchemical concepts and practices. It is highly likely that the Philosopher's Stone is originally an Egyptian concept, and that "turning things into stone" for funeral monuments may be associated with this idea. But we must move on.

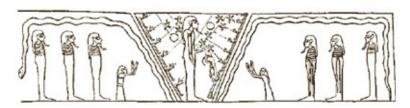

Figure 7.20. In the Tomb of Rameses VI, the central figure has no name. In the Tomb of Rameses IX, another representation of him gives him the name "the One who hides the hours." In fact, this central figure represents the creator god (in this case, Osiris, though originally the creator god was called either Atum or Ptah, depending on whether you were at Heliopolis or Memphis) creating the universe with his sperm by an act of masturbation. In this representation from the tomb of the earlier pharaoh, the scene is not as clear as it is in the Tomb of Ramesses IX, which was beautifully engraved in Description de l'Égypte, Paris, 1809, an engraving I have in my collection and have published with my article "The Prehistory of Panspermia: Astrophysical or Metaphysical?" in International Journal of Astrobiology, 6 (2), pp. 169–180 (2007). (This article discusses ancient theories resembling those of "panspermia," the process by which life spreads throughout the universe by means of tiny seeds, ideas that were held by several ancient cultures such as the Egyptians, the earliest Hindus of India, and the Greek philosopher Anaxagoras.) The picture shows the youthful god Horus being created by a dribble of sperm from the erect phallus of Osiris (here Horus is seen as a dangling infant just below the tip of the phallus). The trails of sperm are seen throughout the sky, passing between various stars of the cosmos and a number of recumbent receiving parties, who are taking divine disks of light into their hands from the trails of sperm. The creator god stands triumphant atop the defeated body of the serpent Apophis, evil retarder of progress, of life, and of resurrection. The reference to the creator god as "the One who hides the hours" refers to the fact that he created the hours, and time itself, when he created the universe, but the secrets of time and the hours are so esoteric that he hides them from the profane, so that they are known only to the highest level of priests. This image represents an amalgamation of an extremely ancient concept of the creation of the entire cosmos with the conception of the rising of the giant Osiris at the horizon, and indeed, it is likely that these were ideas that were always thought of as one during the New Kingdom period. This is figure 95 on page 339 of volume I, Alexandre Piankoff and N. Rambova, The Tomb of Ramesses VI, Bollingen Series 40:1 (New York: Pantheon Books, 1954), 2 vols.

We are assured that if we can gain access to this hidden shrine, we will "live forever." (Careful! "Living forever," to an ancient Egyptian, tended to mean eternal life after death!) And this brings us back to *The Book of the Hidden Chamber*, which has more specific things to say about the mystery of Rostau. This book survives in two versions, the "long" and the "short." But the short version is not simply an abbreviation of the long version; it actually gives a slightly different emphasis to certain things and uses some different textual passages that do not occur in the long version. The only publication of the short version in English was by Budge. In this translation the name Rostau is given in two variations: Re-Statet and Re-Sethau. Here are some of the intriguing remarks that we find there (Budge capitalizes some names):

Whosoever knoweth this representation of the hidden roads of RE-STATET [Rostau], and the holy paths of the AMMEHET, and the secret doors which are in the Land of SEKER [Sokar], the god who is upon his sand, shall be in the condition of him that eateth the bread-cakes which are [made] for the mouth of the LIVING gods in the Temple of Tem [Atum].

Whosoever knoweth this shall be in the condition of him that is  $ma\bar{a}t$  [Cosmic Order, absolute truth] on the ways, and he shall journey over the roads of Re-SETHAU, and he shall see the representations of the AMMEHET [a name for the underworld]. . . . This great god [the sun god at night] is towed along over the ways of Maāt of the Tuat [underworld] through the upper half of this secret Circle of the god SEKER [Sokar], who is upon his sand, and he neither looketh upon nor gazeth at the secret figure of the earth which containeth the flesh of this god. . . . AMENT [the West] is the name of the Circle of this god, [and in it are] the secret path of Amentet [a name for the most secret and hidden part of the underworld], and the doors of the hidden palace, and the holy place of the LAND OF SEKER [with his] flesh, and [his] members, [and his] body, in the divine form which they had at first.

BAIU-AMU-TUAT [the spirits who are in the underworld] is the name of the gods who are in [this] Circle. Their forms (*aru*) who are in their hour, and their secret shapes (*kheperu*) neither know, nor look upon, nor see this image (or, similitude) of SEKER (or, the hawk) himself.

Whosoever shall make these representations according to the image which is in writing in the hidden places of the Tuat, at the south of the Hidden Palace, and whosoever shall know them shall be at peace, and his soul shall unite itself to the offerings of SEKER, and the goddess KHEMIT shall not hack his body in pieces, and he shall go on his way towards her in peace. 33

One detail not to be overlooked in this "short form" of the *Book of the Hidden Chamber* is that the great chamber of mysteries concealed in the Land of Sokar at Giza is here apparently described as being "south of the Hidden Palace." This crucial geographical information does not occur in the "long form" of the same book. This is yet further evidence that these sections were incorporated from some more ancient common text, for otherwise how would the short version contain things that are not in the long version? The short version was obviously a different abridgment of the original source, not an abbreviation of the long version.

What does this mean, "south of the Hidden Palace"? The Hidden Palace might be an appropriate way of referring to the Great Pyramid, as it is the grandest structure to be seen at Giza. In the seventh hour of the same book, there is a reference to "the similitudes which are in writing at the northern side of the Hidden Palace in the Tuat," so these references may be to the northern and southern faces of the Great Pyramid. And what does it really mean when this ancient text says that an initiate should make copies of the pictures relating to Giza, such as the ones hidden north of the Hidden Palace? <sup>35</sup>

Another point we should notice is that in this text it is not the flesh of Osiris that is said to be beneath Giza. Here it clearly says that the buried flesh is the flesh of *Sokar*. At Giza, Sokar was the original god, and Osiris was a form of him that came later. Margaret Murray stresses this when she tells us: "Osiris Sokar . . . the anthropomorphic god of the dead, as identified both with Ptah and with the hawk-headed Sokar; the three together forming the triple god, Ptah-Sokar-Osiris. The dominion of Sokar is given in the 4<sup>th</sup> and 5<sup>th</sup> divisions of the 'Book of Am Duat,' but M. Jequier shows that the dominion of Sokar was originally quite distinct from that of Osiris, and that the two have been incorporated together in the 'Book of Am Duat' by later theologians." <sup>36</sup>

Figure 7.21. The name of the god Osiris, surviving in superb condition on a wall of the temple of Seti I at Abydos. The seated figure of a god on the right is what is called in hieroglyphics a "determinative" sign, which indicates that the name is that of a god. The actual name in Egyptian is generally transliterated as Asar (which is the origin of the Greek form, Osiris). It is symbolized by the two hieroglyphs of an eye and the strange shape on the left, which is thought by Egyptologists to represent a throne. In fact, I do not believe the sign on the left actually represents a throne at all, but something else entirely. I believe it is a specific section of a sacred rectangle, and that it is related both to the archaic sacred rectangular enclosures of the early pharaohs and to certain arcane geometrical conceptions. A vertical line drawn through the pupil of the eye makes a golden angle with a line drawn from the pupil to the tip of the bottom "step" of the rectangle segment. (*Photo by Robert Temple*)

However, the substitution of Osiris for Sokar, which we found so completely done in the Middle Kingdom text, The Book of the Two Ways, that we considered a moment ago, was incompletely done in the New Kingdom text of the short form of *The Book of the Hidden Chamber*. Using the fundamental logic of textual analysis, we do not need to be geniuses to conclude that the short form of The Book of the Hidden Chamber preserves an earlier and unamended form of the tradition, and is thus an earlier text than The Book of the Two Ways. But since The Book of the Two Ways dates from the Middle Kingdom and The Book of the Hidden Chamber dates from the much later New Kingdom, there is only one conclusion that can be drawn here: the "later" text is later only in that it survives from later editions, but it is really earlier. In other words, we have conclusive textual proof that at least the section dealing with Rostau/Giza of The Book of the Hidden Chamber is earlier than the Eleventh Dynasty of the Middle Kingdom (1987– 1938 BC) from which The Book of the Two Ways is known to survive. Since the material must predate 2000 BC and the Middle Kingdom, and since it cannot possibly have come from the First Intermediate Period (2180–1987 BC) before that, due to the total collapse of Egyptian civilization at that time of social chaos, it must therefore predate 2200 BC and be of Old Kingdom date. This places it no later than the Sixth Dynasty and the Pyramid Texts and means that it is equal in age to those oldest-known Egyptian religious texts. However, I have taken a rather conservative approach to tracking the date of the text. One distinguished German Egyptologist, H. Altenmüller, hasn't bothered with such niceties, and says without a blush that he thinks the text comes from the Fourth or Fifth Dynasties (2640–2360 BC)!<sup>37</sup>

Figure 7.22. Here the priests of Sokar, the original lord of the underworld (whose position was later taken by Osiris), are seen carrying the Sokar barque in procession at Giza during the annual Sokar Festival, when they made a circuit with it of the sacred areas near the Sphinx. The strange object with a bird's head sitting in the middle of the barque is a fetish that represents Sokar, in the form of a mummified hawk, with his head protruding from the mummy wrappings. The third priest from the left is wearing an animal skin (which we know from other depictions to be a leopard skin, though the spots are not visible in this picture) over his shoulder, and the medallion suspended on his chest shows that he is the chief priest of the group, while the priest behind him appears to be his deputy and carries a sacred wand or scepter. The two main priests in the center are not sharing in the actual bearing of the load, which is borne by the four groups of four junior priests, suggesting that as sixteen men were needed to carry it, the boat must be heavier than it appears. The exact nature of the Sokar fetish is not known, and the huge mummified portion may have contained something secret and concealed beneath the wrappings. My theory about this fetish is that a solid gold statue of Sokar was concealed inside, making the barque extremely heavy. This gold statue would have been the central cult statue of the god, normally kept in the inner sanctum of the temple. When carried outside once a year, it had to be concealed from the eyes of the profane, and it also could not be exposed to the light of the sun, because Sokar was known never to emerge from his perpetual darkness. The small Sokar-head on top of the fetish serves merely to identify the fetish so that people can realize that the true Sokar is concealed inside the mummy wrappings, in keeping with his nature. This engraving of a temple carving was published in 1809 in Description de l'Égypte, before the decipherment of hieroglyphics, but care was taken to engrave correctly the two hieroglyphs in front of the chief priest, which read sem. This specifically identifies the chief priest in the picture as a Sem priest, and that means that we have here a picture of the high priest of Ptah from the Temple of Ptah at nearby Memphis, in his role as head mortuary priest, or Sem priest, of Sokar. Ptah and Sokar were merged as a joint divinity at Giza. Later the divinity was called Ptah-Sokar-Osiris and became a sacred trinity. The location of this temple carving is unknown, and it has possibly perished since this drawing of it was made prior to 1809. It is possible that it was carved on one of the walls of the Temple of Ptah but was among the vast amount of stone carried away from Memphis and Giza for use in the construction of mosques and palaces in Cairo during the nineteenth century. (Collection of Robert Temple)

Thus, whatever this section dealing with the fourth and fifth hours of the underworld contains, it is truly ancient and has a claim on our attention as possibly containing accurate details relating to some of the mysteries of Giza.

Let us therefore look even more closely at the intriguing short form of *The Book of the Hidden Chamber*. The text specifically refers to "the secret figure of the earth" being on the surface at Giza, above the hidden chamber of Sokar. This reminds us of the many interpretations of the measurements of the Great Pyramid as representing the precise size of our globe. This text could reasonably be claimed as near-contemporary evidence, dating at least from the Old Kingdom, of a description of a major structure on the surface at Giza that was considered to represent the secret figure of the Earth, and therefore to substantiate with textual evidence all the physical evidence that has been so fully brought forward by those who insist that the Great Pyramid is indeed a secret figure of the Earth.

The first to propose this extraordinary hypothesis was the French scholar Edmé-François Jomard, who accompanied Napoleon to Egypt in 1798. Jomard was concerned with the height of the Great

Pyramid, and he calculated the height of the apothegm (the central line going up the middle of any of the sides) as being 184.722 meters. This was the "slant height" of the pyramid, which by means of trigonometry could help calculate the vertical height. Here is how Peter Tompkins, in *Secrets of the Great Pyramid*, describes what happened next:

Jomard remembered that according to Diodorus Siculus and Strabo, the apothegm of the Pyramid was supposed to be one stadium long. He also knew that an Olympic stadium of 600 Greek feet—from which our modern sports stadium is derived—was a basic unit of land measure in the ancient world, one which was said to be related to the size of the earth. . . . Searching further through the trunks full of classics which the savants had brought to Egypt, Jomard found that the stadium of the Alexandrine Greeks [in Egypt] . . . had been the equivalent of 185.5 meters—which was within a meter of what he had found for the apothegm.

To reinforce the point, Jomard discovered that the distance between the Egyptian localities as measured by Napoleon's surveyors also coincided with the classical distances between these localities computed in stadia, if the stadium was taken to be 185 meters.

Finally, Jomard learnt from his perusal of the classics that a stadium of 600 feet was considered to be 1/600 of a geographical degree.

Jomard calculated that a geographical degree at the mean latitude of Egypt was 110,827.68 meters. Dividing this figure by 600 resulted in a measure of 184.712 meters. This was within 10 centimeters of his value for the apothegm.

Could the Egyptians, Jomard wondered, have been capable of working out their basic units of measure—such as the stadium, the cubit, and the foot—from the size of the earth and then built this into the Pyramid?

To reinforce this exciting hypothesis Jomard found that several Greek authors reported that the perimeter of the base of the Pyramid was intended to measure half a minute of longitude. In other words, 480 times the base of the Pyramid was equal to a geographical degree.

Jomard took the 110,827-meter degree and divided it by 480. The result was 230.8 meters, or again within 10 centimeters of his measured length of the base [of the Great Pyramid]. . . . To the end, Jomard remained convinced that the builders of the Pyramid had the necessary astronomical knowhow to measure a geographical degree and thus the true circumference of the earth, and had developed an advanced science of geography and geodesy which they had immortalized in the geometry of the Great Pyramid. . . . Jomard's classically indoctrinated colleagues could not stomach the idea that their cherished Greeks might not be the founders of geometry; so the pursuit was dropped. 38

There are obviously more details to this than I have given, but we do not need the full mathematical account to get the idea. Jomard's hypothesis was not at all outrageous, really, for it had a good pedigree in statements made by various ancient authors. It did not just come out of his head, but was forced upon him by his work. And Jomard was not tainted at all with "Bible mania," as so many of the English authors who wrote about the Great Pyramid were. For some reason, the French were much more sane and did not drag their religious fantasies into their Egyptian studies in the way that the English and the Scots, and many religious Americans, repeatedly did.

The next scholar to consider seriously the theory that the Great Pyramid represented the northern hemisphere of the Earth in symbolic form was John Taylor, in his fascinating book *The Great Pyramid*:

Why Was It Built? And Who Built It? published in 1859. It took me a very long time to obtain a copy of this book, as it is so rare. Taylor's book is really very thought provoking. One of his curious discoveries, it turns out, can be interpreted only on the basis of something I published in my own book *The Crystal Sun* 141 years later, in 2000.<sup>39</sup> By that time, alas, it was too late to inform Taylor! But he discovered the very strange fact that two prominent ancient Egyptian units of measurement differed from each other by the tiny amount of 1.01. He was justly puzzled by this. In *The Crystal Sun* I explain that the precise number that we write in our modern decimal notation as 1.0136 (but that the Egyptians expressed as a fraction) was "the greatest secret of the ancient Egyptians," well known to them from its connections with both musical theory and the calendar, and so it is not at all surprising that the same number was embodied in their system of sacred measurements (although as I did not yet have Taylor's book, I was unable to mention it in *The Crystal Sun*). I have returned to this subject of measurements in my book *Egyptian Dawn*. But in the meantime, to retain the thread of our thoughts, I want to show how Taylor conceived of the Great Pyramid as what the ancient text calls "a secret figure of the earth":

The angle of the casing-stones being 51° 50' . . . What reason, it may be asked, can be assigned for the founders of the Great Pyramid giving it this precise angle, and not rather making each face an equilateral triangle? The only one we can suggest is, that they knew the Earth was a sphere; that they had measured off a portion of one of its great circles; and by observing the motion of the heavenly bodies over the earth's surface, had ascertained its circumference, and were now desirous of leaving behind them a record of that circumference as correct and imperishable as it was possible for them to construct. They assumed the Earth to be a perfect sphere; and as they knew that the radius of a circle must bear a certain proportion to its circumference, they then built a Pyramid of such a height in proportion to its base, that its perpendicular would be equal to the radius of a circle equal in circumference to the perimeter of the base. To effect this they would make each face of the Pyramid present a certain ascertained angle with reference to its base (supposing a vertical section made of it), which angle would be that of 51° 51′ 14," if modern science were employed in determining it. . . . Now the actual angle of the casing-stones was found to be 51° 50.' Can any proof be more conclusive than this, that the reason we have assigned for the construction of the Great Pyramid was the true reason which influenced its founders? How the thought occurred to them we cannot tell; but a more proper monument for this purpose could not have been devised than a vast Pyramid with a square base, the vertical height of which Pyramid should be the radius of a sphere in its circumference equal to the perimeter of that base. It was impossible to build a hemisphere of so large a size. In the form of a Pyramid, all those truths might be declared which they had taken so much pains to learn; and in that form the structure would be less liable to injury from time, neglect, or wantonness, than in any other.  $\frac{40}{100}$ 

If Taylor had known that the short form of *The Book of the Hidden Chamber* dating from the Pyramid Age had mentioned a structure at Giza that was called "the secret figure of the earth," he would have jumped for joy, for this was precisely what he had decided the Great Pyramid really was. Those who are determined to believe that the Great Pyramid was built as a pharaoh's tomb can still retain their belief and at the same time admit that the Great Pyramid was also a "secret figure of the earth," since the two intentions are not in any way incompatible with one another. After all, a pharaoh can be buried in a pyramid that either is or is not a "secret figure of the earth," as the symbolic message of the structure would not interfere with his eternal rest. I personally do not accept the theory that the Great Pyramid was ever built to be a tomb and have already called attention to the fact that Herodotus specifically stated that it was not one. It may have been intended as a dummy tomb or a symbolic tomb, but I am certain that it

was never a real tomb. I do not believe the empty sarcopohagus in the King's Chamber ever held a corpse. One of the curious things about that sarcophagus is that it is too large to fit through the door, so it can never have been carried in. In *The Crystal Sun* I discuss numerous strange aspects of the King's Chamber, which I will not repeat here.

In *Secrets of the Great Pyramid*, Peter Tompkins also gives prominent attention to John Taylor's pioneering work, although he was unaware that the book was published in 1859 and knew only a subsequent edition of 1864. Tompkins's account, as usual, is very amusing:

Taylor then discovered that if he divided the perimeter of the Pyramid by twice its height, it gave him a quotient of 3.144, remarkably close to the value of  $\pi$ , which is computed as 3.14159+. In other words, the height of the Pyramid appeared to be in relation to the perimeter of its base as the radius of a circle is to its circumference.

This seemed to Taylor far too extraordinary to attribute to chance, and he deduced that the Pyramid might have been specifically intended by its builders to incorporate the incommensurable value of  $\pi$ . If so, this was a demonstration of the advanced knowledge of the builders. . . . Searching for a reason for such a  $\pi$  proportion in the Pyramid, Taylor concluded that the perimeter might have been intended to represent the circumference of the earth at the equator while the height represented the distance from the earth's center to the pole.

Perhaps Jomard had been right: perhaps the ancient designers had measured the length of a geographical degree, multiplied it by 360° for the circumference of the globe, and by the  $\pi$  relation had deduced the polar radius of the earth, immortalizing their knowledge by making the circumference to scale with the perimeter and the radius to scale with the height of the Pyramid. Taylor underlined his thesis: "It was to make a record of the measure of the Earth that it was built."

In other words, it was what *The Book of the Hidden Chamber* calls a secret figure of the earth.

Having now dealt with this subject by way of an introduction to some of the more ambitious measurements and designs that may possibly be incorporated into the various structures of the Giza Plateau, it is time to explore the interrelationships of those structures in space, and specifically those that affect the Sphinx. My next book, *Egyptian Dawn*, contains extensive discussion of the pyramids themselves, but Sphinx matters are dealt with in this book. In *The Crystal Sun*, I already put forward the evidence that the Pyramid of Chephren was built where it was, and to the size it was, for a very important reason, and as part of a larger plan linked to that of the Great Pyramid. The photo in figure 3.10 of this book shows the shadow cast by that pyramid onto the south face of the Great Pyramid at sunset near the time of the winter solstice, similar to one I published in *The Crystal Sun*, and I have already discussed in *The Crystal Sun* its significance in terms of the placing of the Pyramid of Chrephren on the plateau. What about the Sphinx? Are there any determining factors in terms of the other monuments on the Giza Plateau that might be held to specify both its position and its size? As it happens, there are.

In chapter 3, I described my discovery, by means of a scientific instrument called an inclinometer, when I took a sighting through the instrument of the tip of the Pyramid of Chephren while I was standing on the floor of the Sphinx Temple. By reading the information given by the inclinometer, I discovered that the line of sight made the unique sacred angle of the Egyptians of 26° 33' 54" (which we call the golden angle, as it is the only angle produced in the only triangle, the "golden triangle," that can be constructed by means of the Golden Section) with the base of the temple. I could not be as precise as measuring the 54 seconds, but it was clear that the golden angle was intended. This did not surprise me, because I had

already discussed the golden angle at such length in my earlier book *The Crystal Sun*, where, as I have already mentioned, I published a photograph (and another is now published here as I just said) showing that angle being cast as a shadow onto the south face of the Great Pyramid at sunset on the winter solstice (a shadow cast by the nearby Pyramid of Chephren). This was the largest and most dramatic physical indicator of the importance of a solstice in the whole of the ancient world. It is shown in figure 3.9, and I have reproduced again the color photo from that book on this book's website. My discovery was of particular importance because it is the same angle of inclination of both the Ascending and Descending Passages inside the Great Pyramid, thus hinting on the outside at what lay on the inside. This is the kind of mysterious behavior that so delighted the ancient Egyptian priests. I also reported in that book my discovery that the ascending passage that leads out of the Valley Temple onto the Chephren Causeway was inclined at the same golden angle (see figure 7.23). That passage is what I call a golden slope, which is the name I give to a slope that rises or descends at a golden angle to the horizontal plane. (Both the Ascending Passage and the Descending Passage of the Great Pyramid are therefore what I call golden slopes.)

Figure 7.23. This is the ascending passage that leads out of the back (west end) of the Valley Temple at Giza, onto the Chephren Causeway, in the direction of the Pyramid of Chephren. Its floor is of Egyptian alabaster and its walls are of red granite. I measured the angle of its slope and found that it was the golden angle, identical to the slopes of both the Ascending and Descending Passages inside the Great Pyramid. I was the first person to notice this golden angle in the Valley Temple. Because golden triangles (a golden triangle as I use the term being a right triangle with a golden angle as its acute angle opposite the altitude) were so important at Giza, I am certain that there is a subterranean crypt beneath this passage, which has probably been sealed since Old Kingdom times. That is because when they have a golden slope, the Egyptians always have a golden triangle as well, with that slope constituting the triangle's hypotenuse. And when an enclosed space falls below that slope, there tends to be a chamber, because it is a sacred spot. The so-called Grand Gallery inside the Great Pyramid is the hypotenuse of a golden triangle which defines the location of the so-called Queen's Chamber, with the passage leading to it as one of the sides of the triangle and the chamber itself being situated at the base of the right angle (see figure 54 in my book *The Crystal Sun*). I believe that the probability of there *not* being an important chamber beneath the doorway at the top of this ascending passage is zero. (*Photo by Robert Temple*)

Figure 7.24. This photo is taken from the top of the Valley Temple looking up toward the Pyramid of Chephren along the limestone Chephren Causeway. As can be seen, the causeway is at an odd angle (not the golden angle) to the pyramid, and also to the temple, and no one has ever explained why. The ascending passage arising out of the Valley Temple and leading to the back doorway that opens onto this causeway (see figure 7.23) is on a slope that *is* the golden angle, identical to the slope of the Ascending and Descending Passages inside the Great Pyramid. The line of sight that passes through the air from the top of the Pyramid of Chephren to the floor of the Sphinx Temple is also at the golden angle (as I measured with an engineer's device called an inclinometer), as shown in figure 3.13. The shadow cast by the Pyramid of Chephren at sunset of the winter solstice upon the south face of the Great Pyramid also forms a golden triangle, with its hypotenuse forming the golden angle (see figure 3.10, and also plate 30 in my book *The Crystal Sun*). The exact position and size of the Sphinx are also determined in relation to the two main pyramids by multiple golden angles, as shown in figure 7.25. All three of these key monuments had to be placed exactly where they are and had to be exactly the sizes they are as part of a unified conception based on geometric principles. (*Photo by Robert Temple*)

In *Egyptian Dawn* I give a large number of new discoveries concerning the unified design concept of the Great Pyamid's interior structure. Many of these discoveries have nothing whatsoever to do with the Golden Section, and are straightforward design criteria of a remarkable kind that no one had ever noticed before. There is a second category of design criteria, however, that is wholly connected with the Golden Section. The categories appear to be separate, as if one was superimposed upon the other, thus offering two separate "stand-alone" levels of discoverability to the investigator, one that gives the impression of having been designed to be "idiot-proof" for the most basic investigator to find and one at a higher level of difficulty. I felt as if I was decoding two separate levels of design information, and doubtless there is more to find! Someone really clever now needs to come along and figure out the rest of it, such as what it all means and what it was for!

One reason for bringing the Great Pyramid into the discussion in this chapter is to lay the basis for revealing a hitherto-unnoticed connection between the precise location of the Sphinx and that wonderful structure the Great Pyramid, for the Sphinx's size, general shape, and location are all determined directly by its relationship to the Great Pyramid, as we will now see, and as is made clear in figure 7.25. No one has ever noticed this before, because it is not at all obvious.

In figure 7.25 I reproduce part of the official Egyptian government geodetic survey map of the Giza Plateau, of the sort that in Britain is called "an ordnance survey map," which may be presumed to be as accurate as any other map of the Giza Plateau in existence. It is certainly more reliable than any of the plans prepared by archaeologists, which I have found are often misleading and lacking in accuracy.

I have overlaid across the map in figure 7.25 various lines connecting key points of monuments on the Giza Plateau, and where the golden angle recurs frequently. It is in fact a dominant motif of the entire Giza Plateau Plan.

We can see that the size of the Sphinx is determined first of all by three rays emanating at an identical angle, the "golden angle," from three separate key points of the Great Pyramid and striking it at its own

defining points, namely front, midpoint, and rear. The first of these emanates from the northeast corner of the Great Pyramid. This makes a golden angle with the north–south meridian that defines the east face of the Great Pyramid, and it shoots off toward the Sphinx and strikes the northeast tip of that monument, which is the left tip of its left paw. In other words, this ray connects the northeast corners of both monuments with a line drawn at the golden angle to a north–south meridian at either point.

The second defining ray emanates from the midpoint of the base of the Great Pyramid's eastern face. It strikes the midpoint of the Sphinx. This ray also makes a golden angle with the north—south meridian at either point.

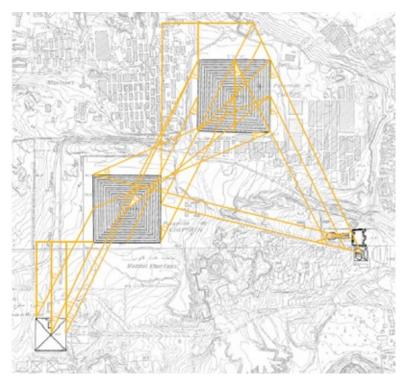

Figure 7.25. This is the Golden Giza Plan, which I worked out laboriously and with the greatest of difficulty. To achieve accuracy, it was necessary for me to work out these geometrical relationships using the official Egyptian government survey map, which is the black-and-white basis for this two-color diagram. The golden lines show what I have chosen to call the "rays" connecting the four key monuments. All of these rays share the same angle, the golden angle of 26° 33' 54", which is the acute angle occurring in a golden triangle, a right triangle formed on the basis of the Golden Section. The ancient Egyptians were clearly obsessed with the golden angle and embodied it superstitiously in all of their sacred art and architecture. (*Drawing of the rays by Daud Sutton from my sketch, copyright by Robert Temple*)

The third defining ray emanates from the midpoint of the base of the Great Pyramid's northern face. It strikes the southwestern tip of the Sphinx's rump. This ray also makes a golden angle with the north—south meridian at either point.

These three defining rays fix the size and position of the Sphinx. A further defining ray emanates from the Pyramid of Chephren. A ray from the northwest corner of that pyramid parallel with the Chephren Causeway shoots through the midpoint of the Sphinx. (The midpoint of the Sphinx is thus an intersection point of two rays shooting from key points of the two separate pyramids. The latter ray also makes a golden angle, which is described in a moment.) The northwest corner of the Pyramid of Chephren is linked to the midpoint of the base of the Great Pyramid on its eastern face (a point from which a ray is emitted defining the Sphinx's midpoint by a golden angle, as already mentioned), by a further golden angle, this time one made with the east—west line defining the northern face of the Pyramid of Chephren.

The midpoint of the Sphinx is thus one vertex of a triangle, the other two vertices of which are the northwestern corner of the Pyramid of Chephren and the midpoint of the eastern baseline of the Great

Pyramid. Each of these vertices is connected by a previous relationship based upon rays of golden angles.

In other words, there is a kind of interlocking grid of these rays whereby they seem to confirm each other by repeating the same golden angle each time. The ray emanating from the midpoint of the base of the northern face of the Great Pyramid also passes through the southeastern corner of that pyramid on its way to strike the Sphinx's rump at its southeastern tip.

If we look at figure 7.25, we can see that the midpoint of the base of the northern face of the Great Pyramid also shoots a ray toward the Pyramid of Chephren, which strikes it at the point where the southern edge of the Chephren Causeway, which I call the *base* of the Causeway, would strike that pyramid if continued. And this ray then makes a golden angle with the north–south meridian defining the base of the eastern face of the Pyramid of Chephren, yet another confirmation of an interlocking Golden Grid.

But there is something even more remarkable about this midpoint of the base of the northern face of the Great Pyramid: the two rays just described cross the southwestern and southeastern corners of the Great Pyramid, respectively, and in doing so they create a superimposed triangle upon the plan of the Great Pyramid that has as its vertex at the northern face a double golden angle (i.e., an angle that if bisected yields two golden angles). In other words, the rays both make golden angles at the vertex with the north—south meridian bisecting the Great Pyramid. No one has ever noticed before that the size and the distance of the base of the Great Pyramid are just right to do this. The same would apply to rays generated at any of the four midpoints: each would generate two golden angles with rays striking the appropriate corners of the pyramid. I have not bothered to show these on the Golden Giza Plan of figure 7.25, because it complicates the design too much with details that do not concern the Sphinx, however important they may be with regard to the Great Pyramid itself. However, the two descending rays from the midpoint of the base of the northern face show clearly what the other three midpoints also generate with their own pairs of rays, which are omitted from this particular diagram to avoid confusing the reader with too much information.

A large number of other golden angle rays exist that connect the four main monuments of Giza: the three main pyramids and the Sphinx. These demonstrate conclusively that the Giza complex was conceived as a unity and that the sizes and positions of the four monuments are rigidly determined by these sighting rays based upon what I call a Golden Giza Plan. In addition to this, we must remember that there is the golden-angled ray that actually shoots through the air from the floor of the Sphinx Temple, which strikes the peak of the Pyramid of Chephren, as already described in a previous chapter, discovered by me using a device called an inclinometer. And just to set the scene appropriately, we ascend on a golden slope rising at the golden angle up the ascending passageway of the Valley Temple to enter upon the Chephren Causeway and approach the plateau. Truly, Giza is golden!

Now we will look at some of the other golden rays of Giza, in order to explore further the rigidity and inflexibility of this geometrical structure created by some ancient designer or designers who was/were obsessed with golden angles. The three main pyramids at Giza are mutually fixed in their sizes and positions by a complex set of golden rays, as is shown in figure 7.25.

Another golden angle is the one made by the ray shooting from the southeast corner of the Pyramid of Chephren to the tip of the Great Pyramid. It makes a golden angle with the north—south meridian defining the base of the east face of the Pyramid of Chephren.

Yet another golden angle exists between the north–south meridian bisecting the Mycerinus Pyramid and a ray shooting from the tip of that pyramid to the southwest corner of the Pyramid of Chephren.

Another golden angle appears when we shoot a ray from the northwest corner of the Pyramid of

Chephren to the midpoint of the base of the east face of the Great Pyramid. This line makes a golden angle with the east—west line defining the base of the north face of the Pyramid of Chephren.

There are two more rays at golden angles connecting key points on the Great Pyramid with the tip of the Pyramid of Chephren (which was at a golden angle to the floor of the Sphinx Temple, as I have already described). If we shoot a ray from the northwest corner of the Great Pyramid to the tip of the Pyramid of Chephren, it makes a golden angle with the north—south meridian defining the base of the west face of the Great Pyramid. And if we then shoot a ray from the tip of the Pyramid of Chephren to the midpoint of the base of the east face of the Great Pyramid, we discover that it makes a golden angle with the line I have just mentioned.

Yet another golden angle occurs if we shoot a ray from the southeast corner of the Great Pyramid to the midpoint of the base of the west face of the Pyramid of Chephren. It makes a golden angle with the east—west line defining the base of the south face of the Great Pyramid.

Another ray shooting from the northwest corner of the Pyramid of Mycerinus to the midpoint of the base of the west face of the Pyramid of Chephren makes a golden angle with the north—south meridian defining the base of the west face of the Pyramid of Mycerinus. (The same line also obviously makes a golden angle with the north—south meridian bisecting the Pyramid of Mycerinus, which it intersects, and which itself is the base of another triangle with a golden angle, as already indicated, and additionally it makes a golden angle with the north—south meridian defining the base of the western face of the Pyramid of Chephren when it strikes it.)

Another ray shooting from the northeast corner of the Pyramid of Mycerinus to the northwest corner of the Great Pyramid makes a golden angle with the north—south meridian defining the base of the east side of the Mycerinus Pyramid. The midpoint of the base of the west face of the Great Pyramid shoots a ray to the midpoint of the base of the south face of the Pyramid of Chephren, which makes a golden angle with the north—south meridian that defines the base of the west face of the Great Pyramid.

A ray shooting from the midpoint of the base of the east face of the Pyramid of Mycerinus to the eastern edge of the tip of the Pyramid of Chephren forms a golden angle with the north—south meridian defining the base of the east face of the Pyramid of Mycerinus. That same ray then continues on to the northwest corner of the Great Pyramid, where it forms a golden angle with the north—south meridian defining the base of the western face of the Great Pyramid.

If we draw a straight line connecting the three key defining points of the Sphinx (northeast tip, midpoint, and southwest tip) and continue it slightly to the southwest so that it touches the southern edge of the Chephren Causeway (which I call the *base* of the Causeway), we see that it makes a golden angle with the base of the Causeway. It also makes a golden angle with the ray shooting from the northwest corner of the Pyramid of Chephren to the midpoint of the Sphinx.

A line drawn from the point where the Chephren Causeway's base, if extended, would strike the Pyramid of Chephren makes a golden angle with the north—south meridian defining the base of the east face of the Pyramid of Chephren when it shoots off to strike the midpoint of the base of the northern face of the Great Pyramid, passing across the southeast corner of the Great Pyramid as it does so.

We can thus see that the Chephren Causeway, which runs at a rather odd angle of about 14° to the horizontal (east—west line), is actually linked to the Sphinx by two golden angles and to the Pyramid of Chephren and Great Pyramid by one golden angle, so it is not as haphazard as it might superficially seem.

The following key points of the Giza pyramids are thus found to be mutually defined by a bewildering multiplicity of rays, or sighting lines, shooting out at golden angles:

- Great Pyramid: all four corners, the top, and three midpoints
- Pyramid of Chephren: all four corners, the top, and two midpoints
- Pyramid of Mycerinus: two corners, the top, and one midpoint

The decrease in number of salient midpoints in the progression 3, 2, 1 matches the degree of hierarchical size of each pyramid in the group.

We must not forget that the Great Pyramid itself is full of golden angles and golden triangles and golden sections. I have described them at some length in The Crystal Sun. The commencement of the Grand Gallery inside the Great Pyramid is, for instance, determined by a golden triangle. The Ascending Passage and the Descending Passage inside the Great Pyramid are both golden slopes, each at the golden angle of 26° 33′ 54″ to the horizontal plane. It was Petrie who specified this, for the interior slopes of the Great Pyramid are often given as slightly different than the golden angle value. A fuller discussion of this apears in *Egyptian Dawn*, with extensive detail and references and translations of key German texts that are unknown to English-speaking scholars. The fact that the Descending Passage was at this angle was first discovered in the nineteenth century by Henry Crichton Agnew (born 1797), whose largely forgotten work at Giza is discussed in *Egyptian Dawn*. The King's Chamber has multiple golden angles determining its size and shape. As I have already published diagrams elsewhere showing all of these things, I will not discuss them again here. However, for a full understanding of the golden angles of Giza, it is necessary to have a copy of *The Crystal Sun*. In addition to these, there are the eight golden angles manifested on the plan of the Great Pyramid by triangles described a few moments ago, only one of which is actually shown in figure 7.25 (the triangle drawn between the southwest and southeast corners of the pyramid and the midpoint of the base of the northern face).

You do not have to be particularly astute to see that the ancient Egyptians were clearly obsessed with golden angles to an extent that is mind-boggling to us today. It is as if they had gone mad. How could anybody who was not an obsessive— compulsive personality construct a design for the Giza Plateau such as this? All these monuments that had never before been recognized by us as having any coherent design connection with one another are seen really to be interrelated by a crazy array of rays shooting out at golden angles in every direction, which constitute a vast secret pattern that can be seen and plotted only on an official government geodetic survey map. It is such a crisscrossing spider's web that the concealed structure is hard to grasp. We have to remember that all these many rays are determined by *one identical angle*, repeated over and over again.

The question arises: *How did the ancient Egyptians do this?* 

We may not know how, but it is easier to understand why. So we will now turn to that easier question, though in doing so things will become far weirder than fiction, so hold on to your *nemes* headdresses as we take off!

Before we can really comprehend what was going on at Giza, we have to stop to think for a moment: What was the golden angle? And how can you find it? After all, as it is not a whole angle but is 26 degrees plus slightly more than half a degree more, how did the Egyptians know about it in the first place? Were they really that sophisticated? I think a moment's reflection on the last question will permit anyone to answer a resounding "Yes!" Anyone who can build the Great Pyramid can certainly work out an angle in geometry!

As I explain later, the distinguished Egyptian historian of ancient Egyptian architecture, Professor Alexander Badawy, found incontrovertible proof that the Egyptians used a series of numbers that we call

the Fibonacci series in constructing their sacred temples. To prove this, he studied more than fifty ancient structures and measured them very carefully. The successive numbers in this series, as they get larger and larger, converge on a fraction (expressed by us as a decimal, 0.618, which is the decimal portion of 1.618, which is a universal natural constant also called *phi*) that expresses the golden section (which then gives the golden angle) in numerical form. (I call the decimal portion the "golden particle.") All you have to do then is to apply the number to a geometrical line, and you have the golden section without the need to construct it geometrically. It is handed to you on a plate by the number series, a number series that we know they used. You do not even have to be a geometer to get the golden section! However, the Egyptians were also expert geometers, so they probably knew about both the number-series method and at least one of the geometrical methods.

One way to approach the problem of the golden angle is to go back to Euclid (a Greek who flourished 323–283 BC and lived at Alexandria in Egypt). He gives the method for cutting a line in the golden section in a rather ingenious and unusual way. This is found in Book Six of his *Elements*. Book Five of the *Elements* is concerned with defining and explaining what ratios and proportions actually are. In Greek, a ratio was a *logos* and a proportion was an *analogon*, which was a contraction of *ana logon*, meaning "in proportion." (I have recently registered a website called www. inproportion.org, which will be devoted to "sacred" geometry, by the way. Check it out.) This fifth book of Euclid is actually suspected of having been written by a distinguished Greek predecessor, Eudoxus, and Euclid merely incorporated it into his compendium, as there was little or nothing that needed to be added or touched up. Definition 3 of Book Five states: "A ratio is a sort of relation in respect of size between two magnitudes of the same kind." Definition 6 states: "Let magnitudes which have the same ratio be called proportional." This may all sound very simple and obvious, but the Greeks were very thorough, and they did not believe in writing books about things unless they first defined what they were talking about.

Book Six then moves on to what concerns us. What we call the golden section was not called that then; it was merely called "the section." But Euclid discusses it in a more fundamental manner still, and calls it "the extreme and mean ratio." Definition 3 of Book Six states: "A straight line is said to have been cut in extreme and mean ratio [akron kai meson logon] when, as the whole line is to the greater segment, so is the greater to the less." Bearing in mind the second definition we saw from Book Five, we can realize that this comparison of two ratios means that we are dealing with a proportion. Hence we tend to call it today "the golden mean proportion," though that is modern language adopted during the nineteenth century, not Euclid's language. (In the Renaissance, it was called "the divine proportion.")

The demonstration of how to find the golden mean proportion is then given by Euclid in Book Six, Proposition 30, which is called: "To cut a given finite straight line in extreme and mean ratio." Euclid then proceeds to go about it, draws a figure, and so on, in his usual way. What is so intriguing about the way he does this is that he does not follow the more modern methods at all, but approaches the matter in the manner of a man who thinks entirely differently from moderns. His method is incredibly simple when you read it, though how anyone discovered it in the first place is baffling, so one must presume mere trial and error. To summarize, what it amounts to is this: draw a square, then draw any parallelogram that shares a corner with that square and is equal to the square in area, and it will of necessity cut the square at a point that is the golden section of the side of the square that is cut. (The details of what a parallelogram is, and of how to make it equal to the square, and so forth, are all things that Euclid has dealt with earlier, so that the student marching his way through the *Elements* always follows a clear cumulative path of definitions and explanations and knows exactly what is going on at every step, like a baby led by the hand who is being taught how to walk.)

By way of illustration of Euclid's method, I reproduce in figure 7.27 the page from one of the most amazing books about geometry ever published, Oliver Byrne's *The First Six Books of the Elements of Euclid*, William Pickering, London, 1847. Because the book is so unusual, I am reproducing its title page also, in figure 7.26. Byrne pioneered a color-coded method of understanding geometry at the remarkably early date of 1847, and this is one of the rarest books on geometry in the world, of which I have been fortunate to obtain a copy. On my website figure 7.26, the method of Euclid for obtaining the golden section, is shown in full color. It would take too long to explain Byrne's system of color-coding, but the diagram on the left of the page shows the result very vividly. Maybe somebody will publish a reprint of this extraordinary book in full one day, as a copy should be in the hands of everyone with a true interest in such things.

Figures 7.28 to 7.30 and 7.32 reproduce diagrams showing more "usual" modern methods of determining the golden section. However, it is not necessary for me to go into further detail about these geometrical techniques; I merely wish to indicate them. Serious students of geometry either already know them or can easily find them in standard works of reference.

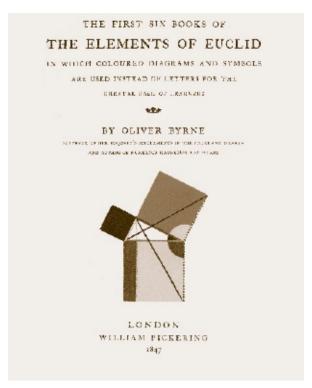

Figure 7.26. The title page of Oliver Byrne's innovative color-coded excursion into Euclid's geometry, which attempts to make the geometrical principles clear to people who are uneasy with equations and standard diagrams, by showing what is happening in different colors. Byrne's thinking was that artists would intuitively grasp the geometry if color was used in this way. His book was a monumental step in the history of printing for the mid-nineteenth century. (For a full-color version of this illustration, visit my website.)

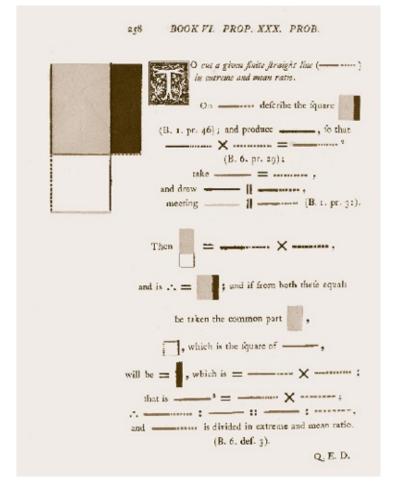

Figure 7.27. Oliver Byrne's depiction in color codes of what happens when you find the golden section of a line (by "cutting it in extreme and mean ratio," as the mathematicians like to express it), according to Euclid, Book Six, Proposition 33. (For a full-color version of this illustration, visit my website.)

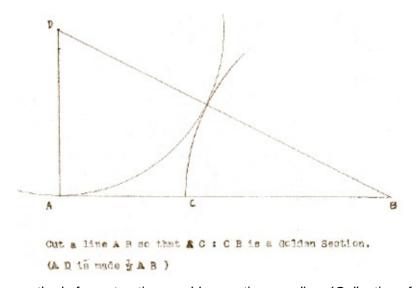

Figure 7.28. One method of constructing a golden section on a line. (Collection of Robert Temple)

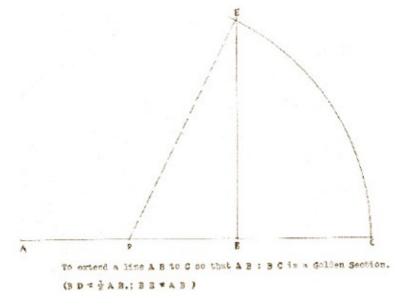

Figure 7.29. Another method of constructing a golden section on a line. (Collection of Robert Temple)

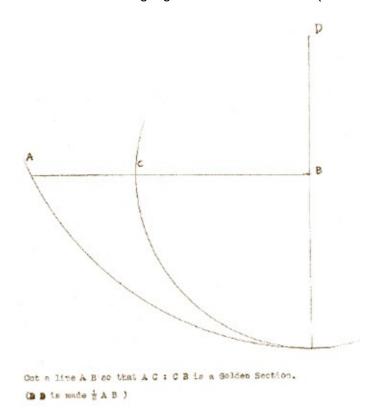

Figure 7.30. Athird method of constructing a golden section on a line. (Collection of Robert Temple)

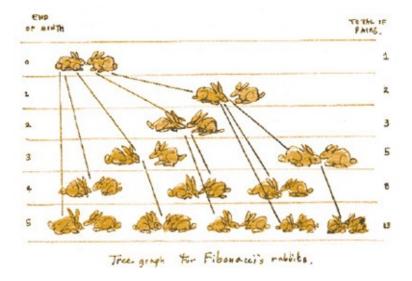

Figure 7.31. A drawing showing how rabbits breed according to the numbers of the Fibonacci series, which are related to the golden section. The Fibonacci-series numbers were used for the layout of ancient Egyptian temples, a fact proved by Professor Alexander Badawy (see page 381). (*Collection of Robert Temple*)

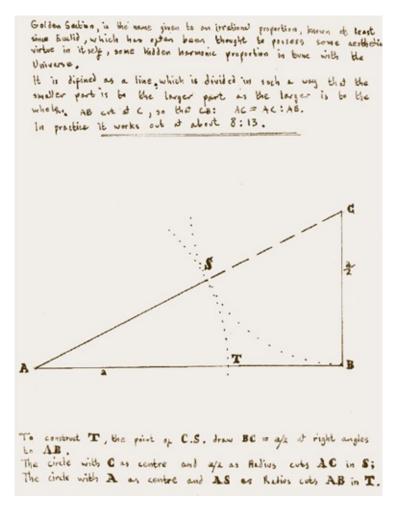

Figure 7.32. Notes and demonstration of the construction of a golden section on a line. (Collection of Robert Temple)

I have given all the background that is found in Euclid to establish a more primitive approach to what we call the "golden" section, "golden" angle, "golden" triangle, and so forth, than is usual. Euclid derived his information from the Pythagorean, Aristotelian, and Platonic geometers and systematized their findings in a brilliant manner. His personal affiliation was with the school of Aristotle, though the Platonists like to claim him because they don't want to let him get away. The Pythagoreans in turn got much of their geometrical knowledge from Egypt, which they freely admitted (Pythagoras lived there for some years, and after all, Euclid lived there for most or all of his life also), as well as from the Babylonian traditions. Looking at this from the point of view of Euclid in the fourth century BC, we are actually much closer to seeing it from the point of view of the earlier Egyptians themselves. Although it was the philosopher Thales of Miletus who was the first person to introduce Egyptian geometry to the Greeks, and he was earlier than Pythagoras, that is a detail people generally overlook, and we need not concern ourselves with it here.

So we see that the golden angle is really not so very difficult, and that the golden section that gives rise to it (when we form a triangle based on the golden section) can be obtained as easily as by drawing an overlapping square and a parallelogram! Therefore, let us not be intimidated by the fact that the golden angle has the bizarre value of 26° 33′ 54″, which seems so—well, so . . . very messy and disturbingly fractional. The Egyptians loved fractions, as they had no decimal system, and they could calculate fractions so fast it was like lightning. (It is a bit like how a Chinese person can calculate faster on an abacus than a Westerner can on an electronic calculator, if they are sitting side by side; I have done such

competitions in China myself!) I have dabbled a bit in Egyptian mathematics, and it is a wonderful parallel universe of its own, so strange, so fascinating. (For instance, they had no multiplication or division, as these processes were done instead by addition and subtraction in a very bizarre manner.) But because of the way they did things, fractions were perfectly acceptable to them and could be handled with the greatest of ease and fluency. Thus their manic fixation on the golden angle is not as strange as it seems to us, since its fractional nature was no problem to them.

Let me restate what the golden section is in another way as well. We cut a line at a certain point (the golden section point, which we have found either according to the method of Euclid or by one of the other ways), and that divides it into two shorter lines: one is long and one is short. The long one is called the major and the short one is called the minor. The ratio of the short line (minor) to the long line (major) is the same as the ratio of the long line (major) to the whole line before it was cut; hence the two ratios are what is called "proportional." And this proportion is known now as "the golden mean proportion," but was known to Euclid as "extreme and mean ratio." Leonardo da Vinci was obsessed with the golden section, or divine proportion, as he called it; his famous painting of the Last Supper, for instance, is based on its principles. The millions of people who have read the novel *The Da Vinci Code* will all be familiar with this. Few people realize that the golden section also entered music at the time of Monteverdi, and that Bach was so obsessed by it that he used it as the basis of the composition of all his fugues. Mozart also used the golden section in the composition of his music, as he was a great admirer of Bach. Anyone who wants to know more about that can go to our website, <a href="https://www.brancusiclassics.com">www.brancusiclassics.com</a>, and download the relevant papers by myself and my colleague the pianist and musicologist Stefano Greco.

It is worthwhile keeping firmly in mind that it is not only the ancient Egyptians who were maniacally obsessed with the golden mean proportion, but that such people as Leonardo da Vinci and J. S. Bach were as well. Indeed, so was the twentieth-century architect Le Corbusier, who embodied it in all his buildings just as if he were an ancient Egyptian. (And who can say, perhaps he was one.)

As mentioned briefly already, the golden section is connected with a series of numbers called the Fibonacci series (named after an Italian mathematician of the Renaissance called Leonardo Fibonacci, who discussed those numbers). I do not propose to give a full account of the Fibonacci series, or of Leonardo Fibonacci; that would be a distraction. All you need to know is that the series is a very simple one, where each number in the series is a sum of the two numbers that have gone before: 0, 1, 1, 2, 3, 5, 8, 13, 21, 34, 55, 89, . . . and so on (another name for this is a "summation series"). Know-it-alls of today think this is too complicated for ancient Egyptians. However, it has been conclusively proved by the Egyptian archaeologist Alexander Badawy that it was used in the construction of Egyptian temples throughout history. He studied more than fifty temples, took careful measurements, and published his findings in his brilliant book *Ancient Egyptian Architectural Design*. 46 Badawy is widely recognized as the leading authority on Egyptian architectural design and is also author of a work in three volumes, A History of Egyptian Architecture, which is the authoritative work in the field. (The information about the Fibonacci series is not to be found in those volumes, but only in his volume that is specially devoted to the subject, which appeared separately.) I have discussed his findings and especially their application to the temple of Seti I at Abydos in my lengthy account of our work and findings at that temple, which awaits future publication, so I shall not repeat any of it here. Suffice it to say that Badawy established conclusively that the Egyptians not only knew the Fibonacci series, which was based on the golden section (or, alternatively, the golden section derives from the number series, as it can work either way), but also that the Egyptians seem never to have built a temple without using it! Those who doubt me can turn directly to Badawy's book for the evidence that he compiled over many years of painstaking research in the field. It takes a long time to visit fifty monuments and measure them in detail, and he could do this only because he was an Egyptian, not just a visiting archaeologist from elsewhere.

I have not made a study of the possible use of the Fibonacci series at Giza. It was exhausting enough discovering all the golden angles and re-creating the forgotten design plan. I leave the Fibonacci aspects to others. I do not have enough time to spend weeks or months at Giza measuring everything the way Badawy did, nor would I be given permission to do so anyway under the present archaeological regime there.

In *Egyptian Dawn*, I carry the geometrical analysis of the Giza Plateau farther. In this book, I have attempted to restrict myself to aspects that have direct relevance to the Sphinx. In the next chapter, we take a "golden flight" into the realms of Egyptian mythology in order to try and group what all this obsession with golden angles was really about. The ancient Egyptians weren't just a lot of idle nerds doing all of this for fun. To them, it was a matter of life and death.

## THE GOLDEN ANGLE OF RESURRECTION

I explained at great length in *The Crystal Sun* that the brilliant Norwegian architectural historian Else Kielland (niece of the famous Norwegian painter Kitty Kielland) had proved conclusively in her book *Geometry in Egyptian Art*<sup>1</sup> that the golden section was mandated for use in every sacred building and every royal work of art throughout the whole of Egyptian history, even from as early as the First Dynasty. I cannot repeat that discussion here. However, I give one of many examples from her book of her minute analysis even of small royal objects, such as the painted casket from the tomb of Tutankhamun showing the king as a warrior in a chariot. My photo of this casket is in figure 8.1, and in figure 8.2 is a reproduction of Else Kielland's geometrical analysis of its design on the basis of multiple golden sections.

Golden angles, golden sections, golden triangles, and the Fibonacci series of numbers generated from the golden section permeated Egyptian culture for millennia and were a full-fledged priestly obsession for all those thousands of years.

So why did they have to use them all the time? Fine, we know that they *knew about* them, but why the compulsion always to use them?

This is where we enter the ancient Egyptian mind. There was no word for "religion" in the ancient Egyptian language, and also no word for "belief." They did not approach things the way we do at all. They did not have a sacred book in their hand and read from some text that told them how to think. They were not "people of the Book," which is how Christians, Muslims, and Jews are often described. Anyone wishing to understand the ancient Egyptian mentality needs to get as far away as possible from the mindsets of Christianity, Islam, and Judaism. The Egyptians were not doctrinaire, and they did not go to war over dogma. They would have thought the religious wars fought over the last two thousand years were insane, which of course they were. It is much easier to understand the Egyptians if you are familiar with Hinduism, Buddhism, or Taoism. Just as the Taoists' main idea is the tao (the Way) and the Buddhists' main idea is enlightenment through buddhi (the higher intuitive mind, which transcends the dichotomy of rational and irrational), so the Egyptians' main idea was Maāt, or Cosmic Order. The Egyptians wished always to follow Cosmic Order in the same way the Taoists wished to follow the Way. In both cases, the underlying idea was thought to be at the basis of the universal structure of everything. But whereas the Taoist Way was fluid and unstructured, the Egyptian Cosmic Order was highly structured and geometrical, so in that sense, the Egyptians and the Taoists were essentially the opposites of one another. Think of the difference between a young fellow in a T-shirt and a man in a dinner jacket: the first is like the Way and the second is like Cosmic Order. The Egyptians were highly formal. They were more interested in dress codes than the most exclusive American country clubs. Nothing casual was allowed. Furthermore, it was

all secret. The public was not admitted to the temples for the majority of ceremonies, for the simple reason that there was no "public" in any sense we would recognize today. The only people who were literate were the priests, scribes, and the royal family, and the royal family were all priests and priestesses anyway, as Egypt was a theocratric state. In the whole of Egypt, therefore, "culture" consisted of only a few thousand people at any one time, in addition to a few thousand more trainees and minor priests backing them up, who had some grasp of the lesser aspects of culture and a great deal of reverence. Everybody else living in Egypt consisted of "the people," who had culture imposed on them from the top down. Self-expression in art consisted of little tweaks here and there where an artist might show a bit of individuality in interpreting some rigidly perfect standard work according to a totally strict canon. What any individual thought or felt was considered to be of no consequence when matters of Cosmic Order were involved. No one, not even the pharaoh, was allowed to be an individuated person in the modern sense. Modern people did not exist, because they had not been invented yet.

Figure 8.1. This decorated chest was found in the tomb of Tutankhamun and is on view in the Egyptian Museum in Cairo. It shows the young Tutankhamun charging in his battle chariot and firing arrows at foes, which it is doubtful that he ever did. Such scenes were traditional for New Kingdom pharaohs, to whom smiting the enemy was part of the state pharaonic cult. Every pharaoh was meant to be the greatest and most fearless warrior in the world. Some pharaohs, such as Thutmosis III, really were ferocious warrior-pharaohs, but the teenaged Tutankhamun was certainly not in that category. There are multiple golden sections used in the construction of this dynamic and powerful design. The geometrical analysis of this image is shown in figure 21, which is taken from Else Kielland's brilliant book, *Geometry in Egyptian Art*. It was Kielland more than anyone else who comprehended the religio-philosophical depth and profundity of the golden section/golden angle obsession of the ancient Egyptians, and from whom I came to understand its true significance for the understanding of their culture. (*Photo by Robert Temple*)

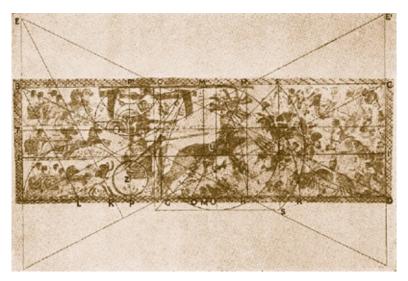

Figure 8.2. This is one of a set of five geometrical analyses by Else Kielland of the Tutankhamun chest in figure 8.1. Unfortunately, Kielland's book, which was published in 1955, has extremely poor-quality illustrations, so reproducing them is difficult. She points

out that both the vertical line *GG'*, which crosses the king's elbow, and the vertical line *HH'*, which goes through the horse's nostril and defines the front of its chest, divide the horizontal picture in golden section to the left and to the right. A ray shot down from *H'* at a golden angle strikes the baseline at *O* and makes a golden triangle. It is from point *U* on this line that one can draw two circles delineating the horse: the first, touching the bottom line of the strip (*AD*), contains the essentials of the horse, touching the top of its head and left foot, and the second and larger circle contains the whole of the horse, touching the top line of the strip (*BC*) and also the golden dividing line, *GG'*. From the top left corner of the strip, marked *B*, a ray shot down at a golden angle strikes the base of the picture at *L*, forming the golden triangle *ABL*. If you put your compass point on *L*, you can draw an arc that touches the center of the chariot wheel at Z. In the four analyses that follow in Kielland's book (which we cannot reproduce here), the unraveling of the geometrical basis of the design is completed, and various other golden angles are discovered within it. Kielland points out that all royal and sacred art was designed using rulers and compasses to exploit the golden angles, which determined the nature of a composition. There were usually multiple golden angles employed even in the smallest design, as a kind of golden spider's web, just as we find in the design for the Giza Plateau. It is clear that Egyptian architects, artists, and craftsmen working on the design of sacred or royal art or architecture were all trained to work like this. The purpose was to honor Maāt, Cosmic Order, and to imitate the sacred design of the cosmos, so that what was below would be the same as what was above.

People generally assume that the Egyptians had a bewildering array of gods. In fact, those gods were not as firmed up as, say, the Hindu gods. Egyptian gods could blend into one another and frequently did so. No god was safe from being co-opted to become part of another god. They were often as interchangeable as football players, but imagine football players exchanging arms and legs and jockstraps as well, and doing it all on the field in the middle of the game!

All those animal heads were symbolic in a more profound sense than we tend to think of symbolism today. Just because Thoth had the head of an ibis in most pictures, we must not assume for a moment that any Egyptian ever imagined that Thoth *really* had an ibis head. In this sense also, the Egyptians differed greatly from modern people. When Christians show pictures of angels with wings, they tend to believe that angels really do have wings. The first angels with wings were the Egyptian goddesses. I reproduce one in figure 8.3 as an example. No Egyptian truly believed that these goddesses really had wings, whereas many Christians truly believe that their angels do. That, then, gives you a feel for the difference in mental attitude.

Nothing could be further from the ancient Egyptian viewpoint. Doctrines varied as you went from city to city and temple to temple. The pharaoh could perform ceremonies in one tradition at one site and could perfectly happily perform different ceremonies in a different tradition at another site shortly afterward. No contradiction was seen in this, because the ossification of religious observance into a single form, fanatically adhered to without variation, was unknown at that time. Attitudes requiring monochrome belief are the psychotic perversions of later literal-minded and decadent cultures.

Figure 8.3. "An angel with wings" as portrayed by the ancient Egyptians, in this case Nut, goddess of the night sky. Over the past two thousand years, under the influence of doctrinaire "sacred texts," we have lost much of our capacity for symbolic thought and have developed unnatural habits of attempting to impose a ridiculous precision and specification on images that are meant to be merely suggestive. The Egyptians were not so stupid. The tradition of winged figures like this spread to the Greeks and was particularly prevalent among the Etruscans, thus influencing the Romans. It was from these sources that the highly conventionalized "angels" of Christianity derived.

It is necessary to be aware of this when considering the rich mythological lore, involving several apparently coexisting and even interpenetrating deities, which we will find connected with the goldenangle beliefs. At the same time, we must always keep in mind that beneath the fluid surface there was an immovable and invariant certainty: the all-encompassing Cosmic Order, which was the only thing that really mattered.

The Egyptians were very worried by death, more so than some other cultures. (Buddhists don't worry so much because they know they will be reincarnated.) Resurrection was therefore another of the Egyptians' manic fixations: everything revolved around this obsession. The body, which was called the *khāt*, had to be carefully mummified and preserved as an artifact, not because it would be resurrected itself, but because it acted as a focus for two of the spiritual aspects of the dead person that would survive death. If the *khāt* was interfered with, or if it was interred in a foreign land, this would cause serious trouble and destabilization. The "spiritual double" of the person, or his *ka*, survived, but needed to be near the *khāt*. The "spiritual force" of the person, called his *ba*, also had to come back and flit round the *khāt* from time to time. The *khāt* was thus both necessary and unnecessary at the same time, rather like one of those front rooms in an English working-class home that is never used by the occupants but is reserved for visitors who come once or twice a year.

The ba was depicted as a human-headed bird to indicate that it was always flying around and was not constrained by place. Gods could have more than one ba, but then they would, wouldn't they? The best thing that could happen to a person after death was to get lucky and become an  $\bar{a}kh$ , which meant a glorified spirit who survived in what we today might call heaven. Then you were really okay. But, of course, for that to happen to you, you first had to go to the netherworld and be judged and escape countless ambushing demons who wanted to destroy and annihilate you. So it was all very scary. The Egyptians had a far more nightmarish vision of what we call hell than we do. The terrible things that could happen to you there were beyond our modern imaginings. Another preoccupation of the Egyptians

was snakes. Snakes were everywhere. Of course, Egypt was and still is infested with cobras and sand vipers, both of which can kill quickly. It is hard to see a sand viper in the desert; you can step on one without noticing, and that is it. As for cobras, they always turn up just when they are not wanted, but they were especially hazardous in crypts and underground passages and hence troublesome to priests. It was natural for the Egyptians to think that if the surface of the earth was infested with snakes, the netherworld must be more so. After being decapitated, the evil dead then had the indignity of snakes crawling all over them in subterranean snakepits, and the snakes also chewed on them, just to add insult to injury.

There were friendly serpents, however, that were guardians in the netherworld. Presumably on the principle that it takes a snake to guard against a snake, friendly snakes were common because they were needed in such numbers. A massive snake called the Enveloper (Mehen) protected the sun god himself as he made his way through the netherworld every night. The Enveloper wrapped him up as tight as cellophane so he would be fresh in the morning. On the other hand, the most evil of all beings was a giant snake, called in Egyptian Apep and in Greek Apophis. He lived mostly in the netherworld, but he was also in the sky. It was his job to want to destroy everything, to wreck the boat of the sun god so that he could not rise in the morning, and to bring the entire cosmos to destruction. He was the ultimate enemy of Cosmic Order, and one had to struggle against him constantly. The equivalent of Apep in modern terms is Satan, or Samael, who is often thought to have serpentine aspects, specifically lower appendages in the form of snakes instead of legs.

There was, however, one genuine "snake with legs" that was plentiful in ancient Egypt, though it is bordering on extinction there now. I am referring to a North African skink, which is actually a lizard (family Scincidae). There are 1,200 types of skink in the world. But in the Menagerie of the Jardin des Plantes in Paris, Olivia and I were fascinated to observe the type that was once plentiful in Egypt. This type of skink looks so like a snake with legs, just as depicted on some of the Egyptian tomb walls, that Olivia suggested it was precisely what was being depicted in the tombs. (See figure 8.6 for an example.) We stood and watched these skinks for some time, and we noticed that they love to burrow in the sand, leaving only the tip of a tail sticking out. Since these skinks are tunneling creatures who burrow under the sand and stay there for long periods, they must have been seen as having a particular relevance to the netherworld and to the passages of the subterranean tombs constructed by the Egyptians. The Egyptians had not perfected the science of zoological classifications, so it is probable that they did not class skinks as lizards but instead as snakes-with-legs. And as such, the creatures would naturally have seemed to have the most special symbolic significance as denizens of the netherworld.

The third type of netherworld snake in Egyptian mythology is the symbolic snake. These were sometimes shown as the uraeus on the pharaoh's brow, or seen standing vertically on the tips of their tails, like ballet dancers en point. The vertical ones are often called Nehep snakes, from the verb meaning to leap up, which was a euphemism for resurrection, since resurrection was always associated in the Egyptian mind with the leaping of the resurrected sun over the horizon every dawn. These Nehep snakes are common in the netherworld depictions. Figure 8.27 shows one in a crypt of Denderah. It was not imagined that Nehep snakes existed any more than unicorns do, but they were very useful to get ideas across. Nehep also means to leap up early (or get up early, as we would say) to adore the rising sun. Strangely, the Nehep serpent seems somehow to have survived as a motif into the Middle Ages, when it was adopted as the crest of a princely Hungarian family named Bethlen (see figure 8.7, a photo Olivia took of this crest carved in stone at their castle in Transylvania).

Now we come to the main mythological motif connected with the golden angles at Giza. Not surprisingly, it was a resurrection motif. Many people are familiar with the giant woman arching over

certain scenes in Egyptian art, named Nut, who was the goddess of the night sky. She had stars along her body. She swallowed the sun into her mouth every night, and he emerged from her vagina every morning (see figure 8.8). The Egyptians were not shy about discussing and depicting the genital organs and did not consider them rude or shameful; they were rather inclined to flaunt them. Concepts of Puritanism were as alien to the ancient Egyptians as air is to the moon.

Figure 8.4. The mummiform Osiris in his netherworld shrine and the Earth god Geb at right and the netherworld god Sokar (Sokaris) at left are all jointly rising at the horizon, while over them is held by two solar *ba*-spirits the stretched-out length of the evil serpent Apophis, enemy of the sun, whose head has just been severed by a knife. By the slaying of Apophis, victory and resurrection have been achieved, as the sun rises, with the dead Osiris shortly to become transformed into the living Horus. This is figure 127 on page 375 of vol. I, Alexandre Piankoff and N. Rambova, *The Tomb of Ramesses VI*, Bollingen Series vol. XL:1 (New York: Pantheon Books, 1954), 2 vols.

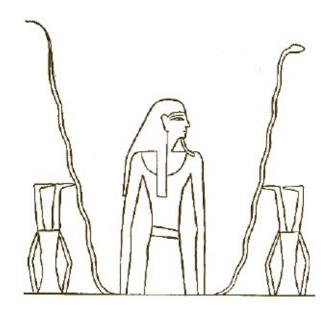

Figure 8.5. Here we see yet another view of the giant Osiris rising at the horizon from the netherworld. He is emerging from the coils of the evil serpent Apophis (the Coiled One), showing that life and resurrection are again made possible despite the attempt of Apophis to prevent them. (Apophis was the Egyptian equivalent of Satan.) The two upside-down figures are each called "the gory one" and represent the decapitated spirits of the evil dead who are in the process of being annihilated in the netherworld. This is figure 27 on page 130 of vol.1, Alexandre Piankoff and N. Rambova, *The Tomb of Ramesses VI*, Bollingen Series vol. XL, 1 (New York: Pantheon Books, 1954), 2 vols.

Figure 8.6. The goddess Neith, wearing the red Crown of the North, stands at left, apparently signifying a northern entrance to a secret passage into the netherworld. The descending passage, which is probably meant to represent the entrance to a pyramid, commences directly over her head. A sarcophagus is depicted as sliding down the passage, though it is shown above the passage so as not to suggest a permanent blockage. (The Egyptians often did this kind of wonky depiction, as perspective realism was not the intention in mythological drawings. Lakes, for instance, were always drawn in plan as if looking down on them from above, even though the figures beside them might be shown in profile as if we were standing beside them. Egyptian sacred art was always a many-viewed totality, and what was being portrayed was never shown only from a single observer's perspective point. The psychology was that the observer was not considered important, which is the precise opposite of the modern Western attitude, which regards the observer as all-important.) This wall painting is in the tomb of Rameses III in the Valley of the Kings, and it has apparently never been reproduced or even discussed before. Such paintings, although of New Kingdom date, derive from images found on old papyri that date from many centuries earlier. Many visual and even textual references to Giza (by this time a largely abandoned necropolis) survive in these New Kingdom pictures, owing to the conservatism of the Egyptian priests and despite the fact that they may have ceased to realize their origin and their original significance. Neith is speaking in a friendly fashion to an enormous netherworld serpent with human legs and a human head, who has a goatee and a skullcap. This is not one of the dangerous and evil serpents of the underworld, such as the horrible demon Apep, but a friendly one who takes his name from the Egyptian word tep, which means head. He is called Tepi-sau-medjen, which means "he with a head who guards the way." We can call him Tepi for short. Tepi was a particularly helpful chap to have around because, like many of the benign netherworld denizens, he emitted light, which made it easier to see in the dark passages. This painting in the tomb of Rameses III is a scene from The Book of the Hidden Chamber, showing the entrance to the netherworld at Rostau (Giza). It is possible that the artists who painted this in the tomb near Thebes had never seen Giza and had not the slightest idea what was being referred to in the images. The passage in this painting has the number three written in it, and the same number appears beneath Tepi's chin. Neith was an extremely ancient Egyptian deity whose importance goes back to predynastic times. She was said to weave the shrouds for the dead and to protect them. (Photo by Robert Temple)

Figure 8.7. This is the heraldic crest of the Hungarian princely family of Bethlen. This particular plaque was erected in the seventeenth century by Prince Alexius de Bethlen at his Transylvanian castle at Kreisch (now called Kris in Romanian). The ancient Egyptian Nehep serpent symbolizing resurrection, the serpent standing on its tail and springing into eternal life, has

somehow survived here, having been adopted in the Middle Ages as a family symbol by the Bethlens. In this instance the serpent wears a crown and holds in its mouth an orb surmounted by a cross, symbolizing holy power. Probably this motif survived from antiquity through secret organizations such as the Freemasons. The Bethlens recently reclaimed this half-ruined castle from the Romanian government in restitution for its illegal seizure from them in 1947 by the Communist regime. Unfortunately, the vast library of priceless old books that had been accumulated in this castle for centuries was taken out into the courtyard and burned by the fanatical commissars as decadent bourgeois literature, and not a single volume survived. (*Photo by Olivia Temple*)

Few people realize, however, that Nut was not the only giant figure in Egyptian mythological art. In figures 8.9 and 8.16 to 8.19, we see the giant male deity who was depicted only in netherworld scenes. He was Osiris rising as the sun god Re (also sometimes spelled Ra) at the horizon every morning. He had to be huge, because his feet reached all the way down into the very bottom of the netherworld, while as he rose above the horizon, his arms touched the sky. The most interesting and informative study of this giant deity is a book written by John Darnell of Yale and published in 2004 with the rather lengthy title of *The Enigmatic Netherworld Books of the Solar-Osirian Unity.* It is a huge book of 640 pages and is not light reading. It has a price nearly as large as the title. The author also occasionally lapses into German (you have to know that Normalschrift means noncryptographic, etc.). Much of it is written for specialists, consisting of lengthy analyses of the cryptographic inscriptions in tombs (because he has to justify to his colleagues his choices of translation), and also the inscriptions on the Second Shrine of beaten gold found in the tomb of Tutankhamun. Anyone who really wants to know about these things needs Darnell's book, and a great deal of time. Because it is inadequately indexed, I found myself forced to memorize rather more of it than I wanted to, because there was no way to refer to many things in it otherwise, as I rarely write notes when I do research. I found it necessary to read Darnell's book many times, because the material is so utterly bizarre that you just have to keep reading it until the bewilderment vanishes. It is like getting used to drinking retsina; you just have to keep at it, and then you like it.

Figure 8.8. Detail of a painting of the goddess Nut, goddess of the night sky, as portrayed in the tomb of Rameses IX in the Valley of the Kings. (*Photo by Robert Temple*)

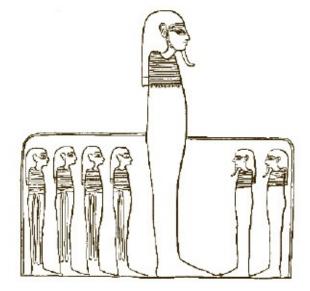

Figure 8.9. The giant figure of Ra-Osiris rising from the horizon is here "showing his body" as he rises, having burst forth from the restricted space of the netherworld, where the bodies of the blessed dead are found. The text says of them: "These souls pass after him while their bodies remain in the mounds." This is figure 88 on page 328 of vol. 1 of Alexandre Piankoff and N. Rambova's *The Tomb of Ramesses VI*, Bollingen Series 40:1 (New York: Pantheon Books, 1954), 2 vols.

I would have thought it more elegant to call the giant deity "Osiris as the Sun," but Darnell wants to call him Re-Osiris, so who am I to disagree? It is less clumsy than "the Solar-Osirian Unity," a name he also uses. The symbolism is very thick here and involves multiple gods all merging, so you need to keep your head. Explaining what is going on can almost read like a cast list at the theater. First, there is Re, and that is the name of the sun in general, and especially of the daytime sun, whereas his other names are of his specific aspects. For instance, when he is rising, Re is also called Khepri (also sometimes spelled Khepera), which is the name of the scarab beetle, or dung beetle. The symbolism of this is that real dung beetles push spherical balls of dung larger than themselves for long distances over the desert floor. So the Egyptians thought it would be appropriate to adopt this as the symbol of the sun being pushed up over the horizon at dawn. No one imagined that there really was a giant dung beetle doing this; it was all symbolic. In speaking of this, one could also call the sun Re-Khepri, which was another way of saying "the rising sun." In the various depictions in figures 8.10, 8.12, 8.17, 8.37, 8.43, and 8.45, there are Khepri beetles beside the solar disk, and this is what they mean. The setting sun was an aspect of Re called Atum, which was the name of the creator god. Hence the sun was often called Khepri-Re-Atum. That may sound like three gods in one, and it is. But let's not get into arguments about the nature of the Holy Trinity.

As if that weren't enough suns, we also have Osiris as the sun and his son Horus as the sun. In addition, we have not just one *ba* of the sun, but several. The main *ba* of the sun was depicted as a man with a ram's head standing in the middle of the solar disk. But the sun could have extra *bas* when he needed them. As they represented emanations of the solar force, it is understandable that he did not have to be restricted to one. He also had an eye that roamed around, two eyes that did not roam around but simply gazed, and so forth. But there is no need for us to examine all the things the sun could do: for us, his journey at night and his rising are enough.

What concerns us at Giza are specifically the solar connections of Osiris and Horus. In a sense, Osiris was the netherworld aspect of Re, as he was always represented as a mummy who was king of the netherworld, and so in a sense, when he entered the netherworld, the sun became identified with Osiris in a spiritual manner. Gods are such highly advanced beings that they can become one another sometimes without worrying about it. Then they can separate again with no hard feelings. All this could even take place without the need for sex.

One might wonder how and why the sun would want to become spiritually united with a boring, smelly old mummy. To the Egyptians, however, all important mummies could be revivified. Although one's physical body had to stay behind, the *ba* of one's mummy could be awakened, could fly forth and follow the sun as a member of the divine entourage. In this sense, the Egyptians claimed in their mythological writings that the "deserving dead" were revived and brought back to life by streams of solar light shooting at their foreheads or into their mouths. The sun "spoke light" (in the tomb of Rameses VI we find the statement about the sun that "his speech is light"),<sup>4</sup> and the sun's "word" (an idea that the later Greeks borrowed in their concept of the *Logos*, "the Word," which also passed into Christianity through Egyptian Gnosticism and Neoplatonism) brought resurrection to the dead. See figures 8.38 to 8.41.

So a parallel myth to that of Khepri-Re was the myth of Re-Osiris, and in a sense they were the same, so much so that Khepri was always shown preceding Re-Osiris in the netherworld drawings. We have to keep in mind that gods were not exclusive as far as the Egyptians were concerned, and were not necessarily real either. It would be more correct to say that Khepri was a motive force than that he was any kind of actual god. Khepri was not offended at being relegated to the status of a visual aid, because he did not exist anyway. He was only a pretty picture (if you like beetles).

That leaves us with Re-Osiris. What was he/were they? Here the symbolism gets really thick. The concept of the golden angle becomes part of the symbolism too, although that has not been recognized before. It will become clear to us that the golden angle was viewed by the Egyptians as symbolizing resurrection, and that it represented the transformation of the dead Osiris into his living son Horus in the person of the rising sun. Once we understand that, we can begin to comprehend why Giza was a mass of golden angles. As the ultimate necropolis of the Egyptians, it was important that it be magically replete with the power of resurrection conferred on it by having an invisible pattern on the sand of the resurrection angle endlessly repeated, like a mystical chant that never ends. And the Sphinx was fundamental to this, for as the guardian and watchdog of the necropolis, protecting entry to this magical land of the West, Anubis faced due east and every morning viewed the recurrence of the miraculous phenomenon that the Egyptians called Horus-in-the-Horizon. The most important occasions were, of course, the spring equinox and the autumn equinox, for on those days, the sun rose precisely at the center of the horizon and looked the Sphinx directly in the eyes (both when he was Anubis and when he later became Amenemhet II, for both of them have two eyes, whatever else they may not have in common).

What was Horus-in-the-Horizon? It sounds impressive, but was it anything but words? The Egyptian priests were eminently practical people, and they worked out a very precise mythological symbolism and explanation that tied together many of their preconceptions and expressed everything. To understand it, one has to understand their magico-symbolic mode of thought. Just as they might intone prayers every morning to a beetle in the sky without believing there really was a beetle in the sky, they envisaged this giant being standing in the horizon with his feet in hell and his head in heaven and called him Re-Osiris, or Khepri-Re-Atum, or whatever you like. They were not literal-minded. Today, in a culture stripped bare of all magic and symbolism other than that which represents money (a yacht is now a symbol, and so is a Rolex watch), it is difficult for us to imagine how Egyptian priests thought. They did not want to get rich, because there was nothing they could buy. But they did want to live forever. So their priorities were different from ours. They were also fearful that if they became evil, they would not survive, because they were convinced that the evil dead met with the most horrible of fates, culminating in annihilation. They were careful to preserve their purity by washing themselves fastidiously every morning, observing endless ceremonies, washing their statues daily, singing hymns, and generally being good boys. They were always up before dawn because it was a necessary act of politeness and respect for them to welcome the

sun's return. They were like butlers greeting the master when he returns home. They avoided various foods that might be taboo, such as certain fish. And among the other things they pursued with the same manic obsession was sacred geometry. It had to be embodied in everything that was sacred. Otherwise, the magic might be lost, a terrible sacrilege might be committed, and Cosmic Order might be defied, which would bring retribution. "Just to be on the safe side," they might say, "we had better add a few more golden angles." So there could never be too many. And Giza is the proof of that mentality.

Now we come to the rising sun as expressed in both mythology and geometry at the same time. If we look at and figures 8.11 to 8.13, which show the same scene, we see one of the most famous of the "leaning pharaohs" in Egyptian art. This is a picture of the deceased pharaoh Rameses IX, who has "become Osiris." All pharaohs when they died "become Osiris" simply by the process of mummification. It was what all the ancient texts said: "He has become Osiris." But since *every* pharaoh was an Osiris, there were rather a lot of Osirises, and it is only in the mode of symbolic thought that you can avoid the clutter of having a lot of look-alikes wandering around the netherworld all claiming to be the same god and getting into fights with one another. Once again, we must realize that the Egyptians did not *really* believe that each pharaoh "[became] Osiris"; what they believed was that each pharaoh became *an* Osiris. This was a symbolic expression. Christians who take communion and eat the bread and drink the wine "partake of Christ" and become one with him. Or at least, that is how they express it. Christians do not take "being one with Christ" literally in the sense that they have *become* Christ; they mean it symbolically and also in the sense of *mystical participation*. Being "one with Christ" is a bit like falling in love: you remain yourself, but you "become one" with the beloved. Similarly, the dead pharaoh "become[s] one with Osiris." I hope that explains it sufficiently.

Now to return to Rameses IX, who has become *an* Osiris. There he is, raising his arms and stretching himself out at a peculiar angle. This drawing occurs on what is called the Enigmatic Wall in his tomb in the Valley of the Kings, on the right as you go down. The entire wall contains strange drawings relating to the netherworld and texts that are written in cryptography. Anyone who was above the rank of junior priest could read cryptographic hieroglyphics, and it may be that the chief reason for using them was to conceal the true meaning of the inscriptions from the tomb painters, who had not been initiated and were not worthy to read what they were painting. In Egyptian cryptography, every sign means something other than what it normally means. Not all cryptography has been deciphered by modern scholars (and there are a few instances of a super-cryptography that cannot be cracked), and they are still arguing about it. However, in most cases, the texts can be read with tolerable reliability. Naturally, the number of people in the world who can actually do this today is remarkably small. You don't get your yachts and Rolexes that way, although in a just and philosophical world, the tycoons would have to hand over their yachts and Rolexes to the people who can read ancient texts, which is more difficult than making money.

The angular pharaoh Rameses IX is a drawing I have already reproduced and discussed in *The Crystal Sun*. But at that time, I carried the discussion only so far. I explained that he was at the golden angle. But now we have to consider what it means for a pharaoh to be at a golden angle, for that is fundamental to an understanding of Giza. This will also bring us to the strange subject of Christ on the cross.

The golden angle occurs at the top of the triangle formed by the leaning pharaoh. The vertical line is in this case the base of a triangle and the pharaoh is the hypotenuse. (A hypotenuse is a right-angled triangle's longest side, which is opposite the right angle.) That is why I call such figures, of which there are many in Egyptian tomb paintings and papyri, "hypotenusal pharaohs" or "hypotenusal Osirises." Such figures are always hypotenuses of triangles (and if drawn correctly, of golden triangles), even if the other

lines are not drawn. In this case, however, the other lines are very clearly drawn. And in the drawing of Rameses IX, just to emphasize the true meaning, the other two sides of the golden triangle are inhabited also by a friendly Nehep (sometimes called Neheher) snake, who, as I explained earlier, symbolizes resurrection. This pharaoh, like all hypotenusal pharaohs, is in the process of being resurrected. If you ever die and want to come back to life, it is very easy. All you have to do is become a hypotenuse.

Another feature of Rameses as a hypotenuse is that he is what is called ithyphallic, that is, he had an erect phallus. It has been largely rubbed out by prudish Victorians, or Copts, or Muslims, or whatever. Many of the phalluses have been hacked off the images in Egyptian temples and tombs because of the hypocrisy of most human societies, which prefer to ignore the existence of the genitals in public while overindulging them in private. So today's computer hackers were once preceded by avid penis hackers.

The Egyptians were very happy incorporating penises and vaginas into their sacred art. They would not have draped a loincloth over the crucified Christ. People of high symbolic rank are often assumed to have transcended the material requirements of ordinary life and not to have genitals, for instance. But as I have already said, the Egyptians were immensely practical. Perhaps they did not need to disguise physical details because they already had enough symbols as it was, without transforming the body into one by stripping it of its genitals.

The obvious procreative power of the erect phallus was a symbol to the Egyptians not only of fecundity, but also of creation itself, and, consequently, of resurrection. If you are a dead pharaoh and you are turning into a hypotenuse, it is only natural that you should get so excited that you have an erection.

Rameses IX was a rather late pharaoh, as the New Kingdom in Egypt was drawing to its close. So his artists got it a bit wrong. They knew he had to be portrayed as a hypotenuse, and that the golden angle must be used, but they put the golden angle at his hands, whereas it is really meant to be at his feet. They had lost the plot by this late period. As we see in our other illustrations, the whole point is that the golden angle generates the image, and it occurs at the feet. As time went on and the traditions were grasped less adequately, many of the priests became alarmed. There is a pathetic hieroglyphic inscription from Roman times, when things really were coming to an end finally and completely, where a priest says in his funerary testament, in desperation: "Set your hearts on what is therein [the texts of the stele]; do not forget the text collection; make copies of it; adhere perfectly to the text." <sup>5</sup>

Darnell quotes this sad example of what happens when things fall apart and the young priests don't listen any more. However, even though things were a bit wonky in the design, the picture in the tomb of Rameses IX is very striking. Notice that the beetle Khepri is practically crawling up the pharaoh's nose. This is to remind us that we are talking about the rising sun here, just in case anybody was inclined to forget. Unfortunately, this magnificent image is now behind glass with some rails in the way as well, so a decent photograph has now become impossible. I reproduce my photo through the glass in figure 8.11, which is inadequate, but one cannot really do much better than that nowadays. At the same time, I reproduce an old black-and-white photo from earlier and happier days as figure 8.12.

Figure 8.10. A highly aroused hypotenusal Osiris depicted on the Papyrus of Heruben B. We see here the deceased Osiris as a hypotenuse, and directly over his erect phallus we see the beetle Khepri and the globe of the sun, indicating the rising sun, which rises and is reborn from the power of Osiris's fecundity, which is his power of resurrection. A protective Mehen serpent (the Enveloper) constitutes the base and altitude of this triangle, which is crudely drawn. The triangle itself is filled with sand, suggesting the sandy region of the netherworld, which is a reference to Giza. The coded reference of the triangle being on the sand is a way of indicating the many golden triangles "on the sand" that constitute the Giza Golden Plan, though whether this was still consciously understood by the time this papyrus was painted just after the time of the New Kingdom is doubtful. The Papyrus of Heruben B, in the Egyptian Museum in Cairo, is the second of two papyri that once belonged to the Chantress of Amon-Re, Heruben (Resplendent Sky), granddaughter of King Menkheperre of the Twenty-first Dynasty (tenth century BC). A line joining the tip of the penis with the tip of the nose makes a golden angle with the horizontal, as does a line joining the tip of the toe with the bend in the serpent's neck, which is the top of the triangle's altitude. This is a detail from plate 2, a folding plate in volume 2 of *Mythological Papyri: Egyptian Texts and Representations* by Alexandre Piankoff and N. Rambova, Bollingen Series XL:3 (New York: Pantheon Books, 1957).

Because the drawings beside Rameses IX as a hypotenusal pharaoh are so bizarre, I feel that I must take a moment to explain them; otherwise, everyone will be frustrated. I must also repeat what the texts that accompany the pictures say. The cryptographic inscription that goes with the hypotenusal pharaoh states: "This god [Osiris, or Rameses IX as Osiris] is in this fashion: his arm in the height, his feet in the place of destruction." <sup>6</sup>

Figure 8.11. A photo of the hypotenusal pharaoh in the tomb of King RamesesIX. His erect phallus has been chipped away. The image is now behind glass and impossible to photograph properly. (*Photo by Robert Temple*)

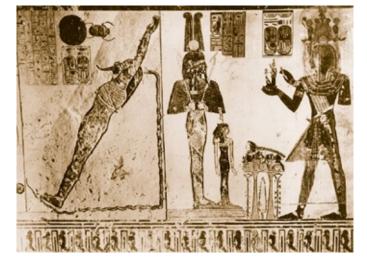

Figure 8.12. A hypotenusal pharaoh, in this instance, Pharaoh Rameses IX, as portrayed in his tomb in the Valley of the Kings, on the right of the descending passage as you go down. (The painting is now behind glass and partially obscured, so adequate photography is no longer possible.) The mummified pharaoh, who has "become a Horus," forms the hypotenuse (called Horus by the Egyptians, according to Plutarch) of a golden triangle. The golden angle is formed by the vertical and a line that runs from his hand to the back of the pharaoh's heel. In figure 8.37 is another hypotenusal pharaoh preserved in a papyrus, where the golden angle goes the other way, with no arms outstretched and running from his heel to the center of his head. Since the "pharaoh as a Horus," that is, the pharaoh as a hypotenuse, is purely symbolic, it doesn't matter whether the golden angle runs down from his head or up from his feet.

It is a standard formula in all these types of inscriptions to begin by saying "This god/these gods is/are in this fashion . . ." Here, because the text from a papyrus has been correctly copied by the scribes, the description is accurate. Even though the golden angle has been put at the wrong end of the figure, the textual description has the feet in the right place and the arms in the right place. By "the place of destruction" is meant the lowest depths of hell where the evil dead are annihilated, also known as the Place of Annihilation. As Darnell has probably been the first person to observe since antiquity, the Place of Annihilation or Place of Destruction was conceived of as being far below the eastern horizon. (This was necessitated by the fact that Re-Osiris had to have his feet there when he was rising.) And as you may be guessing by now, the hypotenusal pharaoh was meant to be identified with the giant Re-Osiris at the eastern horizon as the sun rises. So, although he was often depicted as a giant standing at the horizon with his feet in the depths of hell, doubtless squashing a lot of the evil dead in the process, the rising Re-Osiris was also represented as a hypotenusal Osiris, or, as Darnell likes to call it, an Osiride figure. In fact, Darnell calls the hypotenusal Rameses IX an Osiride figure, which indeed he is. One way to understand what the scholars are saying is to figure out the terms they use, so one knows what they are referring to. Half the difficulty with scholarly books is that confusing terminology is used, so that ordinary people get lost and cannot follow the argument. As for Egyptological books, they are as incomprehensible to ordinary readers as books on the calculus, due to the fact that they are full of linguistic symbols that spell out the Egyptian words without vowels. These symbols achieve precision and impress fellow scholars, but they exclude readers who are not also Egyptologists, unless they are prepared to learn these symbols. By definition, therefore, Egyptologists are only writing for each other. Since the views of the public do not matter to them, as they are generally interested only in their professional and academic lives, positions, and reputations, they don't care. Thus it is that the public is rarely kept informed, unless an Egyptologist deigns to write a popular book now and then. I have made a point of never using any of those symbols in this book, and sometimes when quoting I have transcribed them into comprehensible familiar letters for the benefit of the reader.

The entire base of the Enigmatic Wall of Rameses IX consists of a row of bound enemies kneeling, with their arms tied behind their backs like prisoners taken in battle. These represent the defeated evil

dead, "alluding to the time of the final victory of the sun at the end of the night as the time of the flaming destruction of the damned," as Darnell colorfully expresses it. $^{7}$ 

The top row of drawings on the Enigmatic row consists of eight circles. The first four are yellow and the second four are red (this cannot be seen in the blackand-white figure 8.13, and there is no color image of the full Enigmatic Wall). They all contain inverted figures of men with their arms and legs spread wide. Solar or stellar disks rest beneath each, indicating their attributes. Darnell believes that the circles represent sources of light, but although the discs containing the men are made of light, they are not emitting light, thus giving the inverted figures a "clothing effect of light," for he says: "Light travels around and hides these figures." Darnell says these plummeting beings are falling stars, "lords of the Netherworld" (nebu Duat), "stellar Blessed Dead." (There may also be an implied reference to meteorites, the sacred aspect of which to the Egyptians I discussed at very great length in *The Crystal Sun*. The iron that fell from heaven, often magnetic lodestone, was carefully gathered from the sands of the desert, where it can easily be seen as black stones on the yellow sand, and used for sacred purposes that I have described.) The reason why they are upside down is that everybody who enters the netherworld does so upside down. Part of the struggle in the netherworld is to turn yourself right way up and not remain inverted. The evil dead remain upside down and then have their heads permanently cut off as well. (I say "permanently cut off "because the "justified dead" had their heads handed back to them after their judgment in the netherworld, and the heads were stitched back on for them by Anubis! How many people have dogs like that, who are good with needle and thread?)

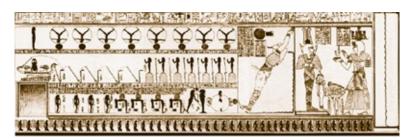

Figure 8.13. This is a drawing of the entire Enigmatic Wall found in the tomb of King Rameses IX in the Valley of the Kings, on the right as you descend into the tomb. The hypotenusal pharaoh in the right third of the wall design is the same as seen in figures 8.11 and 8.12. This image of the whole wall comes from an article by Felix Guilmant, "La Tombeau de Rameses IX" ("The Tomb of Rameses IX"), in *Mémoires de l'Institut Français d'Archéologie Orientale*, Cairo, Volume 15, 1907, p. 63. It is not necessary to comment here on the iconography and importance of this Enigmatic Wall, as the design of the wall and the significance of its elements are analysed in extensive detail in several pages of the main text, commencing on page 400.

One of the strange features of the Great Pyramid is that the Subterranean Chamber beneath it has a smooth ceiling resembling a floor, but the actual floor itself is rough and bumpy and difficult to walk on without twisting an ankle. If the Subterranean Chamber is taken as representing the netherworld, then of course it would have a smooth ceiling resembling a floor, because the dead are upside down and have to walk on the ceiling.

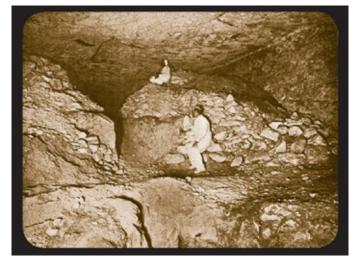

Figure 8.14. According to ancient Egyptian theology, the dead enter the Other World upside down, as mirror images of themselves on earth. They therefore walk on the ceiling. This photo shows the bizarre Subterranean Chamber beneath the Great Pyramid. No one has ever understood why it has a smooth and flat ceiling, meticulously cut out of the bedrock to be level, but a rough and lumpy floor. The reason is presumably because it represented the netherworld, and the dead entered it upside down, walking on the flat ceiling, and the floor did not matter. We should always remember that the dead also walk on the ceilings of descending passages in Egyptian pyramids and tombs, and we should be alert to signs and indications above our heads, not below our heads, in such passages. (An example is the "black door" in the ceiling of the Descending Passage of the Great Pyramid, seen in figures 7.12 and 7.13, which, although obscured originally to the human eye by a limestone slab, would not have been invisible to the dead, who can see through matter. A "black door" of basalt was, I believe, often meant to be a secret sign for the dead. Figure 7.15 is a photo of an odd basalt stone in the Valley Temple, for instance, which certainly has mysterious significance of some kind and is definitely not accidental.) This photo was taken in 1909 and shows John Edgar in the center of the photo. Crouching above him is his Egyptian assistant, Judah. All the loose rubble we see here has since been removed, but the floor today remains as lumpy and rough as ever. (This photo is Plate LIII on page 148 of John and Morton Edgar's book, *The Great Pyramid Passages and Chambers*, Glasgow, 1910.)

Beneath the plummeting stellar beings is, first of all at far left, the sun god as Khepri in his boat, with one of the Eyes of Re on either side of the beetle. He is sailing through the netherworld, with difficulty, trying to avoid getting grounded on the back of the evil satanic serpent Apep, who is shown writhing in his coils beneath the boat. The cryptographic text says: "In this manner does this god travel in his boat, having navigated upon the back of Apep. As soon as he passes by, they loose their arrows. While casting this fire, those on their mounds leap up to (or 'for') him. Those armed with their arrows burn up the enemies of Re, even when he passes by them."

Just to the right of the solar boat, arrows may be seen making golden angles with standing serpents. Darnell thinks these arrows are being fired at the serpents to kill them, but a closer examination of the picture reveals that except for the first, the feathered ends of the arrows are beside the serpents, and the tips are pointing away from them, with dotted lines showing their trajectories from the tail of one to the head of another. These arrows are meant to represent flaming light rays that "cast fire" and "burn up the enemies of Re," but the exact interpretation of the scene is elusive. In Egyptian mythology, however, it was not necessary to have a bow to fire an arrow. Certain netherworld messengers were reputed to shoot fiery arrows directly from their mouths. To their right are seven slaughtering places where evil serpents, enemies of Re, are destroyed. These are slaughtering places represented as mounds of sand. As the text continues: "In this fashion do they exist: the Nehaher snakes which are slaughtered, he making a pause at their slaughtering pit of sand; 'He who hides the mystery, who praises the members which are in it (the shetau)." 10

Sometimes Nehaher serpents are friendly, but in this text, they are enemies of Re, and Apep himself is called Nehaher. The erect serpents in front of the mounds of sand, on which female executioners stand, have arrows of flaming light penetrating their heads and killing them. These executioners, who are not

shown actually firing arrows, are in a posture of adoring the sun while they carry out their job; they are all called *petekhi*, which means "those who lay low the enemy." Although they appear feminine, Darnell believes they are essentially androgynous. Each mound is called an *iat* mound, and is a *shetat* (mysterious place). The Shetayet is the portion of the netherworld through which the sun moves at night, and is described as mysterious. The name is related to the Egyptian adjective *sheta*, which means hidden.) Two of the arrows flying at the serpents have actually been fired from the solar boat. Darnell points out that in Egyptian, the verb *seti* has two meanings, casting light and firing arrows, and he gives an example from *The Book of the Dead* where a conscious pun on this double meaning occurs. Therefore the firing of arrows in the drawings, either by the sun or on behalf of the sun, really means the shooting of flaming light rays, and the arrows are symbolic of that.

There is a further inscription about this register of the drawing, which says: "In this fashion are they in the Place of Destruction: This god [the sun] calls out to them, that they should be high [leap up] for him, they being endowed with their *kheperu* [beetlelike] manifestations. When this god goes to rest, his disk is in this cavern, and his birth occurs therein. After this great god passes by these goddesses, they stand up; then the complete darkness covers them." 14

In the third horizontal register, below the serpents and arrows, we have at left what appears to be an empty hidden chamber. Ancient temples tended to have such chambers.

To the right of the hidden chamber, there are four standing goddesses enveloped by protective serpents. Their names are given as "Mother," "she relating to the sarcophagus," "she relating to the Temem Shrine," and "Milk." Each serpent is of a different type, with a different name as well. Farther to the right are four bending figures bearing solar disks on their chests, who are named "The protective one," "(no name given)," "The naked one," and "The pleased one." A text describes this group as follows: "Oh these you four gods who are over these two sides of the sky." 15 Darnell points out that they are hermaphrodites, because although they have names written in the feminine form (and also long hair), they also have phalluses and are ejaculating. In front of each of these bending figures sits a small child, all having the same name: He of the flame. These children represent youthful forms of the rising sun, according to Darnell. And he describes these figures thus: "Each bending, ejaculating figure with a flaming (?) child before it . . . the name of the solar child . . . [could be translated as] the newborn sun." 16 He adds, "The child, the flame, and punishment are all in keeping with a representation of [re-creation] and the eastern horizon, where the sun is reborn, and the damned received their ultimate fiery punishment. The androgynous, bending figures both ejaculate and spit, dots of flame issuing from their mouths and pudenda. These spewing effluvia are a pictorial pun on the verbs *nekh* and *nekhekh*, 'spit' and 'ejaculate' and depict the spitting and ejaculation at creation." (The creator god, when he created the universe from his seed, did so not only by spewing his seed from his erect phallus by means of masturbation, but also by "spitting." "Spitting" was an Egyptian punning euphemism for ejaculating.)

Darnell continues his evocative description:

The spittle of the figures pours down to the left of the figures' heads; in three of the four groups it strikes the ground just to the left of the heads of the scarabs that lie horizontally beneath the bent backs of the figures. In the second group to the left, however, the spittle bends in towards the head of the scarab, an indication that the scarab results from the spittle of the bending figure. In each group the dots of ejaculate flow down to the top of the child's head, an indication that the child results from the semen of the bending figures. . . . The *kheperu*-form of the sun is spat out, and the *mesut*-form is ejaculated. The fiery effluvia of the entities bring forth the sun, and the ejaculate suggests the

overflow of Nun [the cosmic ocean], in which the sun is born. 18

Next, beyond the bending figures, we have a bearded figure leaning forward at a golden angle and presumably being a miniature version of the hypotenusal Osiride pharaoh, though this time facing inward rather than outward. He is holding an upright serpent, who is labeled a Nāu serpent. This is a sacred snake, representing the primeval creative forces, who can lead the dead up to heaven by bringing about a repetition of creation, according to Darnell. Emerging from the head or mouth of the Nāu serpent is a Khepri beetle, symbolizing the birth of the sun. Beneath the Nāu serpent is another flaming child representing the rising sun. Darnell believes that the two sets of four entities in this register refer to the four cardinal points and the four winds, which combine to enable Re to sail in a fair wind toward his rising. Darnell makes no comment regarding the two-faced standing entity who comes next and seems to be female on the left and male on the right. Perhaps this figure is meant to suggest the rising and setting of the sun, or just someone who cannot make up his or her mind. The final drawing in this register is a large solar disk preceded and followed by a Khepri beetle, indicating the solar rising. Inside the disk is a woman. Darnell says of this: "The woman within the disk is the eye of Re, here as mother and daughter; the scarabs emerge from the disk-womb on each side."

Then follows the scene of the hypotenusal pharaoh as Osiris, which we have already considered. The next scene is of the pharaoh in his cultic role of solar priest making offerings to the god Ptah and the goddess Maāt (Cosmic Order), who is shown smaller than Ptah because she was a principle rather than a personality; as this was always understood by everyone, large statues of her never existed, and she was always portrayed as a pervasive but quiet and unobvious presence, sometimes symbolized only by a feather. Ptah is described in this scene as "Ptah, lord of right order, king of the Two Lands, Perfect of face, Who created crafts, One presiding over the great place at rest." This makes it clear that Ptah was the enforcer of the principle of Maāt, and that upholding Cosmic Order was his main job. A very fine image of him can be seen in figure 8.15, which is a photo I took of a magnificent gold statue of Ptah seen in profile.

The final portion of the Engimatic Wall is the vertical panel at the far right showing a resurrection serpent rearing up so high that its head escapes the upper border of the wall decoration entirely, indicating that the dead Osiris has indeed risen and burst through the boundaries of the netherworld.

Figure 8.15. A magnificent small statue of the god Ptah in gold, with a lapis lazuli cap. He is holding a *uas* scepter, which was a sacred scepter used for measuring the calendar and spatial directions (described at length in *The Crystal Sun*). Ptah was the chief god of Memphis, the Old Kingdom capital near Giza. He was merged with the netherworld god Sokar of Giza, and later also with Osiris, to form a trinity known as Ptah-Sokar-Osiris, perhaps the first three-in-one godhead in history. Ptah, however, was always the senior partner of this trinity and was recognized as one of the candidates for creator of the universe. Thoth, god of wisdom and learning, was his son. Ptah had the reputation for being the all-wise intellectual among the gods. There wasn't anything he didn't know or couldn't figure out if he put his mind to it. During the Fifth and Sixth Dynasties, Ptah was unpopular with the pharaohs, and his name was shockingly excluded from the sacred Pyramid Texts inscribed in the pyramids of Saqqara in that period. This is bizarre, considering that his chief temple was just down the road, within walking distance. This hints at some political-religious conflict at the end of the Fourth Dynasty of which we know nothing, due to our lack of historical texts. This statue is in the Egyptian Museum at Cairo. (*Photo by Robert Temple*)

The Enigmatic Wall contains what appear to be no fewer than six golden angles displayed in its figures: four arrows and two hypotenusal mummies. It has been difficult to measure the smaller ones precisely, but they appear to suggest golden angles, whether or not they are exact. In this, a convention appears to have been followed without the artists necessarily appreciating what they were doing, as is indicated by the large Osiris having his golden angle at the top instead of at the bottom.

I hope it was worthwhile giving a full summary of the Enigmatic Wall, so that everyone can appreciate the mythological milieu we are moving in now. The main feature of importance is the large slanting Osiris, who is merely the giant Re-Osiris shown in his hypotenusal form, which manifests the golden angle of resurrection. If we consider the giant Re-Osiris in more detail, we find that he is depicted and described in texts in numerous places. One of the finest pictures of the giant-in-the-horizon is on the beaten gold Second Shrine from the tomb of Tutankhamun, which we see in figures 8.16 to 8.19. I have put descriptions of those scenes in the captions.

The rising of the sun was viewed as a resurrection, and this had direct relevance to every Egyptian, because it was considered a model for his or her own hope of personal resurrection. As Hemingway would have said, *The Sun Also Rises*, although his title was a quotation from the poet John Donne.

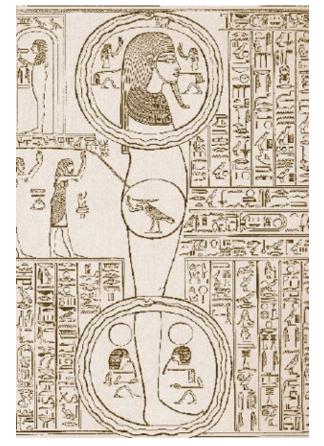

Figure 8.16. This is the giant solar Osiris of the eastern horizon seen in figures 8.17 to 8.19, depicted in beaten gold on the Second Shrine of Tutankhamun. The large encircling serpent swallowing its own tail (called in Greek a *uroboros*) is here called Mehen, which in Egyptian means the Enveloper. The Mehen serpents in general were friendly, protective serpents of the netherworld who wrapped themselves around Osiris and royal mummies to keep them safe. This drawing is taken as a detail from Alexandre Piankoff, *The Shrines of Tut-Ankh-Amon*, Pantheon, New York, 1955, figure 41, opposite page 120.

Figure 8.17. The head of the giant solar Osiris of the eastern horizon, the full figure of which may be seen in figure 8.16. The figure is in beaten gold on the Second Shrine of Tutankhamun at the Egyptian Museum in Cairo. (*Photo by Robert Temple*)

Figure 8.18. This is the middle of the giant solar Osiris of the eastern horizon shown entire in figure 8.16. It is of beaten gold, from the Second Shrine of Tutankhamun. The solar disk fills the belly of the Osiris mummy in the netherworld, and in the center is seen the solar *ba*-bird, representing the spiritual force of the sun, who is about to emerge and be resurrected. The figure to the left is worshipping him as light streams from the solar disk toward him. (*Photo by Robert Temple*)

Figure 8.19. This is the bottom of the image of the giant figure of the solar Osiris shown entire in figure 8.16. The image is in beaten gold on the Second Shrine of Tutankhamun. His feet are in herit, the Place of Destruction at the bottom of the netherworld, where the evil dead meet their doom after indescribable agonies. (*Photo by Robert Temple*)

The way in which the sun rises, especially at Giza, was thought of as *at the golden angle*. The sun as an Osiris came alive, transformed himself into a Horus, and did so as a hypotenuse of a triangle formed by the beams of light as they streamed over the horizon. The surface of the Earth was, quite naturally, the base of the triangle. The Egyptian name of the base of a sacred triangle was, as Plutarch informs us, Isis. The altitude was called Osiris. The hypotenuse was called Horus.<sup>23</sup> Although Plutarch is speaking here of the Pythagorean triangle, it is likely that the same terms were used when speaking of any right-angled triangle that had a religious significance. That Osiris was the vertical altitude of the triangle may be associated also with his upright phallus. It is only natural that the joining or "mating" of Isis and Osiris within the triangle would give birth to a hypotenuse: their son, Horus. In fact, Plutarch specifically calls the hypotenuse "their offspring."

In the Pythagorean triangle, where the square of the hypotenuse is equal to the squares of the other two sides (and the Egyptians and Greeks really drew squares on them, and did not merely write algebraic symbols as we do; see the Byrne title page, figure 7.26), it was justified then to speak of the hypotenuse (Horus) as the "resultant" or "child" of the other two sides. In the passage of Plutarch where he gives these names, Plutarch uses the Greek word *apotelesma* to describe Horus as a hypotenuse, which means final completion, event, result. In the three translations that exist in English, Griffiths translates it as "the

perfected achievement," Babbitt translates it as "perfected result," and King translates it as "the result." Babbitt and King also call Horus as a hypotenuse the "child" of Isis and Osiris as base and altitude, respectively, and Griffiths uses the expression "offspring." It was considered that the "powers" (i.e., the squares) of Isis and Osiris when combined gave the "power" (i.e., square) of Horus. This is a remarkable mythological expression of a geometrical fact, but it is typical of the way the Egyptian priests thought. Although the golden triangle is not a Pythagorean triangle—in that the sums of the squares of the base and altitude do not equal the square of the hypotenuse—we may assume that the underlying principle of the Pythagorean triangle was a resonant presence in their minds, like the bass accompaniment in music, and that when they spoke of the hypotenuse of the golden triangle formed at the rising of Osiris as a Horus, they still thought of him as the child of Osiris. But in this case, he was more than just the child; he was the resurrected Osiris himself. This concept is illustrated in a drawing from the tomb of Rameses VI in figure 8.9, showing Horus arising from the body of Osiris at dawn, which was the great transfiguration of the sun and by extension of all the blessed dead. From the mummy of Osiris, the child Horus emerged, and this was the essence of resurrection. This was Horus-in-the-Horizon.

The "word" of the rising sun, expressed as light rays, streamed through the air as Horus, from the horizon, traveling over the path on the ground called Isis (the base of the triangle), and struck the top of the altitude of that triangle on each of the three Giza pyramids, creating three triangles with acute golden angles. Since the tips of the triangles were pyramidions (mini-pyramidal apexes) thought to have been encased in gold, there would have been brilliant solar flashes on these peaks. These flashes would have taken place in a series of three: first the tip of the Great Pyramid would flash, then the slightly lower tip of the Pyramid of Chephren, and finally the lowest of the three, the tip of the Pyramid of Mycerinus. They gave a three-flash sequence to herald the dawn.

Figure 8.20. This is a drawing taken from the wall of the Sarcophagus Hall of the tomb of King Rameses VI in the Valley of the Kings near Luxor. Here we see a very explicit resurrection scene where Horus, "the Son of his Father," rises at dawn as the sun (the solar disk is beside his head to make this clear, and the fact that he is still rising and emerging is shown by the fact that he does not yet stand clear) and becomes Horus-in-the-Horizon. He is emerging from the mummified Osiris, who is in his golden-angled form, though here Osiris is actually shown in a *double* golden-angled form, with both his upper body and his legs being hypotenusal. The women standing to either side are the sisters Isis and Nephthys, who guard the sacred egg that contains the scene taking place at the horizon. The ultimate location for this sacred event was at Giza, precisely at Rostau, in front of the Sphinx, from where the resurrected Horus shone as rays of light (the "speech," or *logos*, of the sun) directly upward at the golden angle to strike the gleaming golden tip of the Pyramid of Chephren and give the dawn flash (see text). The wall text says: "This Great God [Osiris] is like this in his egg which is in the Netherworld. Horus comes out of the body of his father, and praises him who has procreated him while the two goddesses join his body. This Great God [Osiris] speaks to him while he sees the rays of his disk." (*Drawing and translated text taken from Alexandre Piankoff*, The Tomb of Ramesses VI, *Bollingen Series 40:1 (New York: Pantheon Books, 1954), figure 116, pp. 364–5*)

In New Kingdom times (1570–1070 BC), when the Egyptians could no longer construct pyramids, they continued these practices by using gold-tipped obelisks instead. I have discussed this use of obelisks in great detail in *The Crystal Sun*, where I give illustrations and texts. Solar eyes were sometimes depicted on the tips of pyramids even in the New Kingdom, and this is a reference to the earlier practice at Giza, recorded in old papyri that had survived.

The way the sunrise was observed was that the priests would turn their backs to the eastern horizon and look at the high monument, waiting for the flash, and would then turn and worship the sun in that instant, thus timing their gesture of adoration perfectly, since the sun struck the gold tip first, as it was higher; by the time the priests turned around, the sun would rise at that instant. This was how they achieved their perfect synchronization with the precise moment. To the Egyptians, who were obsessed by ceremonials, this was crucial.

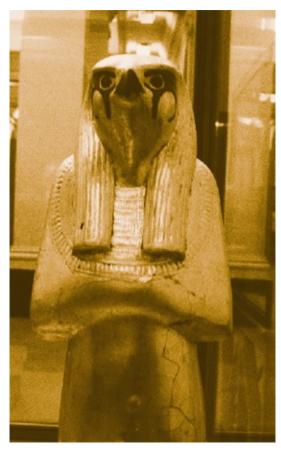

Figure 8.21. A statue covered in gold leaf of a priest wearing a falcon's head to enact the role of Horus. The folded arms beneath the cape are a typical pose of Egyptian priests taking part in ceremonial processions and events, symbolizing secrecy and showing reverence. Such attire may well have been worn by a chief priest observing the sunrise at the time of the equinox at Giza, when Horus-inthe-Horizon appeared. At the moment itself, the priest would have removed his arms from his clothing and held up both hands in a gesture of greeting and prayer. However, as described in the main text, I believe that the priests and celebrants had their backs to the sun just before sunrise, observing the predawn flashes on the east faces of the pyramids (obelisk tips, cased in gold alloy, replaced these in the New Kingdom period), and then turned just in time to see the actual rebirth of the sun, at which point they would have raised their hands in adoration. This statue is in the Egyptian Museum in Cairo. (*Photo by Robert Temple*)

I believe the aerial golden angle that I discovered with the inclinometer from the floor of the Sphinx temple (the horizon) to the tip of the Pyramid of Chephren is a confirmation of this system.

The priests would turn to watch the transformation and resurrection of Osiris, as Horus sprang from the horizon in the form of a stream of light in the sky. To celebrate Cosmic Order, the Pyramid of Chephren was constructed so that it could receive this light at the golden angle, since that was the angle at which "Horus" struck its tip at each equinox. I have not studied the aerial angles of sunrise for the other pyramids or any of the obelisks, and one would have to research the locations from which one would measure the angles. But in the case of the Pyramid of Chephren, it is the Sphinx that determines the angle I found, since the angle is taken from the floor of the Sphinx's Temple. The Sphinx can thus be conceived of as facilitating the golden angle of resurrection by its placement and acting as a conduit for the resurrection by light.

That the light of the sun was conceived of by the Egyptians as the sun speaking, or as his "word," seems to have carried over into the earliest level of Christianity. I show in figure 8.22 one of the strangest early Christian graffito designs. This illustration is taken from a book by the same C. W. King who translated the Plutarch treatise for Bohn's Classical Library that I quoted above as a variant when I gave Plutarch's information about the name for a hypotenuse among the Egyptians. This astounding drawing appears opposite page 90 in King's book *The Gnostics and Their Remains* (1864).<sup>26</sup> The illustration is described by King as "Anubis-Christos." It is the earliest-known depiction of the crucifixion, dating from the late second century AD. It is generally called the Palatine Graffito.<sup>27</sup> It was found drawn on a wall of the Imperial Palace on the Palatine Hill at Rome. There are two accounts of the room where it was found: the first says it was inscribed in a private vaulted cell by a slave who lived there and served one of the early Caesars, and the second says it was inscribed in "a schoolroom," which may actually have been an informal chapel. The name of the man who drew it appears to have been Alexamenos, and he shows himself standing beside the crucified deity with his hand raised in adoration. He appears to be wearing nothing but the short linen garment of someone who has just been baptized or initiated. The inscription in Greek says: "Alexamenos worships the God." King was an expert at analysis of these drawings and stresses that the poorly drawn head definitely represents Anubis and is a jackal head. In other words, the earliest-known drawing of the crucifixion of Christ portrays Christ as Anubis. As time went on, with the many drawings of Anubis that continued to appear on Gnostic gems throughout Roman times, people who had never seen a jackal got the head progressively wrong, and it looked more and more like an ass's or donkey's head. This drawing showing Christ crucified as Anubis suggests a mystic tradition going back directly to the original Giza tradition via the Ptolemaic Netherworld Texts and illustrations, which were themselves drawn from ancient papyri (no longer fully comprehended) dating from the time when the Sphinx was still Anubis, who welcomed the "word" of the sun (logos, later meaning "word" in Greek) at his rising. We know that Logos was St. John's name for Christ. Just to make the connection with the golden angle more obvious, logos also means ratio in Greek, as we have seen. In other words, the "mystery of the cross" is a mystery that goes back to the origins of Egyptian civilization, and Jeschu the Nazarene (better known by the Latin form of his name, Jesus), who spent time in Egypt before his return at the age of thirty to Galilee and Judaea (the original home of his family having been in Galilee at the fishing village of Nahum, known in Latin as Capernaum, which he left as an infant, having been born at Bethlehem in a stable, as the Bible informs us), must undoubtedly, in my opinion, have been deeply learned in Egyptian lore and embodied it in his esoteric teachings. Jesus made himself an actor in a sacred mystery drama, which he lived out in person to enact certain cosmic truths. I believe that some of this drama was directly inspired by Egyptian esotericism that he learned when living at Leontopolis, where there was a Jewish temple larger than that at Jerusalem and where very friendly relations with Egyptian priests and initiates were possible for Jews, because there were no Sadducee fanatics to prevent this happening. The Jews of Egypt were open to many influences, Greek, Egyptian, and Near Eastern, and were not narrow-minded bigots like those to be found in the backwaters of Judaea and Galilee, where intolerance was a mania. The name Jesus of Nazareth is incorrect, because the village of Nazareth did not exist at the time of Jesus. It was founded only about four hundred years later. The historical Jesus was not Jesus of Nazareth at all, but Jesus the Nazarene, describing his affiliation or generic similarity to the vegetarian sect of the Nazarenes, who were opposed to the Sadducees and held to a mystical form of Judaism, rejecting total subservience to the Law of the harsh rabbinical form of the politicians of Jerusalem. When the Roman Church gained control of Christianity with the power of the Roman state

behind it, executing all the people whom they called heretics (i.e., opponents) and burning the large number of gospels they didn't like (such as the Gospel of Thomas and the Gospel of Philip, which were

recovered at Nag Hammadi in 1947), they altered the texts in the four gospels they chose to retain so as to eradicate the word *Nazarene* (a sect opposed to them, who took their name from *nazara*, "the truth" in Aramaic, although "the truth" in Hebrew is generally called by the name of *emet*), substituting *of Nazareth* for *the Nazarene* and claiming they were correcting a scribal error. That is how the phrase "Jesus of Nazareth" got into the surviving gospels: it was interpolated by censors. They could not strike out "Nazarene" completely, because it was too well known, so they circulated the story that "Nazarene" really meant "man from Nazareth," which it does not, and which in any case was impossible because there was not yet any Nazareth for Jesus to have come from.

But what is the meaning of the crucifixion? This is the remaining piece of the puzzle. The fact is that the crossbar of the cross represents the major of the upright of the cross divided in golden section, and by combining them (whether intersecting or as a top bar does not matter), one was portraying the golden section by a symbol, the cross. Early drawings of crosses often had footbars as well, as this one does, and that was the minor. So the footbar is the minor, the crossbar is the major, and the upright is the sum of the two together. The minor and the major are in a ratio (*logos*). Crucified on the cross is the Logos himself, Christ. And for a sacred figure to be crucified means for that figure to be "nailed to the cross," that is, *fixed in correct proportion with the cosmos by means of the divine proportion and sacred ratio, the golden section.* By this means, the sacred figure of a god is "nailed to Maāt" and exemplifies Cosmic Order. Just as Osiris was resurrected as Horus, "the Son of the Father," so too Christ is resurrected as "the Son of his Father," but first both must be crucified, must appear aloft in golden section. *The Logos must be crucified to give the promise of eternal life by his resurrection.* On the basis of such insights, one might create an esoteric and purified Christianity, if people could free themselves from fanatical literalism, which is doubtless expecting too much.

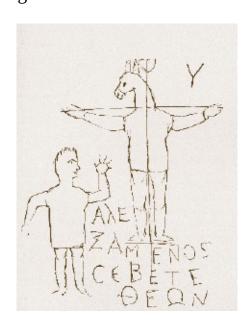

Figure 8.22. The oldest-surviving depiction of the crucifixion shows Christ crucified as Anubis, with a jackal head. This drawing is known as the Palatine Graffito. (*From C. W. King*, The Gnostics and Their Remains, *Bell and Daldy, London, 1864, plate opposite p. 90*)

The earliest Christians, presumably the Gnostic ones, wished to make it clear that the symbolism of the crucifixion had its origins in Egypt, in the presence of Anubis. Thus I believe that the distant memory of the Sphinx as Anubis was passed on without people even knowing its significance any more, but due to the conservatism of religious traditions, this lore continued, thousands of years after it had been possible to give it a rational explanation.

It is interesting that the Christian Gnostics were not "people of the Book." There are known to have

been more than two hundred gospels freely circulating among the early Christians in those formative days, and it was only after the Roman emperors created a Roman Church that all were burned but four, which were declared canonical by a council of clergy presided over by the emperor, acting as an instrument of state. (The Roman Catholic Church has that name because it was created as an organ of the Roman state. The reason it is so political is that it was created to be political by someone who ruled an empire.) The Gnostics, who were persecuted and burned at the stake by the Catholics, did not want to go around killing people because they held variant opinions. Thus, we may view the intolerant form of Christianity as a perversion created by a Roman emperor, just as the intolerant form of Islam known as Wahhabism or Salafism, which only originated in the eighteenth century, was a perversion adopted and propagated by Saudi kings. In both cases, the original purposes were political. (In the case of the Saudis, they were trying to bolster their legitimacy, because they had seized the "sacred" cities of Mecca and Medina by military force in the 1920s from the Hashemites, who had been the guardians and custodians of those cities for a thousand years. To prove they were worthy in religious terms, they adopted an extreme and insane form of Islam to appear to be more pious than any other Muslims in history, as a means of compensation and as a public relations exercise. Unfortunately, this innovative form of Islam has now, due to propaganda funded by oil money, come to be seen as somehow ancient and authentic, which is one of the greatest lies in history.)

It should be mentioned also that the Jews have never been known to want to convert people, and they try very hard to discourage conversion to Judaism, as friends of mine tell me who have married Jews and attempted to convert. In this respect, they somewhat resemble the first Christians, the Gnostics, who, although wishing to spread the "good news" (evangelium, "gospel"), were not going out and beating people over the head or threatening to slit their throats with scimitars to make them accept the "good news." However, whenever religions become aligned with states, persecution commences, and this has happened in Judaism as well. During the time of Jesus the Nazarene, the ruling establishment Jews of Jerusalem were known as the Sadducees. During Jesus's lifetime, the Sadducees are estimated to have executed no less than six thousand Pharisee rabbis who held a different view of Judaism from themselves (but not the same as that of Jesus, whose view was different again), in a ruthless political attempt to seize total control of Judaism and create a state form of the religion based in Jerusalem in which no variation of doctrine would be allowed upon pain of death. However, in Egypt at that time, there were an estimated one million Jews, living at three centers: Alexandria, Leontopolis, and Elephantine Island. Because these Egyptian Jews, who vastly outnumbered the Palestinian Jews, were not caught up in the Sadducean politics of Jerusalem, the Gnostics were stronger in Egypt, and the absorption of Egyptian religious symbols and concepts was greatly facilitated. It is from this background that the crucified Anubis at Rome comes.

In *The Crystal Sun*, I published a color photo (as plate 22) of the sun as represented on the famous astronomical ceiling of the Temple of Denderah. The rays of the sun in that photo are shown as streams of little triangles, as if the sun was spitting triangles, and it makes clear that solar rays were conceived of as specifically triangular phenomena. As I pointed out in that book also, we are told explicitly by the Roman author Pliny that the Egyptians considered their triangular obelisks to be "petrified descending light rays," in which light had been frozen in stone. But I cannot repeat my lengthy account of the optical aspects of obelisks here, as that has already been done in my earlier book, in the context of my discussion of the ancient history of light technology and the use by the ancient Egyptians of crystal lenses, of which I found many examples languishing unappreciated in museums. (I was able to demonstrate that the technology for optical surveying existed in the Fourth Dynasty and prove that optical magnification was used by Egyptian craftsmen for microscopically carving ivory as early as predynastic times, circa 3300 BC.)

According to the French Egyptologist Alexandre Moret, as early as the Pyramid Texts of the Fifth Dynasty, there was a Ray god named Ihhu, "of which the word-sign shows precisely the sun projecting its luminous triangle, divided by a bisector which gives to that triangle a 'pyramidal' appearance." Moret then mentions "the numerous examples where, above all in the paintings of the sarcophagi, the solar disc is depicted projecting some rays which are composed of little triangles packed one on top of the other, from which we have the word sign." He adds that a triangle also figures in the name of Sepedu, god of the Eastern Horizon.<sup>28</sup>

There is a great body of lore of triangles embedded in Egyptian texts and sacred illustrations that has never been investigated properly, because Egyptologists are not geometricians or mathematicians, and also they have not been looking for these things. Above all, the importance of the golden angle and its resultant golden triangle has not been appreciated. Now that we have seen that the Giza Plateau and its main monuments are all interrelated geodetically by multiple interlocking golden angles, all the triangle lore that has always infused the most esoteric aspects of Egyptian religion and design science can be seen to be one of their deepest secrets. We can now appreciate the amazing profundity that geometry had for them. The knowledge of geometry was to them like nuclear science and quantum theory are to us, a way of getting at the heart of matter by elucidating the concealed structures that govern the Cosmic Order. Egyptian religion was, in essence, a sacred science. But what is most surprising of all is that their sacred science was not built on mere superstition and fancy; its fundamentals *are all true*.

What was true in the Age of the Pyramids is true now: golden angles are real, not imagined; the golden section is a universal phenomenon true on all worlds at all times throughout the universe. This is genuine cosmic structure, and it elucidates real Cosmic Order. The number 1.618, which defines the golden section and is called by us *phi*, exists in the most distant galaxies. It is true everywhere, just as *pi* is true everywhere. These are facts from which one cannot "move on." With our mania for the new, we cannot escape the old. The rules of fashion do not apply in geometry. Some things are eternal.

Can it be that the Egyptian civilization lasted for 3,500 years because politicians were not allowed to "move on," and because there was no "media class"?

I mentioned the Temple of Denderah, which contains the most famous and bizarre of all known crypts of ancient Egypt. It is a mystifying and sacred place, which stays with you once you have entered it. Most people we know who have been there have never been able to get it out of their minds and say they keep thinking about it and often even dreaming about it. This is a crypt that celebrates the golden angle as applied to resurrection. The crypt has been discussed by innumerable "alternative authors," though Egyptologists themselves rarely mention it, because they don't know what to say, it is so weird. Some authors have claimed that the strange objects held by figures in the wall carvings represent ancient lightbulbs or other fantastic machines of even more advanced technology, such as ray guns. When Olivia and I first saw these reliefs, we called them "snake aubergines" (aubergines are what Americans call eggplants). They really do look like aubergines, and for gardeners and gastronomes like ourselves, that is what they suggested, rather than lightbulbs. However, they do also look rather like huge aubergine-shaped neon lightbulbs. So what are they? They are shown in figures 8.23 to 8.35. It is worth studying these rather closely, because they relate to our subject, and also because they have become a matter of such sensational interest to readers around the world.

This crypt is in a temple that has many crypts, but this is the only one with these mystifying and puzzling designs (or at least the only one so far discovered, as I suspect there are other crypts at a lower level, and even more at the same level; both of which I believe I have discovered evidence of by detecting either unopened hollow spaces or potentially or formerly movable stones). However, I have

never made a proper study of the Temple of Denderah as I have of the Temple of Seti I at Abydos, where I did officially sanctioned work, and of which I have written a comprehensive survey of previous publications, together with a full analysis of published data, and the results of a full and intensive structural investigation and dating study, which awaits publication at some appropriate opportunity and reveals surprising discoveries.

The narrow Denderah crypt with the "snake aubergines" is technically known as Chamber C of South Crypt Number One. The wall carvings and textual inscriptions were first published in 1947 by the great French scholar Émile Chassinat in his massive series of volumes *Le Temple de Dendara*, published in Cairo by the French Institute. The texts and carvings appeared in volume 5, which itself was a double volume. For many years it was impossible to obtain these books, and they could be consulted only in a few specialist libraries. But in 2002, the French Institute reprinted them, and they became freely available to individuals again. Although of course the books are in French, both the hieroglyphic texts (which are not translated) and photographs speak for themselves, the former to Egyptologists of any language and the latter to everybody. As for the texts, they have fairly recently been translated from Egyptian hieroglyphics into both French<sup>29</sup> and German. I can read the German version myself, and for the French version, I am grateful to the young Egyptologist Tessa Dickinson, who is bilingual, for translating the relevant passages into English. I shall be quoting from her translation, with a few amendments made by myself. These texts explicitly state what the images are meant to represent.

Figure 8.23. A plate from Chassinat's *Le Temple de Dendara*, volume V, showing the right half of the north wall of the underground "serpent cell" crypt. There is only one serpent cell on this wall, and the netherworld's avenging angel, Uputi, stands before it with his raised knives. Normally he cuts off the heads of the evil dead, but here he stands guard. He wears a monkey skin and has the head of a frog. Because the monkey skin is clearly depicted (see close-up photo in figure 8.33) being worn as a costume, this scene may represent a ritual carried out in the temple, even in this very crypt. If so, the scent of the blue lotus must somehow have been available. The chamber might have been filled with the blossoms at the proper season, or otherwise some method of capturing the scent and the alkaloids in concentrated form may have been used. Since the Egyptians do not appear to have practiced distillation, this may have been done by a process resembling enfleurage or maceration, which are still used at Grasse by the French perfume industry as the only means of capturing the delicate essences of flowers such as violets (the scent of violets does not survive distillation in the way that the more robust attar of roses does, and can never be obtained by that method). The absorption of the active principles of the flowers by a purified fat preserves them indefinitely, provided a natural preservative such as gum benzoin is used to "benzoate it" and prevent it becoming rancid. This fat could then have been burned on a brazier, releasing powerful waves of the scent to provide a deeply scented atmosphere in a closed crypt like this one, into which only a few people can fit. It is possible that the concentrated essence of the blue lotus may have some remarkable property discovered empirically by the ancient Egyptians and unknown to us.

Figure 8.24. A plate from Chassinat's *Le Temple de Dendara*, volume V, showing the left portion of the south wall of the crypt, with one of the two serpent cells issuing from a blue lotus, beneath which crouches a worshipper in prayer. On a plinth at right, one of the sons of Hathor (lhy or Harsomtus), with a solar disk on his head, supports the serpent cell, with his arms raised in the *ka* position. The serpent representing Resurrection is coming out of the blue lotus, the sacred flower that exhales the scent of immortality. A line drawn from the point where the son of Hathor's left hand supports the end of the serpent cell to the end of the top of the baseline of the central panel at the exact corner of the chamber forms a golden angle with the top of the baseline. The serpent cell and its serpent of Resurrection are thus generated by a golden angle.

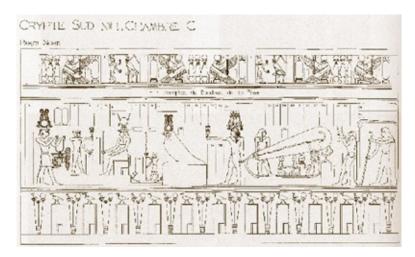

Figure 8.25. The drawing from Chassinat's *Le Temple de Dendara*, volume V, showing the north wall of the "serpent cell" crypt. The solemn figure of the underworld god Sokar sits on a plinth slightly to the left of center, presiding over the scene. My close-up photo of this image is seen in figure 7.6, where the hieroglyphic name Sokar is clearly visible beside his head. To the right is the north wall's sole serpent cell, facing which is the netherworld's avenging angel Uputi with his knives (see figure 8.33 for a close-up view of him). Here he is protective, but his normal role is to cut off the heads of the evil dead. (In the German translation of the texts, he is called merely Upu, which was a shorter form of his name.) The enthroned figure at left is the goddess Hathor, with her characteristic headdress. She is receiving an offering from one of her sons, either the younger son, lhy, or the older one, Harsomtus. Behind her, at a much smaller scale, a man in a netherworld boat, possibly representing the pharaoh, is sailing, holding a staff topped with a blue lotus flower, from which a Nehep serpent symbolizing resurrection is leaping. The figure presenting an offering to Hathor from behind the statue of Sokar is shown as a child of Hathor by his side locks, and is either her older son, Harsomtus, or the pharaoh portrayed as honorary son.

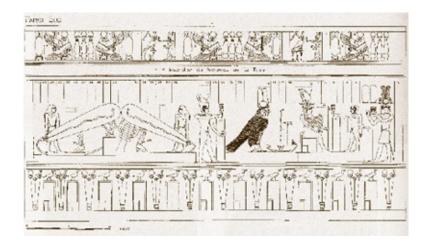

Figure 8.26. The drawing from Chassinat's book *Le Temple de Dendara*, volume V, showing the south wall of the "serpent cell" crypt. Here there are two serpent cells facing one another at left. The enthroned goddess seated at right is Hathor, in her characteristic headdress, and holding a *uas* scepter. An offering is being made to her by one of her two sons, probably the younger one, lhy, who holds an ankh, symbol of life, in his left hand. The figure making an offering behind the figure of Sokar is probably Hathor's older son, Harsomtus, wearing the joint crowns of Upper and Lower Egypt. Both sons are shown with the side lock, indicating their status as children of the goddess. (It is possible that the "son" with the crown is meant to be the pharaoh, granted honorary sonship in this instance.) The Sokar figure and the Nehep serpent symbolizing resurrection are seen in close-up in figure 8.27.

The reliefs in the crypt show three "snake aubergines" in total, one on the north wall and two on the south wall opposite. What is important about these "snake aubergines" from our point of view is that they are drawn at golden angles to the horizontal. We suspect there must be something strange going on, and there is.

I have given a lot of information about the images in the captions to the photos and drawings, so here I will give a summary account, omitting many of the details of the images, which I leave for the captions, where they may more appropriately be read at the same time as studying the pictures.

I was unable to get far enough back in the narrow crypt to obtain flat images of large sections of wall. These are, however, available in black-and-white photos from the 1940s, lit by professional equipment and exposed by time exposures on tripods, in the Chassinat volume. So my color images taken with a flash need to be supplemented by the Chassinat black-and-white images, which I have reproduced here for comparison. I have also reproduced Chassinat's drawings of the wall designs so that the entire walls can be seen in their total contexts. Otherwise, impressions might be misleading. Mistakes are often made in Egyptology by failing to consider whole contexts of strange phenomena; the main example of that is the Giza Plateau, where the Great Pyramid and the Sphinx have usually been studied in isolation rather than as part of a complex including the other two pyramids as a unified conception (but as we have seen, only by considering them as a whole was it possible for me to discover the Giza Golden Plan).

If we start first with my figure 8.27 below, we can see the netherworld falcon Sokar, and immediately before him is a snake sailing in a netherworld boat, standing on its tail. This is one of the Nehep serpents that we have already encountered and that symbolizes resurrection. We can see that we are in familiar netherworld territory.

In figures 8.25 and 8.26 from Chassinat's book, we can see the entire south wall and the entire north wall represented in drawings. It is impossible for anyone to photograph them in their entirety, as the crypt is too narrow to allow that. In figure 8.26, we can see that the Sokar and Nehep figures that we see in figure 8.27 are in the center of the wall. The left portion of that wall is taken up with two bizarre "snake aubergines." These strange shapes are really "serpent cells," and we shall call them that from now on. If we look at figure 8.28, which is my close-up photo of the right serpent cell, we can see that it issues as an emanation from an upward-curving lotus flower, which is, in fact, the famous blue lotus of the ancient Egyptians, a rare plant that is now verging on extinction and has a flower of a subdued and somewhat pale mauve-blue color. It is a mysterious plant, and its flower is delicate and eerily beautiful. Although it has a lovely fragrance, that fragrance is very faint, so you really have to smell hard to detect anything other than a vaguely pleasant smell of a singular delicacy. It does not appear to possess any obvious narcotic properties. I wonder if there may have been a variety of blue lotus in ancient times with a more powerful and obvious odor. This is the magical flower that was always being held to the noses of the pharaohs and the gods in sacred art, since its scent represented the breathing in of an essence that could stimulate and provide immortality. Prows of sacred ships, especially netherworld boats, often consisted of these curling lotus stems issuing forth in flowers that bent backward. Superficially, the wall relief shows a man who

appears to be carrying the serpent cell, but this close-up view demonstrates that he is not even touching it, and his hand is rigidly and vertically down in the reverential position of a sacred procession. The serpent cell is thus entirely independent of him; he is a mere attendant. A long, thin serpent is issuing out of the blue lotus, inside the serpent cell. Olivia has always thought that the blue lotus contains a sofarunidentified magic ingredient, possibly an elusive or volatile alkaloid, and maybe even in its stem or bulb.

Figure 8.27. At left is the netherworld god Sokar in his falcon form (from the solar disk on his head, two large plumes arise, which are not visible in this photo). To his right is the Nehep serpent standing upright on its tail and sailing in a netherworld boat. It represents resurrection (*Nehep* comes from the Egyptian verb meaning to leap up). This scene is on the south wall of the crypt. (*Photo by Robert Temple*)

Figure 8.28. This is the right serpent cell of the south wall of Chamber C in the Denderah crypts. This close-up photo shows how the cell and the serpent are issuing forth from a lotus flower (in fact, it is the sacred blue lotus of the lotus god Nefertem, which was frequently held to the nose by royal and sacred figures to indicate the breathing in of the essence of immortality). I did not notice this fact, because I persisted in the amusing notion that the serpent cell looked so much like a huge aubergine (eggplant) that I could not get any other image of it into my head. It was Olivia who pointed out to me that this was a lotus flower from which the cell and the serpent were emanating. She is far more visual than I am. It is also the case that the standing figure behind the cell is neither carrying nor supporting the serpent cell, as his hand may be seen not to be touching anything. Instead, this serpent cell is being supported entirely by the Djed pillar with arms, which is shown in figure 8.30. (*Photo by Robert Temple*)

Figure 8.29 is a close-up of the left serpent cell of the south wall. Here again we see the serpent cell and its interior serpent clearly issuing from the blue lotus flower. In figure 8.30, we can see a close-up of the front end of the right serpent cell of the south wall. A worshipper kneels beneath the serpent cell in a posture of prayer. The serpent cell itself is supported by what is called a Djed pillar, with upraised arms

in the position of a ka (a kind of soul, the "double" of the deceased person) emanating from the sides of the Djed; this picture of a ka may be part of an unrecognized cryptopgraphic inscription, or it may be purely iconographical. Another ka emanating from the top of a Djed this time supports the single serpent cell on the north wall, as seen in figure 8.32. Here the ka arms penetrate the serpent cell and directly support the serpent within. The Temple of Denderah is sacred to the goddess Hathor, and she may be intended to be the goddess seated in the boat, supporting the serpent cell with her head. (Since her pose is that of a hieroglyph, as are the ka and the Djed, a cryptographic statement may be intended here.) This Djed sits on the prow of this particular netherworld boat, whose stern curves around and becomes another blue lotus blossom from which emanates the serpent cell of the north wall, as seen in figure 8.25. In the former photo, figure 8.31, to the right of the Djed a male child crouches on a plinth, with a solar disk above his head and his arms upraised in ka position to support the far end of the serpent cell. This is one of the two sons of Hathor, either Ihy or Harsomtus. He is shown with the side lock of hair that indicates he has not yet come of age and emphasizes his status as child of the goddess. The serpent, whose head is shown so clearly here, represents the resurrected and emerging life of the risen sun, which has been breathed out by the sacred lotus flower.

The netherworld aspects of these strange pictures are highlighted by the presence on the north wall of the terrifying Uputi, a messenger demon of Osiris and an avenging angel, whose main job was to hunt down the evil dead, like a relentless detective, and chop off their heads as soon as he found them. On the north wall he stands with knives held up in each hand, ready for action, but in protective mode. We can see Uputi in figure 8.33. He wears a monkey skin and has the head of a frog. Uputi's monkey skin is so obviously a costume that we may have a depiction of a priestly ritual here, rather than of the netherworld itself. He is standing guard over the north wall's only serpent cell.

Figure 8.29. This is the left serpent cell of the south wall of Chamber C. Once again, the attendant is not carrying it or touching it. In this case, the lotus flower from which the cell and serpent are emanating curves around, and its stem (to the right of the photo, not visible here) turns into the prow of a nocturnal solar boat. The knees and hands of a praying figure may just be seen at bottom right. (*Photo by Robert Temple*)

Figure 8.30. The Djed pillar, here quaintly portrayed as animate and raising its arms supportively, was sometimes described as the backbone of the god Osiris. It was meant to symbolize stability and correct orientation. It may have had a connection with surveying and the use of angles, concerning which see my discussion of this subject in *The Crystal Sun*. The raised arms also are a hieroglyphic sign for ka, which is one of the various types of soul, often called a person's double or the animating principle of a being that survives death. In The Crystal Sun I point out that the raised arms may also have been a feature of surveying, when the correct orientation to the cardinal points was being sought for a sacred building and a sighting was being taken, with the person being looked at through the proto-theodolite (using the ancient lenses I have discovered and described) holding up his arms, and something resembling the Djed being a graduated measuring instrument for sighting. It is possible that the textual inscriptions in this crypt contain some supplementary or variant statements using cryptographic writing, in which case the raised arms may actually be read as ka and form part of an unrecognized textual statement. I do not believe that anyone has ever considered the inscriptions in this crypt from the point of view of hieroglyphic cryptography. It is not impossible that there may be two separate translations of some of the hieroglyphs in this crypt, the obvious reading and the concealed reading, (Photo by Robert Temple) Figure 8.31. On the right, the god lhy, son of Hathor, crouching on a rectangular plinth (which, if taken as having its base at the level of the adjoining base on which the goddess sits, is a golden rectangle) and with a solar disk on his head, holds aloft the serpent cell of the emerging life of the rising sun. In the center, support is also given by the Djed pillar (often known as the spine of Osiris) with upraised arms in the form of the symbol for the ka, so the cryptographic meaning is probably "the ka of Osiris." At left, a goddess sits supporting the serpent cell with her head; she is probably Hathor. She and the ka of Osiris are riding in a nocturnal boat, with the Djed at its prow; this boat is made of the stem of the sacred blue lotus of Nefertem. The actual serpent representing the resurrected and emerging life of the risen sun, which has been breathed out by the sacred lotus flower, is directly supported by the raised arms of the ka of Osiris, and not merely by its cell. (*Photo by Robert Temple*)

Figure 8.31. On the right, the god lhy, son of Hathor, crouching on a rectangular plinth (which, if taken as having its base at the

level of the adjoining base on which the goddess sits, is a golden rectangle) and with a solar disk on his head, holds aloft the serpent cell of the emerging life of the rising sun. In the center, support is also given by the Djed pillar (often known as the spine of Osiris) with upraised arms in the form of the symbol for the ka, so the cryptographic meaning is probably "the ka of Osiris." At left, a goddess sits supporting the serpent cell with her head; she is probably Hathor. She and the ka of Osiris are riding in a nocturnal boat, with the Djed at its prow; this boat is made of the stem of the sacred blue lotus of Nefertem. The actual serpent representing the resurrected and emerging life of the risen sun, which has been breathed out by the sacred lotus flower, is directly supported by the raised arms of the ka of Osiris, and not merely by its cell. (*Photo by Robert Temple*)

Figure 8.32. The serpent cell of the north wall, issuing from a blue lotus flower that curves out of the keel of the netherworld boat, upon the prow of which sits a Djed pillar that supports the serpent with the serpent cell by means of two upraised *ka* arms. Two worshippers sit beneath the serpent cell facing one another, supporting the serpent cell with their heads, as does the goddess beyond them to the right, who is presumed to be Hathor. (*Photo by Robert Temple*)

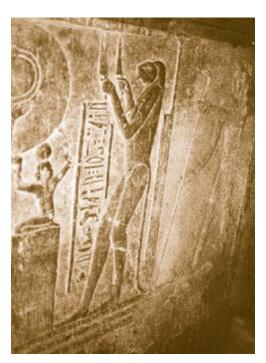

Figure 8.33. The central standing figure is Uputi, a netherworld personality with the body of a monkey and the head of a frog. The Uputi demons were the avenging angels of the Egyptians. They were completely harmless to good people who died, but as they had a violent hatred of evil, they relentlessly sought out the evil dead, decapitated them with their sharp knives, and turned their bodies upside down. It was the fate of all evil Egyptians after death to live upside down and decapitated in pits where snakes and vermin crawled all over them and eternally ate away at their heads and bodies, while they suffered a variety of other untold tortures too terrifying to enumerate. The only extended account of the Uputi demons is in J. Zandee's *Death as an Enemy*, Brill, Leiden, 1960, pp. 202–3. The word *uputi* means messenger, and technically, these Uputi demons were the messengers of Osiris and were assistant judges of the dead. Sometimes a Uputi demon would appear to someone about to die as an angel of death. As one spell in the *Book of the Dead* says: "When your messenger comes to fetch you, he finds you prepared. Do not say: I am too young for being taken away." And in a Coffin Text spell, the deceased is advised to say: "Oh savage ones of face, messengers of Osiris, who close the mouths of the spirits over what is in them. You have no power over the closing of this mouth of mine. You do not take away the going of these feet of mine." (*Photo by Robert Temple*)

Now we come to the true significance of this crypt in terms of what we have been considering about the rising sun at Giza, where the golden angle was discovered to be the angle of resurrection. Here, too, the golden angle is found in a resurrection context. On the south wall, if you draw a straight line connecting the tip of the right serpent head to the upper tip of the lotus flower and then continue it on to the baseline of the central panel, it forms a golden angle with the horizontal, so that the serpent of resurrection is seen to be generated by a golden angle. This is shown in figure 8.34 and can be measured accurately by anyone on top of the drawing in figure 8.26. Similarly, the left serpent cell is generated by a golden angle with the horizontal, which can be measured by a line drawn from the point at the very end of the top of the baseline of the panel at the far left (which is also the corner of the chamber, a fact not made clear in the drawing but seen clearly in figure 8.35), to the precise point where the son of Hathor is supporting the serpent cell with his left hand. This can also be measured very precisely in figure 8.26, because it is a drawing that has been done flat-on. The son of Hathor is in this case literally "upholding the golden angle." Both serpent cells and their serpents on the south wall are thus generated by golden angles.

Figure 8.34. This is the south wall of Chamber C. The serpent cell on the right is being supported by a Djed pillar with arms, and a worshipper is praying beneath it. At far right in the photo is the rear portion of the large south wall's Sokar falcon on a pedestal. As with the opposite wall, a line drawn from the edge of the base of the Sokar pedestal forms a golden angle with one of the serpent heads. In this case, the line touches the tip of the left serpent head. (On the opposite wall, there is only one serpent cell, and the line from the edge of the base of the north wall's Sokar falcon touches the tip of the head of that one's serpent.) The figure in this photo standing between the right serpent cell and Sokar is the pharaoh. The serpent cell on the left is supported by the god lhy, who is crowned with a solar disk, sits on a pedestal, and has the side locks of hair signifying a youth. Ihy was the son of the goddess Hathor, whose temple this is at Denderah. (*Photo by Robert Temple*)

Figure 8.35. This photo of the south wall of the crypt shows the two serpent cells pointing toward one another, with kneeling

worshippers beneath them, the right one supported by the Djed pillar with arms and the left one supported by one of the sons of Hathor (either the god lhy or the god Harsomtus) on a pedestal. Both serpent cells and their serpents emanate from blue lotus blossoms, as the breath of resurrection. The two golden angles that generate the two serpent cells are described in the main text and can be measured on figure 8.26. The prow of the nocturnal solar boat beneath the left serpent cell is shown here; it touches the pedestal on which lhy or Harsomtus crouches (where his left hand supports the end of the serpent cell is a point defining the golden angle with the base). The mortar in the stone wall seems to suggest that there are two small stone blocks beneath the heads of the two serpent cells, which at one time were removable. I am not aware that anyone has ever noticed this or thought of investigating whether they might be removable or lead to something. Perhaps the original excavation records mention something about them. However, in terms of normal construction procedures, it makes no sense at all for these two small blocks to be inserted into the middle of a wall carving, as they disturb the composition. But each is beneath the head of a resurrection serpent, and since resurrection leads somewhere, perhaps these blocks conceal a passage that also leads somewhere. The vertical streak of mortar cutting the right serpent cell, separating two large stone panels, is not unusual, but the two small blocks are definitely suspicious and may well lead to other concealed crypts that could elucidate the strange mysteries of this chamber. I also believe there is another chamber below this one, which has not been entered since antiquity, because I detected by tapping what appeared to be a hollow space beneath the stone at the far end of the crypt from where you descend and go in. Also, in my opinion, an expert at hieroglyphic cryptography needs to examine the inscriptions in this chamber for further or double meanings. Just as golden-angle design construction is not immediately obvious to the untutored eye, so matters may be hinted at in the texts that straightforward translation does not reveal at first attempt. Sometimes in cryptography, figures can double as hieroglyphs, and this may not have been considered yet. (Photo by Robert Temple)

On the north wall, the serpent and its serpent cell are also generated by a golden angle with the horizontal, the angle being shown by a line drawn from the bottom right base of Sokar's pedestal to the tip of the serpent's head. This can be measured by anyone on top of the drawing in figure 8.25.

That is all we need to consider here about the Denderah crypt. Because it has understandably become something of a cause célèbre among those intrigued by Egyptian mysteries, it was worthwhile to show that it is part of the same complex of iconography and thought that we find at Giza in association with the Sphinx. The theme is the same: resurrection and emergence from the netherworld by means of the golden angle of resurrection and, in this case, also by the breath of immortality that comes out of the blue lotus.

There is one more amazing physical manifestation and occurrence of the golden angle at Giza, which was discovered by someone in the nineteenth century who did not realize at the time what it was that he really had discovered. This was a very strange discovery of my own, too, to find it buried in the data in his book. Some time ago I managed to obtain a copy of this extremely rare book on the Giza pyramids written by a British engineer named Robert Ballard. He was a chief railway engineer for Queensland, Australia, in the 1880s. In 1882, he published his remarkable book, The Solution of the Pyramid Problem.31 A main theme of the book is that the pyramids of Egypt, which he had studied as he passed through the country as a visitor in 1858 or 1859, made expert surveyors' backsights for measuring and reestablishing the boundaries of the fields of Egypt after the receding of the waters of the inundation of the Nile. "Backsight" is a surveyor's term for a known point of elevation (in this case, the heights of the pyramids, which would have been known) toward which a surveyor looks back in order to calculate his present height where he is standing with his measuring instrument, which is called a theodolite. In *The* Crystal Sun I discuss ancient Egyptian surveying methods and published the photographic evidence to prove that in the Pyramid Age the Egyptians possessed perfectly ground convex crystal lenses to enable them to construct primitive theodolites in order to obtain the extreme precision of alignment of the Giza pyramids, which was possible only by means of optical surveying methods and requires magnifying lenses. Ballard's theory about the backsights is very interesting. His idea first came to him as he rode the train from Alexandria to Cairo and noticed the pyramids shifting their positions relative to one another as he moved. But in the process of later compiling data to support his theory, Ballard traveled extensively on foot in circles around the pyramids of Giza, doing drawings of them from a variety of angles along a complete circuit of 360 degrees. This was easier for him in 1858 than it would be today, because the

surrounding area was largely empty. Nor was there yet any smog to interfere with his vision. He stressed that the small Pyramid of Mycerinus needed to be covered in red casing stones, as it partially was (Ballard was unaware that in antiquity the red casing stopped halfway up and became white in the upper half, but this need not affect his argument), to distinguish it from the other two pyramids from certain angles for such sighting purposes. In his book, he printed all his drawings in two colors, with the Pyramid of Mycerinus colored pink, to aid the reader's comprehension. As he circled the Giza pyramids in this way, studying their changing configurations in relation to one another, he was arrested at a particular point by a strange sight. Suddenly, at no angular geographical bearing that appeared to be especially significant to him, a kind of optical illusion presented itself. Taking the apex of the Pyramid of Chephren as north for his sighting purposes, the southwest corner edges of both the Pyramid of Chephren and the Pyramid of Mycerinus appeared to blend into one single edge and to become perfectly aligned with one another along their northeast-to-southwest diagonals.

This is very odd, because as anyone can see from the Golden Giza Plan in figure 7.25, the diagonals of these two pyramids are not really in a direct line with one another at all. If those lines were each carried on toward the southwest, they would be perfectly parallel, but some distance apart. If the two diagonals had been really aligned one behind the other, the merging noticed by Ballard would have been seen from a point that was from true north precisely 45 degrees south of west and 45 degrees west of south, which is the direction both diagonals are pointing from their own separate apexes. However, this is not seen, due to the fact that the diagonals are not in line. It is therefore most extraordinary that the two diagonals appear to merge when viewed from an angle all too familiar to us!

The optical illusion then is given of a perfectly triangular chunk being cut out of the southwest corner of the Pyramid of Chephren, with a plug of red stuck in its place into its pale body. (This would have been an even more startling illusion in ancient times, when the casing stones were all in place and their true colors were still bright.) This extraordinary sight is reproduced in figure 8.36, since it is necessary for the colors to be seen for the phenomenon to be fully appreciated. (Bear in mind that Ballard did not realize that the small pyramid was originally only red in its bottom half, so he drew it as wholly red.) Ballard duly made a note of the geographical (not compass) bearing and recorded it as 206° 33' 54.18." He did not see the significance of this angle, and it was assumed to be random. However, he had stumbled on the golden angle without realizing it. The angle just mentioned was viewed from the southwest and is thus 26° 33' 54.18" west of south, which makes a precise golden angle with the north-south meridian passing through the tip of the Pyramid of Chephren. Both the southwest edges of the two merging pyramids as seen along that ray appear to become one. But because the diagonals of the two pyramids are not actually geographically aligned on the Giza Plan, the view recorded by Ballard must be a strange optical illusion whereby two diagonals that are not actually in alignment appear to become so at the precise spot where he stood, which was defined by a golden angle to the north–south meridian. I have not been to Egypt since finding this information in Ballard's book, so I have not been able to take this sighting myself. One does not normally wander southwest of the Pyramid of Mycerinus into the desert unless one goes on horseback or by camel, so this would not normally be seen, even in ancient times. It must presumably have some additional significance yet to be discovered. However, it does not point toward any pyramid farther south, as they are all too far to the east. The line runs toward the Fayyum, but it does not appear to strike anything in particular. This line is deeply puzzling, and perhaps it means nothing outside the Giza Plateau context itself.

This drawing appeared as figure 44 in Ballard's book, one among seven similar drawings on a page, with no special attention being called to it. I had to have a pretty sharp eye to spot this, especially as the

angle was given as a bearing, with 180 degrees added to it, so that in a scan for significant angles such as I always carry out when I look at things, it did not jump out and click with my mental "search image" as a number match. I had to excavate it from the data, which is a different and slower, second-order mental process.

This is my last physically demonstrable golden angle at Giza to be presented in this book. Unfortunately for those of us who like answers, it is the most puzzling and bizarre of them all, and it requires a lot of further thought. It has in common with my inclinometer observation from the Sphinx Temple floor the fact that the tip of the Pyramid of Chephren is at the true center of the optical illusion, and that is certainly a crucially important lead in my further detective work. Obviously, I must obtain some photos of this phenomenon from the desert southwest of Giza when I next go to Egypt. My work on the geometrical mysteries of the Giza Plateau has really just begun. Plotting the spider's web of golden angles is just stage one of unraveling a far more complex Giza Plan. Much more is made clear in my book *Egyptian Dawn*, though I doubt that this subject will ever be exhausted. Or at least, I will be exhausted before it is!

Finally, we can gain further insights into the golden angle of resurrection by considering some further ancient illustrations. First, we can see two other hypotenusal pharaoh/Osirises at golden angles that are depicted in papyri in figure 8.10 and 8.37. The first is one I spotted in a glass case in the Egyptian Museum at Cairo (Papyrus 4891), which appears never to have been discussed by anyone as far as I can discover, and the second is depicted in a well-known papyrus called the Papyrus of Heruben, which has been discussed by Egyptologists on various occasions, and was reproduced by Piankoff. All that needs to be said about these two images is found in the captions to the plates.

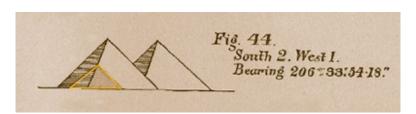

Figure 8.36. This is figure 44 from Robert Ballard's book, *The Solution of the Pyramid Problem or, Pyramid Discoveries with a New Theory as to Their Ancient Use,* John Wiley & Sons, New York, 1882. In his book, the British engineer Ballard walked 360 degrees around the three Giza pyramids (at a time when there were no buildings in the way and no smog), making sketches of the mutual configurations of the three pyramids from a variety of angles and cardinal (not magnetic) bearings. He did this because of his conviction that the pyramids were used as backsights for surveying purposes in ancient Egypt to reestablish boundaries of fields after the inundation waters subsided every year. He made the point that the small Pyramid of Mycerinus had to be a different color (it was partially covered in red granite casing stones instead of white limestone) to differentiate it from the other two. Among the many views Ballard sketched, and for which he meticulously recorded the bearings, was this striking one, where the optical illusion is created of the small Pyramid of Mycerinus (in the left foreground) merging and becoming one with the larger Pyramid of Chephren directly behind it, appearing as a kind of red plug in its corner, with the edges and bases of the two separate pyramids perfectly coinciding so that they look like one pyramid. Ballard duly noted the cardinal bearing of 206° 33' 54.18", or, in other words, by subtracting the 180 degrees from north to south, constituting an angle with the north—south meridian line of 26° 33' 54.18" west of south, which is precisely the golden angle. So Ballard stumbled across another major golden-angle phenomenon at Giza without realizing it, because evidently he did not know the value of the golden angle and did not recognize it. He merely noted the bearing as a matter of routine. I was the one who spotted this in his mass of data.

We have already seen the remarkable images in beaten gold on the Second Shrine from the tomb of Tutankhamun, reproduced in figures 8.16 to 8.19, of the giant Re-Osiris standing at the eastern horizon with his feet in hell and his head in heaven, and the details are given in the captions.

Figure 8.25 is a photo I took of another portion of the beaten-gold Second Shrine of Tutankhamun. Here we have Osiris portrayed as a prone mummy, lying on his stomach, into whose mouth the "voice of Re" (the *logos*) is pouring as a stream of light. This is yet another form of the hypotenusal Osiris rising in

the east at the golden angle. As explained in the caption to the photo, a line drawn from the top of the solar disk through the eye of Osiris, if continued to the base on which he is lying, forms a golden angle with the horizontal plane. This is another clear portrayal of the golden angle of resurrection.

Figure 8.37. This papyrus inside a glass case in the Egyptian Museum in Cairo shows another hypotenusal priest or pharaoh as Osiris. The papyrus is Papyrus J4891, on display in Case 530 in Room 29. Here once again, the mummified pharaoh, identified in his inert state with Osiris, but who through resurrection has "become a Horus," forms the hypotenuse (which was known to the Egyptians, according to Plutarch, as Horus) of a triangle, in this case a golden triangle, such as that projected by a shadow onto the south side of the Great Pyramid at sunset on the winter solstice. (The deceased pharaoh is also affiliated through this means with the mummified god Ptah, who is also "south of his wall," as many inscriptions state.) The angle at the pharaoh's feet, if measured by the line protruding from the top of his head, forms the golden angle. A poor imitation of this portion of the papyrus design from the Twenty-third Dynasty is found in the Papyrus of Djed-Amon-iuf-ankh (the name of a priest of Amun from Thebes, whose funerary papyrus it was), also in the Cairo Museum, and reproduced as Number 27 in Alexandre Piankoff, *Mythological Papyri*, Pantheon Books, New York, 1957. In Piankoff's book, he shows no knowledge of the papyrus in this photo, but as Number 2 he reproduces the Papyrus of Heruben from Cairo, which is shown in figure 8.10, and which contains a very important hypotenusal figure. (*Photo by Robert Temple*)

Another graphic illustration on this shrine of beaten gold of the "call of light" (*logos*) emitted by the sun is found in figures 8.40 and 8.41. The sun as a uraeus serpent spews light into the forehead of a mummy of the blessed dead to reawaken him, and a series of other mummies have rays of light shooting into their foreheads from stars, so they too may be resurrected. In figures 8.46 and 8.47 is another scene from this shrine, in which is depicted Horus emerging from his father, Osiris, in the netherworld preparatory to rising as Horus-in-the-Horizon. This is another version of the same process that we have seen in figure 8.20 from the tomb of Rameses VI.

Figure 8.38. A prone mummy figure of Osiris as the sun in the netherworld, into whose mouth the "voice of Re" as a stream of

light is pouring from a small solar disk. This is in beaten gold on the Second Shrine of Tutankhamun in the Cairo Museum. Directly beneath the small solar disk is a pair of inverted legs, which means movement in the netherworld (which everybody enters upside down). The outstretched arm of the netherworld solar Osiris is the same as the outstretched arm of the hypotenusal Osiris-as-Horus figure rising at Giza, and like it, this figure forms a golden triangle. A line drawn from the top of the solar disk through the eye of the prone mummy strikes the base on which the mummy lies at a point that creates a golden angle, which is the same golden angle of resurrection that we find at Giza, and the angle on which the entire Giza Plan and positioning of the Sphinx are based. At far right, an upright, friendly Nehaher serpent stands in a rectangular array of vertical light rays, above which a pair of walking legs say "moving." Above them, another solar disk is emitting light. At far left, two androgynous, lion-headed figures have had their corpses resurrected by the light of Re, and they are following him. The arms concealed under the cloaks are a well-known priest's pose, indicating that they are carrying secret things, so these figures probably really represent priests in procession wearing lion heads, who represent those resurrected dead, as part of a ceremony. See also the drawing of this scene in figure 8.39 below. (*Photo by Robert Temple*)

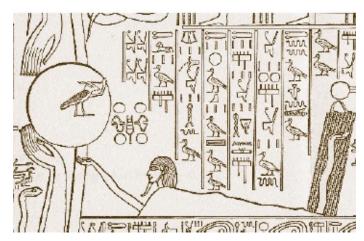

Figure 8.39. A drawing of the scene seen in figure 8.38. Taken from Alexandre Piankoff, *The Shrines of Tut-Ankh-Amon*, Pantheon, New York, 1955, figure 42, opposite page 128.

Figure 8.40. This mysterious scene in beaten gold from the Second Shrine of Tutankhamun shows a cobra called the uraeus spouting a stream of light from its mouth. According to one of the creation traditions of the Egyptians, the divine "word" (which became the logos of the Greeks and later the Logos of the Gospel of John in the Bible, where "In the beginning was the Word... .") was uttered, and creation came into being as a result. However, what the Greeks and Christians missed in this concept, when they later adopted it, was that the "word" was not meant to be audible, but was in the form of light. To the ancient Egyptians, the sun (Re) "spoke light." Here, the "word" or logos as a stream of light strikes the forehead of the first of a row of sacred mummies (there are two more to the right, beyond the photo). The uraeus represents Re, the sun, and the stream of light is meant to be the graphical representation of the voice of Re, who had a "fiery call." Each mummy also has a star sending rays of light into his forehead. In front of each mummy is its ba, its spiritual force that has survived death. The ba was depicted by the Egyptians as a bird with a human head, the bird body symbolizing the ability of the ba to flit around wherever it likes, like a bird. Above the head of each ba in this picture is a pair of striding legs, to emphasize the mobility of the ba. Re is "calling" the bas. Each ba is standing on four vertical light rays. As John Darnell says: "The ba's whom Re is said to call appear as though hovering on waves of light before the standing mummies. . . . The ba's, when summoned by Re, enter into the entourage of the sun, following alongside the other ba's already called into the following of Re" (p. 106). The Egyptian cryptographic text that goes with this picture refers to "the light of Re having entered their corpses. When he calls their ba's, they set out after the (other?) ba's.... Re calls them, and they come forth from the two caverns (?).... When the one who is in his disk calls to you, your ba's ascend towards the one who

created you" (pp. 104–5, Darnell). This picture stresses the importance of the call of light uttered by the sun and its ability to waken the dead to resurrection, which was seen in its ultimate form by the rising sun represented by the hypotenusal mummy of the dawn that rose with its feet at the Sphinx and the tips of its hands at the tops of the Giza pyramids. (*Photo by Robert Temple*)

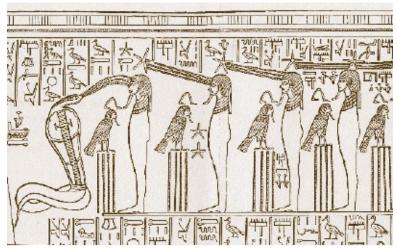

Figure 8.41. This is a drawing of the image seen in figure 8.40. Taken from Alexandre Piankoff, *The Shrines of Tut-Ankh-Amon*, Pantheon, New York, 1955, figure 42, opposite page 128.

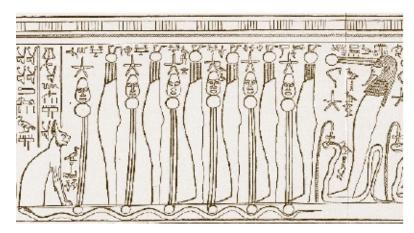

Figure 8.42. This is a drawing of the scene shown in figure 8.43. Taken from Alexandre Piankoff, *The Shrines of Tut-Ankh-Amon*, Pantheon, New York, 1955, figure 42, opposite page 128.

Another hypotenusal Osiris appears on this golden shrine at the golden angle (this time vertical rather than horizontal) in the scene depicted in figures 8.43 and 8.44. At the right of this image in figure 8.43 is a leaning Osiris, standing with his feet in a protective Mehen serpent (Enveloper), and with the light of the sun streaming into his forehead to resurrect him. However, the photo does not encompass the entire scene. In figure 8.44, which extends farther to the right in the scene, we see that there is really a series of six hypotenusal Osirises rising from the dead at the golden angle of resurrection. If one draws a line along the beard, face, and forehead of each figure until it reaches a vertical line that is perpendicular to the base of the scene, one gets a golden angle. Further details are given in the captions. No fewer than seven hypotenusal Osirises being resurrected at the golden angle at the eastern horizon—becoming Horus-in-the-Horizon—are shown on this one golden shrine alone.

Figure 8.43. An image in beaten gold from the Second Shrine of Tutankhamun. At right, the first of a series of Osirises leaning backward at the golden angle is irradiated by light streaming into his forehead (there are other Osirises to the right of him; see figure 8.44). This light, the "word" of the sun who speaks light, revives Osiris and brings about his resurrection, signified also by his leaning backward at the golden angle of resurrection (the golden angle is between him and the vertical plane). He stands in the protective folds of the Mehen serpent, the Enveloper, who keeps him safe while in the netherworld. At far left, a cat representing the eye of the sun presides over six headless entities. These entities are the blessed dead whose heads, now the property of the sun, will be returned to them because they have been just and are to be spared from annihilation and given eternal life. Individual suns stream light down into the headless torsos, and above each head is a star. The heads of the saved and blessed entities are called "those relating to the pupil of the sun's eye." The sun speaks to these entities: "When he calls to them they live . . . by the breath of his mouth do they receive their heads" (John Darnell's translation). It is the light of the sun that is "the breath of the sun's mouth," since the sun's mode of speech is to emit light. It is this breath that streams as light down into the headless mummies. During the third hour of the night, the heads are returned to the blessed dead, and Anubis ties them back on. See also the drawing of this scene in figure 8.42. (*Photo by Robert Temple*)

Also relevant are certain of the wall paintings in the tomb of Rameses VI, of which we have already seen three, the birth of Horus from the mummy of Osiris (figure 8.20), Osiris in his Hidden Chamber (figure 7.7), and the Fifth Hour of the Night with Sokar in his cavern beneath a pyramid topped with a human head (figure 7.8). One other may be seen in figure 7.9. Although the captions of all of these give much necessary information, it is important to put these images in their joint perspective. The arduous journey of the sun god in his boat through the netherworld every night, with its perils and vicissitudes, always culminated in his rising successfully in the east, with the aid of the beetle Khepri, who pushed him over the horizon, often into the welcoming outspread arms of Shu, god of air and sky. But when he did emerge, reborn and resurrected, he did so as a resurrected Osiris who had become a Horus-in-the-Horizon, manifesting himself at the golden angle of resurrection. In figure 8.45, drawn from a painting in the *Book of the Hidden Chamber* on the walls of the tomb of Rameses VI, we see this culmination of the twelfth and final hour of the night, with the dawn breaking and the hypotenusal Osiris transforming himself into Horus-inthe-Horizon.

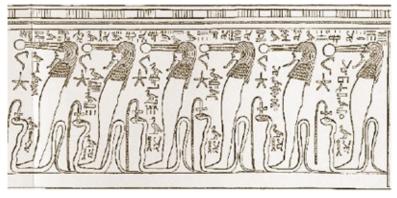

Figure 8.44. This scene from the Second Shrine of Tutankhamun shows six Osiris entities rising from the dead at the golden angle from the horizon at Rostau (Giza). Each is protected at its feet by a guardian Mehen serpent. The first Osiris entity is called

"he of Mehen." The second is called "born of corpse," the third is called "born of members," the fourth is called "begotten one," the fifth is called "one related to going about," and the sixth is called "leaping of corpse." "Leaping" is from the verb *nehep*, to leap. This verb refers to ascension (which was regarded as leaping) from the netherworld, and there were also *nehep* serpents (see one in figure 8.27) that stood up vertically or leaped up, which were friendly and associated with resurrection. These Osiris entities are the blessed dead, who are being revivified in their mummy state by solar disks beaming light into their foreheads. Soon they will rise above the horizon and be reborn. We know they are being resurrected because their bodies constitute hypotenuses of triangles containing golden angles (which are not drawn in the scene, but which had to be used by the draftsmen in constructing the picture). If one draws a line along the beard, face, and forehead of each figure until it reaches a vertical line perpendicular to the base of the scene, one gets a golden angle; and if the hypotenuse is continued to the baseline, a triangle. These blessed dead are therefore mini-Osirises about to be reborn as Horuses. The text specifically locates this scene at Giza by saying: "You will fly up from Rosetau by day, in exultation every day; you will go about on earth daily" (translation by John Darnell, page 120. Ref. also Darnell plate 10, A Scene 3). Drawing taken from Alexandre Piankoff, *The Shrines of Tut-Ankh-Amon*, Pantheon, New York, 1955, figure 42, opposite page 128.

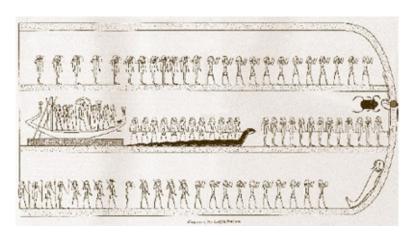

Figure 8.45. The final and twelfth hour of the sun's journey through the netherworld, which culminates in the sun's rising at the eastern horizon (at right). In the middle register at the left, the ba of the sun is in the last stage of its journey over the water (represented by the wavy lines contained in what looks like a pedestal beneath the boat). The huge serpent in the center of the picture is called the Nau serpent, who is a protective deity. He is described in the text as being 1,300 cubits (2,332 feet) long, and "he moves toward the birth of the god" (i.e., the rising of the sun as Osiris/Horus-in-the-Horizon). It is his job to clear the way for the sun god. Nau also has the meaning of Divine Path, and for some unknown reason, the Nau serpent was associated with the twenty-third day of each lunar month. He is clearly astronomical, but we do not yet fully understand his significance, or what the 1,300 cubits refers to. In the text he is also called the Great Ka, Life of the Gods. The Khepri beetle, symbol of the rising sun, is at the horizon, presiding over the red sun of the dawn, who is being welcomed by the head and outspread arms of Shu, god of the air and sky. The hypotenusal Osiris, who is always associated with resurrection and the revived sun and has now become Horusin-the-Horizon, is at bottom right, at a golden angle (his head making a golden angle with the vertical plane). Directly in front of the hypotenusal Osiris as Horus is a procession of ten sun worshippers, followed by four priests, behind whom is the Nehep serpent standing on his tail as a symbol of resurrection, spewing a stream of light from his mouth, and with the ankh, symbol of life, beneath his jaw. Twelve sun worshippers form the right side of the procession in the top register. In the middle register, the figures are the towers of the solar boat. (From Alexandre Piankoff, The Tomb of Rameses VI, Pantheon Books, New York, 1954, figure 87, opposite page 312)

The archetypal setting for all of this was at Giza. That was the Place of the Golden Angles, the Place of Resurrection. It was truly Golden Giza, where eternal life awaited the blessed dead. In this setting, presided over by the guardian Anubis, carved as the largest statue in the world, the resurrected sun flashed on the gold-plated tips of the three Giza pyramids, and the beams of light struck the tip of the Pyramid of Chephren literally at a golden angle through the air. All the key monuments were knitted together tightly by overlapping and interconnecting golden angles in a maze so complex and so unobvious to the uninitiated that it has escaped detection until now, approximately 4,500 years after its pattern was last known, recognized, and understood.

Figure 8.46. In the center of this picture in beaten gold from the Second Shrine of Tutankhamun lie two mummies in their sarcophagi. They are both encircled by the protective and friendly netherworld serpent named Tepi, "he with the head," who is always shown with a human head. It is his job to keep the mummies safe and, because he emits light, to provide illumination in the darkness. He is the same human-headed serpent as the one depicted in figure 8.6, a scene from the tomb of Rameses III. The top mummy is labeled "he of the sarcophagus" and represents the dead Osiris wearing the white crown of Upper Egypt; he also represents the corpse of the sun during the night hours when he is in the netherworld. Below him is a mummy believed (on the basis of similar illustrations elsewhere) to be that of the netherworld Horus in the process of emerging from the dead Osiris just prior to the sunrise, when he will be represented as the hypotenuse of the golden triangle who leaps above the horizon and becomes Horus-in-the-Horizon, particularly at Giza. To the right of the encircled mummies is a strange container known as the Chest of Re. It contains secret things. The arms and four hands are a cryptographic inscription that in addition gives a double meaning. Crytographically, the hieroglyphs can be read "chest," but the four hands also stand symbolically for "the limbs of Osiris" that lie concealed in the mysterious chest. Although I have solved the mystery of what the ancient Egyptians were really referring to by their myth of "the limbs of Osiris" and have explained this at length in my study of the Temple of Seti I and the Osireion at Abydos, with physical evidence to make it clear, the explanation is far too lengthy for summary here. Beneath them, and seen more clearly in the accompanying drawn version of this picture in figure 8.47, the ram's head of the netherworld form of the ba (spiritual force) of the sun is seen rising out of the earth, which represents the imminent sunrise. When he rises he will be "the great corpse which is in the horizon, the secret divine corpse" (John Darnell, pp. 90–93), who is shown as the hypotenusal mummy rising at Giza. (*Photo by Robert Temple*)

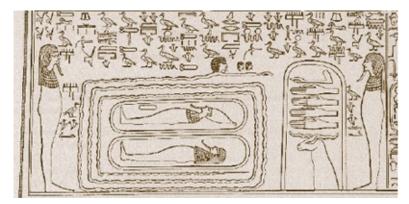

Figure 8.47. This is a drawing of the image seen in figure 8.46. Taken from Alexandre Piankoff, *The Shrines of Tut-Ankh-Amon*, Pantheon, New York, 1955, figure 41, opposite page 120.

Figure 8.48. A magnificent Old Kingdom carving of a solar ram, who has risen from the horizon and is triumphant in the sky. (Object in the Egyptian Museum at Cairo; photo by Robert Temple)

We now know that at Giza there are multiple esoteric connections between the key points of the main structures, which define their size, shape, and location, based on lines drawn by some planner on a map and then carried out on the ground by surveyors and construction engineers.

The location and dimensions of the Sphinx are therefore not accidental. They and the Great Pyramid, the Pyramid of Chephren, and the Pyramid of Mycerinus are all mutually defined. All took their sizes and positions from each other, and all were part of a simultaneous plan. Giza is a unity.

Truly this plan is magnificent and beautiful.

Now perhaps we may at last have a true understanding of the Great Sphinx of Giza. It was originally a gigantic statue of the guardian Anubis, crouching at the entrance to the Giza Plateau. It was an island surrounded by a moat filling the surviving Sphinx Pit, most commonly known in ancient times as the Jackal Lake, which was filled with water from the Nile inundation and was also topped up by water carried down a specially constructed drain to catch any rain that fell higher up the plateau. Sacred ceremonies took place in, on, and around this moat; they are described often in the Pyramid Texts and later texts as well. During the century and a half of chaos, floods, drought, and famine of the terrible time known as the First Intermediate Period, when the government collapsed and mobs ran amok smashing everything in their rage (following the Sixth Dynasty, which was the end of the Old Kingdom period), the head of Anubis must have been drastically mutilated. We know that during this period the statues were smashed in the adjoining Valley Temple, so it stands to reason that rampaging mobs would also smash the head of Anubis at the same time.

When order returned under the Middle Kingdom and the Twelfth Dynasty was established, and an attempt was made to reconstitute Egyptian civilization (though the art of building stone pyramids could never be recovered and was lost forever), the third king of that dynasty took an interest in the mutilated statue of Anubis. That king was Pharaoh Amenemhet II. Because the head of Anubis was ruined beyond repair, he had a new and smaller head carved out of the neck. That head was a human head, and its face was his own. He was clearly not a man who suffered from excessive modesty or lack of feelings of self-worth.

By the time the New Kingdom came along centuries later, after yet another era, known as the Second Intermediate Period, a young son of the king was out hunting on horseback on the deserted Giza Plateau,

which was largely abandoned and full of wildlife, and he became tired and looked for some shade in which he might rest. He did so in the shade afforded by the head of Amenemhet II, which was sticking up out of the sand. But of course no one knew that the head was that of Amenemhet II, because no one remembered Amenemhet II any longer, much less what he had looked like. The young man assumed that this was the original head of a gigantic buried statue, traces of the back of which were also visible. This young man fell asleep and had a powerful dream. In the dream, the statue spoke to him and said that if he would clear it of sand and show his piety, the god of that statue would make him king of Egypt. (Being a younger son, this was not expected to happen to him.) We do not know how much truth there is in this story, but it is what the young man ordered to be carved in stone and inscribed on the famous Dream Stela between the Sphinx's paws after he had cleared it of sand. That Dream Stela still survives (see figures 3.3, 3.5, 3.7, and 3.8). And the young man did indeed become king of Egypt, the pharaoh whom we call Thutmosis IV, or Thothmes IV. The Dream Stela may largely have been propaganda intended to legitimize his succession, but that doesn't really matter to us anymore, as he is not around for us to complain about his rule or misrule, whichever was the case.

It never crossed the mind of the future Thutmosis IV that the statue that he cleared of sand was not the original statue in its entirety, and that its head had been remodeled. He strapped a stone royal beard onto the face, drilled a hole in the top of the head into which he inserted a pole with banners, painted the statue in garish colors, hung ornamental collars around its neck, and promoted it as an idol to be visited and worshipped. The altar for doing this was conveniently placed in front of his own dedicatory Dream Stela. Thus, this idol was as much a cult of himself as it was of the spirit of the statue. It was a way of celebrating his pharaohship. He claimed that the body was that of a lion. Even if he noticed that it did not really look like one, he chose to overlook that fact, because the lion was a royal beast, and he wanted it to be a lion. So everybody believed in the Emperor's New Clothes, and they still do.

It is amazing how effective propaganda can be.

But what we have needed to recapture is the true purpose, origin, and nature of the Sphinx of Giza. In doing so, we have honored Maāt, Cosmic Order. We can now grasp something that had seemed lost to us forever, the living soul of the Age of Giza. May it bless us in our future endeavors.

# Accounts of the Sphinx from Roman Times to 1837

# ACCOUNTS OF THE SPHINX FROM ROMAN TIMES TO 1798

The following extracts appear in chronological order and are translated when necessary into English—those from French by Olivia Temple and those from German by myself. The notes in brackets within and following the extracts are by me as well.

#### PLINY (1ST CENTURY AD)

Natural History, Book 36, Chapter 17
Translated by D. E. Eichholz, Loeb Classical Library series, vol. X of Pliny, Harvard University Press, USA, 1971

# Page 61

In front of them [the pyramids] is the Sphinx, which deserves to be described even more than they, and yet the Egyptians have passed it over in silence. The inhabitants of the region regard it as a deity. They are of the opinion that a King Harmais [corruption of the Greek Harmachis; other texts of Pliny say Amasis] is buried inside it and try to make out that it was brought to the spot: it is in fact carefully fashioned from the native rock. The face of the monstrous creature is painted with ruddle [i.e., painted red] as a sign of reverence. The circumference of the head when measured across the forehead amounts to 102 feet, the length is 243 feet, and the height from the paunch to the top of the asp [uraeus] on its head is 61.5 feet.

[Pliny is the only classical author to mention the Sphinx, apart from the following indirect reference by the Roman poet Lucan. The Sphinx is not mentioned by Herodotus, Diodorus Siculus, Strabo, or any others.]

# LUCAN (1ST CENTURY AD)

*Pharsalia*, Book IX, 156 Translated by H. T. Riley, Bohn's Classical Library, London 1890

# Page 344

Dragged forth from the sepulchres of the pyramids, shall not Amasis and the other kings float for me upon the stream of the Nile? For thee unburied, Magnus [Pompey], let all the sepulchres pay the

penalty . . .

[There is general agreement among those few scholars who have noticed this line in Lucan's epic poem about the civil war between Pompey and Julius Caesar that the reference to Amasis is to the tradition in Roman literature at that time that he had been buried at the Sphinx. (There was never any tradition that Amasis had been buried in any of the pyramids themselves.) Riley, the translator, has even added a footnote to this effect (page 344, note 4).]

# ABD AL-LATÏF AL- BAGHDĀDI (1220 AD)

Relation de l'Égypte French translation of "Abd-Allatif" from the Arabic by Silvestre de Sacy (Paris: Treuttel et Würtz, 1810)

Pages 179-80

A little more than a bowshot from these pyramids, one sees the colossal figure of a head and a neck, which come out of the ground. This figure is called *Abou'lhaul*; and it is said that the body to which this head belongs is buried under the ground. In judging the dimensions of the body from those of the head, it ought to be 70 cubits or more in length. One sees on the figure a reddish tint and a red varnish, which has a vivid freshness. This figure is very beautiful, and its mouth has an air of grace and beauty. One could say it smiles graciously.

When a perceptive man asked me what excited my admiration most of all the things that I had seen in Egypt, I said to him that it was the precision of the proportions in the head of the Sphinx. In effect, one remarks between the different parts of this head, for example the nose, the eyes and the ears, the same proportions which one sees in the works of nature. Thus it is that the nose of a child matches its size and it is in proportion with the rest of its body in such a way that if it belonged to the face of a man it would be a deformity. The nose of a man transposed onto the face of a child would disfigure it. It is the same with all the other parts of its head: there aren't any parts of it that should not have a certain shape and certain dimensions to be in proportion with such a figure. And if these proportions are not respected, the figure is spoilt. So it is astonishing that in such a huge figure, the sculptor had been able to conserve the correct proportions of all the parts, while nature does not provide any similar example of such huge size, nor anything that could be compared to it.

[Note: The nose of the Sphinx had not yet been disfigured at this date, and the face was still intact.]

Page 225 (footnote 38 of de Sacy)

I have not discoursed further upon the Sphinx, nor the extensive mutilations that have been inflicted on it since the time of Abd-allatif. One can see these details in the notes and explanations put together by Monsieur [Louis] Langlès in his edition of the Voyage of [Friderik] Norden [see under date 1757, following, the extract from *Travels in Egypt and Nubia* by Friderik Norden; the 1797/98 French editions of Norden's book incorporate these notes referred to by de Sacy, but they were not in the 1757 French edition]: but I cannot refrain from quoting two modern writers whose evidence confirms after six centuries the account of our author: "This monstrous statue is truly colossal, says Monsieur Grobert, . . . it has been painted yellow, and the color has been preserved until today in the parts which are not damaged."

The other passage is even more important in its details, and by the name of the author who is deemed unimpeachable in this subject. This is Monsieur Denon, and he explains thus:

[This passage is translated under "Denon."]

# ABD AL-LATĪF AL-BAGHDĀDI (1220)

Modern English translation of above de Sacy passage: *The Eastern Key: Kitāb al-Ifādah wa'l-I'tibār* Translated by Kamal Hafuth Zand and John A. and Ivy E. Videan (London: Allen and Unwin, 1965)

Pages 123-25

At little more than a bowshot from these pyramids is a colossal figure of a head and neck projecting from the earth. The name of this is *Abu'l haul* (Sphinx) and the body to which the head pertains is said to be buried under the earth. To judge, from [on the basis of ] the dimensions of the head, of those of the body, its length must be more than 70 cubits. On the face is a reddish tint, and a red varnish as bright as if freshly applied. The face is remarkably handsome, and the mouth expresses much grace and beauty: one might fancy it smiling gracefully.

A sensible man enquiring of me as to what, of all I had seen in Egypt, had most excited my admiration, I answered: "The nicety of proportion in the head of the Sphinx." In fact, between the different parts of this head, the nose, for example, the eyes, and the ears, the same proportion is remarked as is observed by nature in her works. Thus, the nose of a child is suitable to its stature, and proportioned to the rest of its frame, while if it belonged to the face of a full-grown man it would be reckoned a deformity. The nose of a grown man on the visage of a child would equally be a disfigurement. The same holds good with respect to all the other members. There are none but should have a certain form and dimension in order to bear relation to such and such a face, and where these proportions are not observed, the face is spoiled. Hence the wonder that in a face of such colossal size the sculptor should have been able to preserve the exact proportion of every part, seeing that nature presented him with no model of a similar colossus or any at all comparable.

# TAQIYYU 'L-DIN AL-MAQRIZI (1378 OR 1379)

This passage is taken from the French translation in the Notes of Louis Langlès, *Voyage d'Égypte et de Nubie par Fréderic-Louis [Friderik] Norden*, new edition (Paris: 1798, vol. III), pages 338–39

The blessed Sheikh Mohammed Ssa'im el-Deher, of the Sufi Order from the Monastery of el-Salehhyeh, devised the plan to destroy some of the practices contrary to the law of Allah. We have seen this saintly person go to the pyramids, mutilate the figure of the Sphinx, and dispose of the pieces of it. This figure remains in this state up until today, and since that era the sands inundate the territory of Giza. The inhabitants attribute this scourge [of the sand] to the mutilation of the Sphinx.

# BERNHARD VON BREYDENBACH (1483)

Les Saintes pérégrinations de Bernard de Breydenbach, 1483. Texte et Traduction Annoté, par le Père F. Larrivaz, S. J., Extraits Relatifsá l'Égypte Suivant l'Édition de 1490 (Cairo: Imprimerie nationale, 1904)

Near these pyramids the great idol of Isis [the Sphinx], previously venerated by the Egyptians, is still standing. Beyond, one also sees some vast ancient ruins; previously, the celebrated and mighty capital of Egypt, which had a hundred gates, was also situated there, and it was the birthplace of Saint Maurice and of the Theban Legion.

[Here he confuses Memphis near Giza with the later capital of Thebes in Upper Egypt, which was said to have had "a hundred gates."]

# Voyages en Égypte

The French Institute of Archaeology at Cairo between 1970 and 1988 published twenty-five volumes (some in several parts) of early travelers' descriptions of Egypt, dating from 1482 to the time of Napoleon. Some volumes contain several travelers' writings. This admirable series is entitled *Voyages en Égypte*, and was published in Paris. Olivia and I have excerpted every description of the Sphinx appearing in these volumes and she then translated them all from French. This was often difficult, as the language was old-fashioned, and many obsolete words occurred. Some of the passages are translations into French from other languages.

JOOS VAN GHISTELE (1482–1483) Translated from volume 16 of the series *Voyages en Égypte* (1976)

Page 83

Behind these pyramids is found a statue [the Sphinx] of which the head is so large that 4 spans [brasses] are insufficient to encompass it. This statue has the appearance of a human being as far as the shoulders, but from there on it reveals the form of a serpent [he could only see the top of the back, which looked like a serpent], of which the tail is a good 50 spans in length. The whole statue is carved from one single piece of rock. In the vicinity people recount that this head had the habit of speaking, at the time of idolatry, after the fashion of other false gods. One day in those times, a man went there to make some sacrifices; he asked of the Idol what was going to happen to him, and the head replied to him that he would become King and master of Egypt if he wanted to follow its counsels. Thereupon, the man replied that he would follow them, and it happened that this man became King of Egypt as he had been told he would by the head. A little while after his coronation, he returned to the place where the head was, which he decapitated with an ax, saying: "It's all very well that you have given me counsel so that I can secure Egypt; but from today on, you will not give any more counsel to anyone." And so it is that since then the head rests upon the ground up until our own time.

[Note: This amazing folklore survival of a true story over the course of three thousand years has been discussed at length in chapter 3.

#### FELIX FABRI (1483)

Translated from volume 14 of the series *Voyages en Égypte* (1975)

Pages 452-54

# The Sphinx of Giza: Idol of Isis?

Near the pyramids we saw a huge stone idol which had the form of a woman, and we had no doubt that it was a monument dedicated to Isis. Daughter of the Greek Prometheus, of a unique beauty, she had been loved and pursued by the adulterous Jupiter. Having fled far away from her father because of the crime perpetrated, and with the assistance of Jupiter, she made her way to Egypt with a naval fleet, and after a series of wars, she submitted to Egypt . . .

Page 455

#### A Misshapen Rock Near the Sphinx of Giza

Near the idol of Isis, lies a kind of misshapen rock which—it is said—once formed the figure of an ox, of Osiris or of Apis. On the death of Osiris, legend says, his heart emigrated into an ox, which is the reason that the Egyptians worship the ox. As for Isis, his wife, having reassembled the pieces of his cut up body, she deposited them in a wooden ox, re-covered it with bovine skin and left it to the veneration of the people. With the passing of time, the wooden idol rotted and the Egyptians carved an enormous rock and consecrated it to Osiris.

Page 456

#### A Small Lake with Miraculous Water

On the other side of the pyramids, not far from the Idol of Isis [the Sphinx] there is a small lake, more memorable for its miraculous property than the abundance of its water. Once a year, for one month, its water changes into blood—a fact of which the Saracens attribute to a perpetual reminder of the first wound by which the water and the rivers of Egypt were changed into blood as mentioned in Exodus 7.

[Note: Exodus 7: 17–25, in The New English Bible (1970)]:

[Moses said to the Egyptians at the command of the Lord]: "... so now the Lord says, 'By this you shall know that I am the Lord.' With this rod that I have in my hand, I shall now strike the Nile and it will be changed into blood. The fish will die and the river will stink, and the Egyptians will be unable to drink water from the Nile." The Lord then told Moses to say to Aaron, "Take your staff and stretch your hand out over the waters of Egypt, its rivers and its streams, and over every pool and cistern, to turn them into blood. There shall be blood throughout the whole of Egypt, blood even in their wooden bowls and jars of stone." So Moses and Aaron did as the Lord had commanded. He lifted up his staff and struck the water of the Nile in the sight of Pharaoh and his courtiers, and all the water was changed into blood. The fish died and the river stank, and the Egyptians could not drink the water from the Nile. There was blood everywhere in Egypt. But the Egyptian magicians did the same thing by their spells; and still Pharaoh remained obstinate, as the Lord had foretold, and did not listen to Moses and Aaron. He turned away, went into his house and dismissed the matter from his mind. Then the Egyptians all dug for drinking water round about the river, because they could not drink from the waters of the Nile itself. This lasted for seven days from the time when the Lord struck the Nile.]

#### PIERRE BELON DU MANS (1547)

Translated from volume 1 of the series *Voyages en Égypte* (1970)

Page 113a (no modern pagination; pagination derived from the original)

Finally, having come up to the village of Busiris, where the water of the Nile has broken the arches of the stone bridge, it is necessary to go by boat. And after the village of Busiris, there is a long causeway, which goes on to terminate at the desert of the pyramids. [The causeway to which he refers culminated, as one approached the Giza Plateau, in the Cheops Causeway, leading up to the Great Pyramid. In those days it was still intact, and the stones had not yet been carried away or built over. Today, not a stone remains. Old engravings show this causeway intact in the seventeenth century, and portions of it intact well into the nineteenth century.]

[This is the Busiris near the Sphinx, not the Busiris that was in the north of Egypt, in the Delta region. The Gizan Busiris was called Djedu ("ghosts") by the ancient Egyptians.]

#### Page 113b

Then we came to pass the dike of Busiris, which has been broken in one place, where the water of the Nile has formed a lake (of which the Greeks have taken the occasion to invent the fables of the waters of their Rivers Lethe and Styx: for the embalmed bodies, which were carried to the sepulchre, passed by boat across the said lake, which has completely overflowed and broken the causeway). Those who had ascended well up [the dike] did not have any difficulty in fording across, following the guides, but the others not so high up had to wait for a boat. Nevertheless, some who had stripped their clothes off led the others, mounted, by the halter, enabling them to pass through the water, which was up to their armpits.

# Page 115b

Thus we come to the Sphinx or Andro-Sphinx, of which the ancients have spoken so much, which is still entire in the above-mentioned sterile plain with the pyramids. It seems well not to pass it by without saying a little something about it.

Concerning the Great Colossus named by Herodotus Andro-Sphinx and by Pliny The Sphinx, Which is a Stone Sculpture in front of the Pyramids

Having well considered the great stone head, which is adjacent to the water of the Nile a little way below the [level of the] Great Pyramid [a remarkable confirmation, if any were needed, of the points made in chapter 6 of this book], we had occasion to admire the works of the Egyptians. And although Pliny had very much exaggerated the size of the pyramids, nevertheless, he was more reasonable in describing the colossus of the Sphinx, which is to the right of the Great Pyramid towards the east.

We do not want to linger too long on the description of the Sphinx, for truly all that has been depicted and written of this creature, from the Ethiopians to the Egyptians, is fable. . . .

### Page 116a

This stone sits on a cubic shape, which is only a large sculpted face looking toward Cairo. Its proportions of face, nose, eyes, mouth, chest, chin, and other parts are so well retained that we cannot deny that it is a very grand creation. It doesn't have any similarity to other sculptures of sphinxes. . . .

#### Page 116b

But this stone of which we speak is still the greatest marvel, for being massively huge, it has a height of 63 feet. Pliny gave it 143 feet in length. . . . It is the grandeur and sublimity of this colossus that is no less a marvel than a great obelisk. We like to maintain that the Romans never made anything from a huge mass of stone which could compare in sublimity and magnificence to the work of a pyramid, an obelisk, or to the Sphinx of which we speak. . . .

[It must be noted that at this time, as units of measurement, French feet were considerably shorter than English feet, so allowance must be made for this in some of these early accounts. On the other hand, Belon errs in saying that Pliny gave a length of 143 feet for the Sphinx, when it was really given by him as 243 feet, and the Pliny measurements seem to be transposed into English feet rather than French feet. Probably the safest thing to do with all the early accounts is to ignore the many measurements that are given of the Sphinx as being irrelevant, since we now know all the true measurements anyway.]

#### Page 117a

It remains now that we speak of whence the Sphinx has come to the Egyptians: It is that during the sign of Leo and Virgo [he is unaware that Leo and Virgo did not exist to the ancient Egyptians prior to the third century BC], the Nile inundates the land of Egypt, and the Egyptians, wanting to signify their riches [the crops from the rich soil deposited by this inundation], created a sculpted monster, which is a virgin in front and has the body of a lion, and bears the name of the Sphinx, and because it is something made to please, one thus sees this [image] also in [diverse] sculptures. Witness the abovementioned great head of the Sphinx. . . .

# ANDRÉ THEVET (1552)

Translated from volume 24 of the series *Voyages en Égypte* (1984)

# Pages 190–93

Do not expect to see the whole base and foundation of these pyramids, which are in this sandy locality. The sands have covered a good part of them despite the fact that they equal the highest mountains of Egypt in their elevation. [At that time, large mounds of sand-covered rubbish lay against the sides of the pyramids, from the time when they were stripped of their casing stones. Today, all of this has been cleared away.] And this has been seen even more so with the colossi that one calls sphinxes (on account of the monstrous figure and variety that they have), which are beginning to be buried in the piles of sand blown about by the wind.

It is true that I cannot be persuaded, that the colossus which we see there today is not one of these sphinxes which one guesses to be the tomb of some Egyptian king. It represents nothing more than a monster, in that it is made like a man's head, marvelously huge, a body without shape, and of hard

stone. . . . Some say that Isis raised the monument after the loss of her friend [Osiris], beating her breast on account of his death. Its head is huge like a tower, being 200 paces broad and about a hundred long. . . . Pliny mistakenly spoke of this Sphinx or Colossus, saying it was more admirable and remarkable than all the pyramids: this comparison is about as true in terms of grandeur and size as would be that of comparing a rat to an elephant. And if he had seen it and studied it as closely as I did, he [Pliny] would not have written such nonsense, unless it was the translator and commentator of my own time [Antoine du Pinet, translator of the French version of Pliny published in Lyon in 1562], who mocks the reader by saying that it has a large head, the wings of a bird, and that the rest of the body resembles a dog. This description is also mistaken in that there are no wings, no body, nor any resemblance at all that I know of, and I have seen it nine times in three years.

[The "wings" mentioned by du Pinet in his marginal note to his translation of Pliny may derive from descriptions of the *nemes* headdress, which has sometimes been called winged because of the folds extending to either side of the head. Thevet points out that since the Sphinx was buried in sand up to its shoulders, it was impossible to say in his and du Pinet's time what its body looked like, and hence it had no discernible resemblance to anything.]

#### CHRISTOPHER FUERER VON HAIMENDORFF (1565)

Reis-Beschreibung, in Egypten, Arabien, Palästinam, Syrien, etc. (Nuremberg: 1646)

Pages 59-60

#### A Large Sphinx Which Was Used for Giving Oracles

In front of the pyramids, in the direction of the city of Cairo, stands a very large Sphinx cut out of the rock, so much covered by wind-blown sand on its lower part that only the head, breast, and back protrude. The head is no less than 53 of my paces [meiner Schritt] in circumference [he could walk around it] and similarly also 53 paces tall. An immensely large creature. It has on its right side in its flank a quadrangular hole [viereckicht Loch, which could mean either a square or rectangular hole] through which, as we were informed, in olden days one could go inside and could ascend into the head. Inside there the priests spoke, which the Egyptians took for oracles. Nowadays, this hole is mostly collapsed and filled with sand by the wind. [It is unlikely that this is eyewitness evidence that there was an entrance into the Sphinx behind the "cupola," which now sits up against the right side of the Sphinx, since it is difficult to believe that the Sphinx was cleared down to bedrock for it to be seen at this period when, after all, Haimendorff could walk around the head. This reference must therefore be to the same square hole in the Sphinx's back reported by many others, as discussed in chapter 2 of my main text. Because the back was only partially exposed, "its right side" as seen by Haimendorff may have been in the center, structurally speaking, but to the right in terms of what was actually exposed to his view, suggesting that the sand had risen higher at this time on the south side than on the north side, which is the case in many of the old photos in this book. The only other alternative would be to suggest that there had been a partial clearance of the Sphinx in the sixteenth century, though Castela said that in 1600-1601 he could only see a head and shoulders, which is confirmed by Sandys in 1611. The fact that Haimendorff mentions the hole immediately after saying that the Sphinx was "an immensely large creature" suggests that the hole may have been seen only after going a considerable distance along the back to reach it.]

#### JOHANN HELFFRICH (1565)

Kurzer und Warhafftiger Bericht/ von der Reis aus Venedig nach Ieursalem/von dannen in Aegypten/auff den Berg Sinai, Allcair/ Alexandria/ und Folgends Widerumb gen Venedig

[A Short and True Account of the Journey from Venice to Jerusalem, from thence into Egypt, to Mount Sinai, to al-Cairo, Alexandria, and Afterward Returning to Venice; unpaginated, but organized sequentially by date as in a diary (the year of the journey being 1565)] (Leipzig: 1579)

December 13 [1565; "Den Dreyzehenden December"]

The following day we left early and several of us rode to the place where the pyramids stand. As we approached it, we first encountered a huge standing head cut out of stone, which rose very high, as shown in this figure. [He refers to a crude woodcut opposite, showing a woman's head and torso with two breasts, and hair descending to either side to the extent of the Sphinx's lappets, which is shown protruding from the sand directly below the breasts.]

This head is the height of three men and stands straight up from a neck, it is 8 fathoms [about 50 feet] in circumference, and from ancient times has been called Imago Isidis, that is, the effigy of the goddess Isidis. This Isis of which the image has the name has also been called Io and is a daughter of the King Inachos in Greece, which king in Egypt is called Osiris, where he is her husband. There she is called Isis, who, after she died, was considered a goddess, and this image was set up to honor her. The local inhabitants worship it and honor it as a goddess. They are also in the habit of offering a sacrifice of a goose at the usual time, which offering they call the Isiaca. [The noun spelled in the original, *eine Ganz*, is a sixteenth-century form of *Gans*, "goose."] Concerning this, consult Juvenal, *Satires*, 6: *Si candida iusserit Io*, and recall Lucian's *Dialogues* in three volumes. [No reference is given, so we do not know to which Dialogue by Lucian he is referring. His reference to the Sixth Satire of the Roman poet Juvenal is to lines 526–41, "if the white Io shall so order," Io here being identified with Isis, and a mention by Juvenal that a fat goose was offered to Osiris by a priest dressed as Anubis. Juvenal spoke of Isis giving a command "by the voice of the Goddess herself," presumably referring to the oracular pronouncements issuing from the Sphinx.]

This image [the statue] is entirely hollow on the inside, and one can enter it underground from a distance by means of a narrow passage made of stone, through which one can pass secretly. By means of this passage, the heathen priests entered the head and spoke to the people, making announcements by the babbling of the head, or else the effigy did this by its own means.

Hard by this head are the three pyramids just mentioned. . . .

# JEAN PALERNE (1581)

Translated from volume 2 of the series *Voyages en Égypte* (1971)

Page 109

A little to the right of the Great Pyramid is a massive head looking toward Cairo, not a little wonderful, for apart from the fact that it is made from a huge piece of marble lying on its base, in size it has a circumference of around 100 feet, and in height taken from the chin toward the top of the head, some 60 feet. Some people take it to be a monstrosity, having the face of a man and the body of a lion. As regards to the body that it has, it is all eaten away and corroded, appearing nevertheless to have traces of color on the face, with ears of huge proportion; the remains are well enough proportioned.

As has been said, one knows that the Egyptians wished to signify the wealth and fertility of the land that the inundation of the Nile produced, while the sun was in the signs of Leo and Virgo represented by a monster having the front half of a virgin and the back end of a lion: and they called it Sphinx: nevertheless, it had the face of a man, not of a woman.

Other people say that this head served in the past as an oracle. And happy was he who could be buried nearby. This is made apparent by the large number of sepulchres that are round about here . . .

#### PROSPER ALPIN/ALPINUS (1581–1584)

From his Histoire Naturelle de L'Égypte

Translated from volume 20 of the series *Voyages en Égypte* (1979); the whole work appears in five parts from 1979 to 1980 and includes volumes 21 and 22 of the series

Part I, page 68:

Chapter VI: "The Pyramids and the Great Colossus Named Sphinx," pages 58–68.

### The Sphinx

But last of all we come to that great colossus called Sphinx, near to the first pyramid and made from an enormous monolith. This massive rock is made of marble [i.e., limestone. Travelers have often mistaken the nature of Egyptian stone; also, they have often gotten the descriptions wrong of stones that are less common in Europe, such as rose granite. The Sphinx is made of limestone, since it is a rock of the Plateau of Giza recut and finished by man.] It presents an immense and very large face, looking towards Cairo and sculpted in every way with great competency. That is to say, its chin, its mouth, its nose, its eyes, its brow and its ears seem to be cut with a profound knowledge of the art of sculpture. There does not appear to be in the stone any opening by which one could go inside, but it is likely, as we have said of it, that one entered into the colossus from the Great Pyramid nearby. And, since the Sphinx on occasion gave [oracular] responses, it is likely that inside it contains some empty parts into which the priests would go in order to be able to reply on its behalf.

# Page 60

But now we will talk about what we saw inside the Great Pyramid. For no one, it seems to me, has properly described the interior. Until 1584, this pyramid only had one door by which you could enter. But, this past year [1583/1584], the Bassa [Pasha] Ibrahim, the deputy king of Egypt, urged by curiosity, or rather by an African sorcerer [or witch doctor], that a valuable treasure was hidden in the pyramid, ordered that the entrance, which was very narrow and made access difficult, be enlarged —by cutting into the pyramid so that a man can now go inside without stooping. The Bassa even, at first, decided to hollow out a shaft inside the pyramid and to fill it with gunpowder to completely destroy the monument. But he changed his mind at the advice of George Hemi, now the Illustrious Consul of Venice (for, I say, in doing so he would have greatly endangered the whole town).

# Page 61

But now I speak of the entrance to this pyramid. I have said then, that the pyramid only had a means of entry by a single door, at the base, in the middle of one of the sides. This entrance gave access to nothing important. So, in the stone wall of the pyramid, nearly at the base, in the middle of one side,

there is a hole, about 5 paces long, similar to a section of a pyramid with four sides [he is referring to the angled arch above this entrance], with a more spacious opening and larger outside, but narrow and rounded on the inside. At first very large, this opening gets smaller by slow degrees and comes to an end with a long and steep passage. Thus, the opening of this hole, on the interior, becomes narrow and confined, to the point where a man stretched out on the ground on his stomach and crawling like a snake has difficulty entering. [This is the Descending Passage, which at that time was still nearly blocked by sand and rubbish at the bottom.]

#### **Inside (The Interior)**

Once inside, one comes across a large space to the right, from which there is a shaft, quite narrow and almost filled with sand and stones. [This is the entrance to the ascending "well shaft," which is found near the bottom of the Descending Passage. The sand and stones were finally cleared from above by Captain Caviglia in 1817.] It is certainly of this well that Pliny himself, among the ancient writers, speaks.

[Pliny speaks of the pyramids more with irony than admiration. He mentions this well: "86 cubits, which, one thinks, received water from a river . . ."]

Page 63

#### The Well

But we think that we should not pass by in silence another peculiarity which also excites admiration on account of its superiority; it concerns a well which we encountered after our entrance into the pyramid. We found that it was at least 70 paces deep and did not contain any water. And I shall tell you how we were able to verify this.

From a mountain called Liban had come to Egypt the reverend brother Paul Bigi, (*janensis*, as I have heard tell) [indicating his place of origin] from the order of Preaching Friars, a man who was very knowledgeable in all kinds of sciences, specializing in mathematics and mechanics: with the help of bronze clocks, he made a sphere by means of which one could observe with great exactitude all the movements of all the celestial bodies and especially the planets. [Presumably, this was an orrery]. With the same competency, he made in Cairo, for Assan [Hassan], the deputy king of Egypt, a little gold boat which, moved by clockwork, accomplished by itself all the movement essential for navigation. As soon as it was finished he showed it to us: on its own it moved forward, backward, and around; the sails unfolded and folded up again, the anchors were raised, the bronze missiles were automatically fired; one heard the sound of trumpets and all the things that vessels usually do.

Such was the intelligence of this man, that he so closely examined everything with more care than other people. One day, he happened to come with us to look at the pyramids, and once inside the large one [the Great Pyramid] he examined with much care and in great detail what he found there. As a result he came to the idea that the pyramid went deep into the earth before it was raised above the surface, and he suspected that the well had not been made for receiving water but rather to serve as a means of access toward the base of the pyramid.

To verify his hypothesis, he employed some local people, without regard for the expense, so that they could clear the entrance to the pit, filled with earth and stones, and free the passageway [the Descending Passage]. After that, with a long rope introduced into the well, he descended [from the Grand Gallery], with ourselves and some other people for about 70 paces, and with ease, saw that the

cavity of the well had, here and there, some jutting stones, like cornices, which made the descent easy and without danger. Once we were about 70 paces down (as we said before), we found two square passages joining again, in the empty space where the well converges, those which we had encountered in the upper parts of the pyramid: one leading to the stone Sphinx and the other to the second pyramid, the one which has no way of entering. [At that time there was no known exterior opening into the Chephren Pyramid; it was opened in 1818 by Belzoni.] We would have got through to these monuments if we had not found the passages obstructed by stones that had fallen and if we had not believed that there were similar subsidences ahead.

Thus, this well had not been hollowed beforehand to provide the necessary water for construction, as [Pierre] Belon had mistakenly believed. It had been constructed to make possible a way to go and see the great stone Sphinx which had been built not far from the pyramid, as well as the second pyramid called Sepulchre of the Queen [Chephren's Pyramid], to which there is no exterior access. This great depth of well is even mentioned by Pliny, who gives it 86 cubits. Relying on his evidence, Paul Bigi wanted to explore even deeper down into it.

Page 67

#### The Second Pyramid

We come then to the second pyramid [of Chephren], which seems a little smaller than the first, and is a stone's throw away from it. There are no steps that can allow you to go up it on the outside. Furthermore, one sees that all the sides are of smooth marble, perfectly polished, and even until now one cannot find any entrance that gives access from the exterior. Consequently, given that it contains, as all the Egyptians truly believe, the tomb of a king, or, according to the opinion of many, of a queen, one could assume that one could enter into this pyramid from the large one [the Great Pyramid]. It is this that the Rev. Bigi immediately supposed and later told us that he had verified: one entered by the well and through the stone passages dividing at the bottom of the well, which we confirmed with certainty with the aid of a compass, namely that one passage went toward the nearby Sphinx, and one passage went toward this pyramid.

[This is a most extraordinary account. First of all, the Pyramid of Chephren is described as if it had most or all of its casing stones intact as late as 1584. But second, two square passages are said to have been encountered in the well shaft of the Great Pyramid, either at the point of what is called "the grotto" or at the point where the well shaft ends by opening into the Descending Passage, which passages joined one another and led off to the southeast and the southwest, and were blocked with stones and subsidences but were presumed to lead to the Sphinx and the Pyramid of Chephren. There is no knowledge of any such passage entrances today leading from the grotto, but then there are few if any people living who have ever been down the well shaft. This matter clearly requires some further study. Can it be that the entrances to two such passages have been obscured since the sixteenth century and forgotten? Several people explored the well shaft in the nineteenth century and early twentieth century, and they saw nothing of these passages. The grotto area is a small chamber containing much wet sand and gravel, and it is presumably possible that some of this fell across the entrances to some passages. So few people have ever scrutinized this grotto that we cannot be certain whether Alpin's account has any basis in fact. But if he had not encountered two passages, why should he claim that he had? It is at least worth checking out by a close inspection of the well shaft, but then access to the well shaft is now so restricted that even the Giza inspectors have not been down it and regard it as unsafe. Certainly, the well shaft is a claustrophobe's

worst nightmare, being exceedingly narrow and extremely deep and requiring one to be lowered on a rope. It is probably more likely that the two passages referred to are portions of the Descending Passage, the one leading to the right heading more or less in the direction of the Pyramid of Chephren (but as we now know, actually leading to the Subterranean Chamber and its strange small tunnel beyond that appears to come to a dead end). It is difficult to imagine, however, that anyone concluded the turning to the left could possibly be heading toward the Sphinx, as surely it must have been clear that it was merely the Descending Passage leading upward to the northern entrance of the pyramid. The use of a compass to determine direction is even more puzzling. Also puzzling is Bigi's wish to go down farther. What made him think he could do that if he had already reached the Descending Passage, where there is no indication that one can go any farther down? Or by "down" did he mean in the direction of what we now know to be the Subterranean Chamber? Since Bigi descended 70 paces, we must presume that by "pace" he meant the Byzantine pace rather than the larger and far earlier Roman pace, and as the Byzantine pace was equal to two and a half feet, this means that he had descended down the well shaft by 175 feet. However, the well shaft is 200 feet long at least. If Bigi really meant 70 feet, then that is the distance to the grotto. At the distance of 170 feet, the well shaft turns farther south before leading the remaining 30 feet down to the intersection with the Descending Passage. Could Bigi possibly be referring to this juncture, which is nearly 70 Byzantine paces down, at which an iron pin also occurs in the rock? Is it possible that at this juncture Bigi discovered an entrance to another passage that has not been noticed since that time because of a stone covering it? In Egyptian Dawn I publish a diagram showing the geometrical importance of the point of this juncture to the larger interior design plan of the pyramid, which suggests that it was not at all an arbitrary point, so a concealed passage entrance at that point is by no means inconceivable. I have never been able to gain access to the well shaft to carry out my own close inspections of the kind I would like.]

MICHAEL HEBERER VON BRETTEN (1585–1586)

Translated from volume 18 of the series Voyages en Égypte (1976)

Pages 67-68

Not far from the pyramids, one sees a figure called Andro-Sphinx, which the Egyptians made to honor two celestial [zodiacal] signs [Virgo and Leo] which each year brought them all the riches of the Nile. [This refers to the time of the annual inundation and its depositing of the silt.] They made it according to their custom, indicating their beliefs by signs, portraying a Virgin in front and a lion at the rear. From this, one can understand that their greatest riches and their well-being are visible when the sun is in the two signs, that is to say, in the months of July and August, those months [in] which the Nile rises to its maximum, distributing the water over the surrounding land. That is what they wanted to show by these signs and representations.

SEIGNEUR DE VILLAMONT (1590)

Translated from volume 3 of the series Voyages en Égypte (1971)

Page 198

[Heading of chapter 13] Full descriptions of the admirable pyramids of Egypt, of the Great Colossus or Idol [the Sphinx], and of the mummies that are in the sandy desert . . .

A little distance from the Great Pyramid, and almost adjoining the Nile, is a colossus or head of an idol of a most admirable size: the Campidogle of Rome is nothing compared to it in size. This head is raised on a column [he is referring to the Sphinx's neck; the paws and so forth were then covered in sand] made of a single piece of marble [i.e., limestone]; it is of a height of 92 feet, not including the column [neck] which supports it, and the thickness [grosseur] is 60 feet. Pliny gave it the credit of calling it the Sphinx, and said that its face extended 200 feet in width, and the length of its head is 423, which it is not; anyway, it is certainly a head of marvelous size and worthy of being given a marvelous number. It is said that in ancient times it was an oracle that gave responses to the Egyptians for the questions that they asked of it at sunrise.

CHRISTOPHE HARANT OF POLZIC AND BEZDRUZIC (1598) Translated from volume 5 of the series *Voyages en Égypte* (1972)

Page 191

# The Sphinx

Another thing worthy of admiration and which one finds in these parts is a head whose face resembles a human being and who rests on his neck, facing Cairo. The nose, the eyes, the mouth, the forehead, the cheeks, the ears, and the other elements of the head are cut by the hand of a master, and it is astonishing that all this has remained intact for such a long time. Pliny describes this head in these measurements: 144 feet [soulier, a "shoed foot," slightly larger than a foot (pied)] in height, the circumference from the level of the brow and whiskers at the front to the rear is 102 feet. All this is nothing but a single block of marble. It is not only the cutting, but also the transportation of such a stone, that command the admiration of all spectators.

Monsieur de Villamont in book 3 has written that the head is 92 feet high.

According to Pliny, this head had been the tomb of King Amasis, whose body was found in the interior. . . . Others say that this head was an image of the divinity of the Egyptians in the past and that Satan responded [as an oracle] to questions asked at sunrise or sunset. Blaise de Vinegère, in his *Les Images de Plattepeint de Philostrate* [*The Imagines of Philostratus*], says the same thing on that subject, and he adds that those who clamber to the top of the head are struck by misfortune; he cites the example of a Frenchman who, having done this, and led on by curiosity, clambered to the top of the head, and on his return journey to Cairo was thrown to the ground by his horse and killed.

# AQUILANTE ROCCHETTA (1599)

Translated from volume 11 of the series *Voyages en Égypte* (1974)

Page 58

(12) At the distance of an arquebus [an old-fashioned rifle] shot from the pyramids, one finds half of a marble statue that, I was told, was made as a certain idol where the pharaohs consulted the oracles; it is a marvelous thing. I did not measure the figure; it is 21 palms [palmes] in length. But I quickly left that place for fear of Arab thieves.

#### HENRY CASTELA (1600–1601 AD)

Translated from volume 11 of the series *Voyages en Égypte* (1974)

Page 181

#### **Prodigious Colossus**

I saw a half-figure of a statue, consisting of nothing but a head and shoulders, so excessively and prodigiously large that I could not imagine by whom it was constructed, there being so little means of transporting it in this sandy place. For its shoulders are of such size that according to my measurement they extend up to 80 spans [*brasses*], and from them to the summit of the head, I would say 20 spans. I leave it to those who have never seen the Colossus of Rhodes whether it could have had any greater bulk. This head is all damaged as a result of its antiquity, rather than by this nation's neglect.

#### **GEORGE SANDYS (1611)**

George Sandys, *A Relation of a Journey Begun An. Dom. 1610*, London, 1615, pages 102–103; reprinted later in Samuel Purchas, *Purchas His Pilgrimes* (London: 1625)

Part 2, page 896: "... the Journey of George Sandys in 1610 to the Middle East, including Egypt"

Page 910

#### The Colossus

Not far off from these the Colossus doth stand, unto the mouth consisting of the natural Rock as if for such a purpose advanced [provided] by Nature: the rest of huge flat stones laid thereon, wrought all together into the form of an Aethiopian woman: and adored heretofore by the countrey people as a rural Deity. Under this, they say, lyeth buried the body of Amasis. [Amasis was a pharaoh of the Twenty-sixth Dynasty, 570–526 BC.] Of shape, lesse monstrous than is Plinies report: who affirmeth, the head to be an hundred and two feet in compass, when the whole is but sixty feet high. The face is something disfigured by time, or by indignation of the Moors, detesting images. The aforesaid Author (together with others) do call it a Sphinx. The upper part of a Sphinx resembled a maide, and the lower a Lion; whereby the Egyptians defigured [represented] the increase of the River, (and consequently of their riches) then rising when the Sun is in Leo and Virgo. This but from the shoulders upward surmounteth the ground [i.e., all that could be seen above ground level at this time was from the shoulders upward], though Pliny give it a belly: which I know not how to reconcile unto the truth, unlesse the sand doe cover the remainder. By a Sphinx the Egyptians in their hieroglyphicks [re]presented an Harlot, having an amiable and alluring face, but withal the tyranny, and rapacity of a Lion: exercised over the poor heart-broken, and voluntarily perishing Lover.

The images of these they also erected before the entrances of their Temples; declaring that secrets of Philosophy, and sacred Mysterie, should be [en]folded in Aenigmaticall expressions, separated from the understanding of the prophane multitude.

# WILLIAM LITHGOW (1612)

A Most Delectable and True Discourse of an Admired And Painefull Peregrination from Scotland to the Most Famous Kingdomes in Europe, Asia, and Affricke, 1623 edition (London: 1614)

Betweene the biggest Pyramide, and Nylus [the River Nile], I saw a Colosse, or head of an Idoll, of a wonderful greatnesse; being all of one marble stone, erected on a round rocke: It is of height (not reckoning the Columne) above 815 [this is a typographical error] foote, and of circuite, 68. Pliny gave it the name Sphingo, and reported much more of the bignesse, largenesse, and length of it: but howsoever he erred in his description, yet I resolve my selfe, it is of so great a quantity, that the like thereof (being one intire [sic] piece) the world affordeth not [i.e., the like is not to be found elsewhere in the world], and may be reckoned amongst the rarest wonders: Some say, that anciently it was an Oracle, the which so soone as the Sunne arose, would give an answere to the Egyptians, of any thing by them demaunded [i.e., any question they asked].

[Note: The misprint giving 815 feet for the height also appears in the 1614 edition and the modern reprint of 1971. Probably the last digit is accurate, and the 81 was meant to be either a 3 or a 2, giving a height of either 25 feet or 35 feet. By "the column," Lithgow presumably refers to the base of the neck, just visible above the sand, which some people assumed was a column upon which the head rested.]

#### PIETRO DELLA VALLE (1614)

Les Fameux Voyages de Pietro della Valle, French translation of Viaggi di Pietro della Valle (Paris: 1664), 4 vols.

Vol. 1, page 228

... and there nearby I admired a huge head which they call the Sphinx, which is certainly a beautiful piece of stone in the shape that we represent. [Presumably, he refers to an engraving that is not in the French edition.] I cannot remember very well having seen if this rock is natural, from the area, or whether it has been carried there, but the latter is more likely because the country around there is very level and sandy, and the sand has increased in such a way that the Sphinx is buried there almost up to its shoulders. If it were carried there, the work involved would have been much more considerable than that of the obelisks, because it is so very big, although from its shape and situation, it would undoubtedly have been easier to convey such a thing than to construct the pyramids. At least one does not believe so much of them to be broken [as of the Sphinx]. I was not able to satisfy my curiosity further, because night surprised me, so much so that to get back to the little hamlet several miles away where I wanted to see some other pyramids [at Abusir], I was obliged to walk two or three hours in the dark.

VINCENT STOCHOVE AND GILLES FERMANEL (1631, JOINT ACCOUNT)
Translated from volume 15 of the series *Voyages en Égypte* (1975)

Pages 80–81

About four hundred steps from here we saw a great colossus called Sphinx; the ancient Egyptians called it the epitome of marvels. It was their principal idol, that which rendered their oracles by means of the devil. Its form is half woman and half bull. The head, with the front of the body, remains still outside the sand, but the rest of it is all covered up. The head, which has the face of a woman, is of two pikestaffs in height, and the rest of the body emerging is entirely cut from one single stone:

from it one can judge of its immense size.

#### ROBERT FAUVEL (1631)

Translated from volume 15 of the series *Voyages en Égypte* (1975)

Footnote on page 81 (MS De Rouen, page 439) [The reference to page 439 is to a page in the manuscript at Rouen. Page 81 is the page in the published book.]

It [the Sphinx] is all made from one piece of stone, hollow inside, having the head of a woman and the rest of the body like that of a cow. One only sees the head and some part of the body; the rest remains hidden under the sand.

#### HENRY BLUNT (1634 AD)

Translated from volume 13 of the series *Voyages en Égypte* (1974)

Page 44

#### The Sphinx of Giza

Within two bowshots from there is a rock, about 40 yards in perimeter and about 12 or 14 in height, cut in the form of the head of a man, perhaps that of Memnon, [which is] celebrated for the sound that it emitted at sunrise. [He refers here to the Colossus of Memnon near Thebes, which was noted for this sound, and is not suggesting that the Sphinx did this.] The Egyptians and the Jews who were with us [on this trip] told us that in olden times it had once rendered oracles, and also that it was hollow on top. They had seen several people go in there and come out again at the Pyramid. I immediately thought then of the story of the oracle, and I thought that all the other manifestations had the same cause, rather than the effect of the mist [he is referring to the morning mists, suggested as the cause of the sounds emitted by the Colossus of Memnon at Thebes, and assuming that one explanation for the oracles spoken by the Sphinx might be the same, but he then rejects this in favor of men hiding inside], although this would not be impossible, or even being of demoniacal origin, which would suppose too great a credulity.

[Later it was discovered that the original English text was cataloged in the British Library under the spelling "Blount" rather than "Blunt." Although the British Library does not have the original book *A Voyage into the Levant*, published in London in 1636, there is a modern facsimile reprint of it (Amsterdam and Norwood, New Jersey, 1977). The following is the original English text taken from page 47.]

. . . within two Bowes shoot hereof [from the Great Pyramid], is a Rocke of some fortie yards circumference, and twelve or fourteene high, cut into the forme of a mans head; perhaps Memnons, famous for its sounding at the Sunrise; the Egyptians, and Jewes with us, told us it gave Oracles of old, and also that it was hollow at the top; wherein they had seene some enter, and come out at the Pyramide: then I soone believed the Oracle, and esteeme all the rest to have beene such, rather than either by vapor, though not impossible, or Demoniacke, which require too much credulitie, for me.

GEORG CHRISTOFF VON NEITZSCHITZ (1636)

Translated from volume 13 of the series Voyages en Égypte (1974)

# On My Return Journey to Babylon [Cairo] and of an Oracle Encountered Enroute

After we had sufficiently examined the pyramids, we continued on our return journey to Babylon. But not far from here we came upon a rock of an extraordinary size, and formed by nature like the head of a man with huge ears, eyes, hair, and a long neck.

In this huge head would have lived, not many years before, an oracle, or divine diabolical spirit, who would reside apparently inside the pyramid described above, in a deep and dark hole through which one would have to pass with much care during the ascent and descent. Then it would return underground into that head, from where would be given counsel and instructions to the pagans on the subjects of which they had enquired. If the divine spirit had the same shape as presented by the head, it would not be astonishing that one would flee from it to a place assigned by it to knowledge and truth. Which is why one cannot ever be too amazed at the complete blindness of some poor people and should thank God for being free and illuminated by the knowledge of the sole true God, a knowledge which procures eternal salvation.

#### JOHN GREAVES (1637)

*Pyramidographia: or, A Description of the Pyramids in Aegypt* (London: 1646) Taken from A. and J. Churchill, *A Collection of Voyages and Travels, etc.* (London: 1732), 4 vols.

Vol. II, page 662

On the east-side of this room [the Queen's Chamber of the Great Pyramid], in the middle of it, there seems to have been a passage leading to some other place. Whether this way the priests went into the hollow of that huge sphinx, as Strabo and Pliny [book 36, chapter 12] term it, or androsphinx, as Herodotus calls such kinds, (being by Pliny's calculation 12 feet in compass about the head, in height 62, in length 143: And by my observation made of one intire [sic] stone) which stands not far distant without the Pyramid, southeast of it, or into any other private retirement, I cannot determine; and it may be too this served for no such purpose . . .

JEAN COPPIN (1638–1639 AND 1643–1646) Translated from volume 4 of the series *Voyages en Égypte* (1971)

Page 186

The Sphinx, or the head that I come to speak of, served as an oracle at Memphis before the coming of Christ, in that the demons spoke effectively from there where the priests went to place themselves in the statue by an underground vault, which it is said leads from the Great Pyramid down to the Colossus. Even though the Egyptians were blinded [misled] by the mistaken [oracular] responses that they received there, they were happy to be buried nearby, and that is the reason why one sees such a large number of sepulchres in that area. What is more surprising is that one is assured that it is bad luck to climb on top of the head, so that all those who out of curiosity climb up onto it soon suffer a great misfortune, even on the same day. I have always taken this sort of thing as a fable, but someone has confirmed to me a recent example of an Italian who soon after he came down from there was

killed by his horse. If this opinion be true, it is a great advantage for many people who have difficulty finding their way down from the top of this figure. I don't know if this proves that there is a bad spirit, but nobody can look at it without wanting to climb it.

# GABRIEL BRÉMOND (1643–1645)

Translated from volume 12 of the series *Voyages en Égypte* (1974)

Page 99

#### (12) Concerning the Idol of the Sphinx, or Head

This head, or Sphinx as one calls it, is a very beautiful piece of hard stone, well carved; and even though more than half of it is under the sand so that one cannot give a true opinion of the whole of it, it is well proportioned and a very fine work. From close up it looks like a great mass. One believes it to have been carried from a long way off, to be treasured all the more for the difficulty involved. It is hollow inside, and this was how [oracular] responses were uttered by a man hiding within. Only the head, neck, and a little bit of shoulders appear above the sand. The figure represents a young adolescent or a woman.

#### BALTHAZAR DE MONCONYS (1646–1647)

Translated from volume 8 of the series *Voyages en Égypte* (1973)

Page 63

. . . after that [seeing the second pyramid] we came to the foot of the Idol [the Sphinx], which is 26 feet high and has hair to its chin, which is a part extending 15 feet from the head; from there we went on to the mummies [at Saqqara] . . .

# JEAN DE THÉVENOT (1655)

*The Travels of Monsieur de Thevenot into the Levant* (London: 1687), 3 vols. in one. (Translation of *Relation d'un Voyage Fait au Levant*, 3 vols., Paris, 1664–84.)

Vol. I, pages 134–35

Before each of the three Pyramides, the marks [should be translated "remains"] of certain square Buildings are still to be seen, which seem to have been so many Temples; and there is a hole at the end of the pretended Temple of the second Pyramide [which is now called the Valley Temple], by which (some think) there was a way down within the Temple to go to [should be translated "by which one went down from inside the Temple to go into"] the Idol [the Sphinx], which is a few steps distant from that hole.\* The Arabs call this Idol Abou el haoun, that is to say, Father of the Pillar, which Pliny calls Sphynx, saying that the People of the Countrey believe King Amasis was buried in it: I am sure they believe no such thing at present, nor so much as know the name of Amasis; and indeed, it is an erroneous belief. Others say, that a King of Aegypt caused this Figure to be made in memory of a certain Rhodope, a Corinthian Woman, with whom he was much in love. It is said, that this Sphynx, so soon as the Sun was up, gave responses to anything it was consulted about; and hence it is that all who go into the Pyramides, fail not to say, that a Priest conveyed himself into that Idol, by

the Pit or Well [the so-called well shaft] in the Pyramide which we just now described. But to shew how groundless an Opinion that is, we must know how the Idol is made: It is the Bust of a Body, at some steps distance from the open Pyramide [the Great Pyramid was the only one open at that time], cut out of the natural Rock, from which it hath never been separated, though it seem to be of five Stones pieced together one upon another; but, having very attentively considered it, we observed, that that which at first seemed to be seams or joynings [joinings] of the Stones, are only veins in the Rock: this Bust represents the face and breast of a Woman, but it is prodigiously high, being twenty six foot in height, fifteen foot from the ear to the chin, and yet all the proportions [are] exactly observed: Now what probability is there to believe, that every day a man would take the paines, and venture the breaking of his neck, by descending into that Pit, that being at the bottom, he might only have the labour of coming up again, for there is no passage there, as they who have gone down have observed; a passage must have been cut in the Rock then, which would have cost a great deal of Money, and been known of [by] every Body. It were more probable [would be more likely] to think that they entered it by the Hole, which (as I said) is in the pretended Temple of the second Pyramide, or rather by another [hole], which is at the side of that Idol and very near it [i.e., near the head, most of the body being covered by sand]. These two Holes are very narrow, and almost choaked [choked] up with Sand, wherefore we entred not into them, not knowing besides, but that we might meet with Vipers, or other Venemous Beasts in them. But though there had been a way through the Rocks into that Idol, how could the Voice of that feigned Oracle have come out, since there is no hole neither at the Mouth, Nose, Eyes, nor Ears of it? $^{*2}$  It may be said, perhaps, that the Voice was uttered by the Crown of the Head, where there is a Hole, into which we endeavoured to have cast some Hooks fastened to Ropes, that I had brought purposely with me, that we might get up, but we cold not compass [achieve] that, because of the height of it; only when we threw up Stones, they rested there. And a Venetian assured me, that he and some others, having got up by means of little Hooks and a Pole, which they brought with them; they found a Hole in the Crown of the Head of it, and having entered therein perceived that it drew narrower and narrower proportionably, as it approached the Breast where it ended. The voice of him that entred then, by the abovementioned Holes, did not come out that way, and therefore it must be concluded, that if any entred it, it must have been by a Ladder in the Nighttime, and that he put himself into the hole that is in the Head, out of which the Voice came.

# **EDWARD MELTON (1661)**

Eduward Meltons Eengelsch Edelmans, zeldzaame en Gedenkwardige Zee- en Land-Reizen; door Egypten . . . (Amsterdam: 1681 and 1702)

# Page 51

[Note: This work and author are in all probability spurious. The account of the Sphinx is plagiarized from those of Johann Wansleben and Jean de Thevenot. It is doubtful if any Edward Melton ever existed; although he is described as "an English nobleman," no Edward Melton ever published a word in English, and the name is probably invented. I consulted a seventeenth-century manuscript pedigree of the Melton family in the British Library (MS Egerton 3402, f. 119 verso), and there is no Edward mentioned anywhere in it.]

# **Description of the Sphinx**

We decided to see the Sphinx, which is located to the east of the Pyramids. It has the head and half of the breast of a woman and is of an impressive size. It is 26 feet tall and fifteen feet from chin to ear.

Pliny tells us that the Sphinx is the location of the grave of King Amasis. I like to believe it is a grave, but I am not sure whether it is the grave of King Amasis. It is hard to say, since the original texts are lost.

Some say that the Sphinx is made to look like a certain courtesan named Rhodope. She was considered the prettiest woman of Thrace in her time and admired by the king who is buried in this grave.

We can speak of a grave for certain since the Sphinx is located at a place that used to be a burial ground. Second, it stands close to the Pyramids and the caves, which are nothing but grave-cities. Besides this, it's obvious from the shape that the Sphinx contains a basement as wide as the height of the Sphinx. It also has an entrance. This basement was without doubt used to bury the bodies of dead men.

By the use of a rope ladder that we brought, we climbed all the way up to the head of the Sphinx to see if it was hollow. It was, but it was filled with sand so we could not tell the size of the space inside. We also found that the neck was badly damaged. It looked like the seams couldn't carry the head much longer.

When one looks at this miracle from a little distance, it seems to be made out of five stones. But when you come closer, you find that the lines you first thought were seams turn out to be the veins in the stone.

# PÈRE ANTONIUS GONZALES (1665-1666)

Translated from volume 19 of the series *Voyages en Égypte* (2 parts, 1977)

Part 1, pages 144–46 Chapter 14

# Description of the Sphinx Idol, of Mummies and of Embalmed Cadavers

Tacitus [*Annals*, 50, 2, chapter 61] wrote that Germanicus saw near the pyramids a stone statue of Memnon, which emitted sound when the rays of the sun touched it or illuminated it [at dawn; this is a confusion, for the famous statue in question, known as the Colossus of Memnon, is near Thebes, not at Giza]. But I have the impression that this statue is that of an old idol, which is one called Sphinx, and which was situated not far from the pyramids, about a quarter of an hour. There today arises a large head or monster, astonishing in its shape and grandeur. On the subject of this monster, Pliny wrote the following (book 36, chapter 12): "In front of the pyramids is found a Sphinx, very admirable indeed, apparently a sylvan god of the locals. It is thought that King Amasis is interred there. The common opinion holds that he was placed there. It is polished, cut from natural rock. The head of this monster has a circumference of 102 feet and a length of 143 feet." I do not wish to judge the height and size of this head, because we had no instruments for measuring them at the time. I only know that the head of this monster is enormous, and that it is called even up until today the idol Sphinx.

Formerly it was the most important idol of the Egyptians, which foretold to them many things that the Devil knew. They took its counsel, and she revealed to them numerous things that took place.

The upper part resembles a man, the lower part is like a bull, one is told by the people of the vicinity. The upper part remains above the sand; the lower part, on the contrary, is entirely covered. If it be true that the rest, or the lower part, is proportionate in size to the upper part, one must consider

that it is one of the Seven Wonders of the World, for it seems to be cut from one piece of stone. Some people ask themselves if this stone colossus was cut from a natural rock in situ, or if it had been carried from elsewhere. Plenty of people have wanted to examine it by excavation but they could not because of the sand. Others thought that this monster consisted of nothing more than half a body, for under the neck there is an opening of a stone tunnel which passes across the mountain of sand up to the pyramids, where it ends. Radzivil [Prince Mikolaj Krzystof Radziwill Sierotka (1549–1616)] (1583 AD) believes equally in oracles coming out of the mouth of the Sphinx. [Radziwill's account of his journey to the Middle East in 1582–1584 was originally published in Polish as *Peregrynacia* . . . , unknown date, and then translated first into Latin by Thomas Traterus as Hierosolymitana peregrinatio . . . , Brunsberg, Germany, 1601, and later into German by Lorenz von Borkau as Jungst Geschehene Hierosolymitanische Reyse, and published in S. Feyerabend's anthology Reyssbuch dess Heyligen Lands, 1609. Unfortunately, this information came to light just as this book was going to press, too late for me to consult the German version in the British Library and translate Radziwill's account of the Sphinx into English for inclusion in this book.] For this reason, there are some people who suppose that the priests of this idol went by way of this tunnel into the head. Fuerer (1565 AD) thinks that there is a special channel. [This reference is to Christopher Fuerer von Haimendorff, Itinerarium Aegypti . . . (Nuremberg: 1620), also published in German in 1646; 1565 is the date of his journey to Egypt, not the date of publication.] As I said in the preceding chapter, inside the Great Pyramid is a well that seems to open into a tunnel leading toward this head.

But for myself, I believe furthermore that the Devil spoke and replied through this head to fool the poor idolators. For the people told us that if someone had lost a camel, an ox, or a donkey, he would go and burn a little incense in front of this idol, he asked counsel, and after its response he found these missing animals. The Devil knows a lot more than man. *A fortiori*, I have not discovered any openings in the mouth of this head, or any other openings by which the priests could have spoken.

About a hundred paces from there are numerous brick and mortar ruins and extraordinary little hollow chambers in the rock, with some figures and writing in Arabic or Hebrew characters. Some people think that the priests of the idol Sphinx once lived there. Others believe that they were hollowed out by the kings of Egypt and other princes related to them, during the construction of the pyramids, as shelters protected from the sun where they could watch the workmen.

#### Page 142

Near this chamber [the King's Chamber] another passage opens in the direction eastward, which ends in a second small chamber [this refers to the Queen's Chamber and the passage running southward to it from the bottom of the Grand Gallery] and has a well quite near [the entrance to the well shaft in front of the passage to the Queen's Chamber], wide and deep, with a kind of stairs. One of our soldiers went down there and found a new passage or way, which it seemed to him went down towards the idol Sphinx of which we will speak in the next chapter. As no one had the desire to follow this soldier, and also because our time was running out, he left the well and we departed from the Pyramid together. On leaving, I noticed some passages to the left, but each time one goes there, one always looks at the main things and still has to hurry away.

**CORNEILLE LEBRUN (1674)** 

Cornelis de Bruyn, Voyage au Levant (Paris: 1725)

Some distance from the largest pyramid on the east side, one sees the Sphinx, famous with the ancients. It is a statue that has been cut from the same rock, representing a woman's head with half of the chest; but just now it is buried up to the neck in sand. On the right hand, the sand is higher than elsewhere to quite a large extent; in a manner that could easily lead one to believe that under this elevation is hidden the rest of the body, which resembles a lion, with its face turned to the right. It is an extraordinarily large mass, but where the proportions can still be seen, even the head alone is 26 feet high, and from the ear to the chin is 14, according to the measurements taken by Monsieur Thévenot. From a distance it seems to be five stones joined together; but when you get closer, you see that what you had taken to be joints of stones are in fact veins in the rock. Pliny states that this colossus was the tomb of the King Amasis, which is not so unbelievable, since it is in a place which was formerly, as we have said, a type of cemetery, and close to the pyramids and the caves that were for that same purpose; but to know whether it was specifically that of King Amasis, is something I cannot assure you of because there is no way it can be proved for certain, all memoirs of that antiquity being lost.

Other people wanted to believe that an Egyptian king had this sphinx built in memory of a certain Rhodope of Corinth with whom he was passionately enamored. Writers have written much about this sphinx. They say, among other things, that she rendered oracles, which was undoubtedly the result of trickery by the priests, who practiced it in nearby subterranean passages. Some people believe that the well that is in the great pyramid could have been used for this. Although one no longer finds any passageway today, perhaps this is because it has been blocked by the caving-in of the earth. Thus one can offer no assurance on this matter. What is certain is that there is no opening there, neither from the mouth, nose, eyes, nor ears; and if the priests had placed here some method of deceit, it would have to have been by means of a hole, with someone climbing up a ladder to the top of the head and descending into the chest, where it [the hole] would end. The Consul, with most of our company, rested in the shade of this great mass while I was occupied with drawing the pyramids, which are nearby. One could easily, upon inspection of the figure, judge the grandeur of this monstrous statue by the proportion one observes between it and people standing roundabout. As for the particular details of the Sphinx in general, I am happy to refer to what Dr. O. [Olfert] Dapper has written of it, and which he had himself borrowed from others. [Much of what is said above is quoted or paraphrased from Thévenot. As for Dapper's book, it appeared under three different titles, twice in 1681 and once in 1688, all published at Nuremberg, but I have been unable to consult it so Dapper's account is missing here.]

He says that when the Egyptians deal with nature, they represent the sphinx in two ways; namely, in the figure of a crouching lion on its belly, or in the form of a type of monster that has the body of a lion and the face of a girl. By the first figure they represent Momphta [presumably he refers to the deity called Hapi], who was one of the Egyptian divinities who lived in all the waters, and who particularly maintained and preserved the causes of the inundation of the Nile; and by the second they represent the same increase of this river. . . . [Much of the omitted text deals with mythology and the overflowing of the Nile, and so forth] . . . They [the Greek authors of fables and mythological tales] had said according to the evidence of Hyginus and some others that the [Greek] Sphinx was a monster born from Typhon and Echidna, that it had the head and the face of a girl, the wings of a bird, and the body of a dog. Or, as Clearchus said of it, the head and hands of a girl, the body of a dog, the tail of a

dragon, the claws of a lion, the wings of an eagle. It was, they say, in Boetia on the Mountain Sphincius near Thebes, from where it had the custom to throw passersby from the cliff and propose to them a riddle to which they would have to give the answer. . . .

#### ELLIS VERYARD (1678)

Translated from volume 23 of the series *Voyages en Égypte* (1981)

Pages 47–48

# The Sphinx

Approximately a half mile from the pyramids, we saw an ancient colossus representing the Sphinx, with a face of a woman and a body of an animal. This statue was apparently held in such great veneration by the Egyptians that they gave it first place among their gods. They received from it all their oracles, which the devil pronounced from the mouth of this artificial monster. The body is buried in sand and only the breast and the head are above the ground. Thus one can judge the enormous size of the whole thing from the face, which is 24 feet long. Pliny says that it was the tomb of the King Amasis, but I tend to believe that it was an ornament placed on his sepulchre, for in the rear one finds a subterranean vault hollowed out of the hard rock, which in all likelihood was the tomb.

ELLIS VERYARD (1678; THE ORIGINAL ENGLISH TEXT)

An Account of Divers Choice Remarks . . . Taken In a Journey through . . . Egypt . . . etc. (London: 1701)

Page 298

About half a Mile from the Pyramids we saw an ancient Colossus representing the Sphinx, with a Woman's face, and the Body of a Beast. This Statue was in so great Veneration amongst the Egyptians heretofore, that they gave it the first place amongst their Gods, and received all their Oracles from it, which the Devil utter'd thro' the Mouth of this artificial Monster. The Body is buried in the Sand, and only the Head and Breast remain above Ground; so that we may judge of the vast bulk of the whole by the Face, which is twenty four foot long. Pliny says it was the Tomb of King Amasis; but I am apt to think it was an Ornament placed on his Sepulchre; for behind it we found a Subterranean Vault cut out in the firm Rock, which in all likelihood was the Tomb.

Description de l'Égypte (Paris: 1735)

Pages 221-23

# Concerning the Sphinx

Opposite the second pyramid, and exactly to the east is this famous sphinx, of which so many accounts have spoken. It is at least 300 paces away from the pyramid, and from there one can count 200 paces from it up to the spot where the Nile laps at the pyramid plateau. It is a woman's head grafted onto the body of a lion crouching on its belly. This head would probably still be entire if the Mohamedans had not disfigured it. Someone has broken off the nose. The body has been damaged by the passing of

years; one sees today only the shape of it, the lower part being buried under the sand. It is a stupendous head, more than 35 paces in circumference on a body that is more than 30 paces long. As several authors have spoken of this colossus, I will content myself with adding to what they have said about it, that although the head has a hole which has been hollowed from above, there is nevertheless, from this void, no connection with the mouth, nor is there any other place on the inside of the figure through which one would have been able to speak, as some people have claimed. I will add that this hole has very little depth and that far from being a communication to the interior of the first pyramid, as some people have falsely imagined, it would be much more natural to believe, if it were true that this artificial tunnel actually exists, that it would lead to the inside of the second pyramid, to which it corresponds so perfectly in its position.

This idol could have had several intended purposes. Perhaps it was not maintained for any specific use, but rather to be admired for its astonishing size. It could have been made from a mountain of stones that were smoothed as proof of those who had removed it, in the same way that today one leaves signs on ground that one has made level. One could even have used it as an auspicious arrangement of the locality, by cutting a figure in the rock which surprises succeeding generations.

Some people say that it was a talisman, others that it was an idol that was adored. What is most likely is that this union of the head of a girl with a body of a lion, so common and ordinary and which we see represented so frequently in Egypt, was a symbol of what happened in that country under the signs of Virgo and Leo. It is in effect in that season, when the sun traverses them, that the Nile overflows and makes Egypt fertile and habitable with its inundation. The kings of Egypt did not believe they could bear better witness to the sun than in their recognition of it as the author of their happiness by consecrating this mysterious figure to him.

Several people have claimed that the sphinx of the pyramids, or at least the head of that prodigious colossus, was composed of several stones placed and well cemented one on the other. What made it possible to have this idea was that in three or four places around this mass one notices, in effect, veins that circle around the head in an almost horizontal way and that these veins seem to contain a kind of mastic of a different color than the stone. For my part, having looked closely at these veins, I am of the persuasion that they are natural to the stone. When one cannot be convinced of it by investigation, when in several places there is no slanting [he is referring to the fact that the rock layers are all tilted and slant slightly at the Sphinx], it would be enough, to ease one's doubt, to take a look at some of the small pyramids not far from this figure that are placed on the level stretch of the same rock. There, one discovers similar veins, which prove manifestly that those observed in the head of the sphinx, like these, are made of nothing more than little bits of stone that are a characteristic of this terrain. I believe that this figure was formerly covered by a temple. The proof I have of this is that the head of the figure is still, today, complete in all parts, where it has not had violence done to it by the hand of man rather than under the chisel. The reddish paint with which it was covered is still there. One notices elsewhere around the colossus a kind of circuit, where the sand under which it is buried stays higher than the rest of it; and I have no doubt that it hides the foundations and the debris of this edifice, which served as the temple to the idol.

On going again from the sphinx back toward the second of the great pyramids, to the front of which, and precisely in the middle, the colossus was placed on the east side, one discovers about 4 paces from the pyramid the remains of another temple, which is almost opposite it. [He is referring to the Funerary Temple of Chephren.] I was surprised that no other traveler that I know of has spoken of this monument, of which for several thousands of years, the intended purpose would not still be in doubt.

One finds a similar temple [the Funerary Temple of Mycerinus] opposite the third pyramid and at the same distance from it.

This one is more complete than the first. [These are the funerary temples of Chephren and Mycerinus, which stood at the feet of these two pyramids.]

#### GIOVANNI FRANCESCO GEMELLI-CARERI (1693)

A Voyage Round the World

Translated from the Italian; the voyage commenced June 1693 Taken from A. and J. Churchill, eds., *A Collection of Voyages and Travels* (London: 1732), 4 vols., folio

Vol. IV, page 23 [Referring to the "well shaft" in the Great Pyramid]

Between the two ways already mentioned, on the right hand, is a wall, which appears on the ground perpendicularly from the Horizon, making the figure of the Hebrew Lamed [a letter], in which down seventy-seven foot, there is a square window, or inlet to a small cavern cut out of the soft stone that runs westward; the pyramid being built on the hard rock. Down fifteen foot in this cavern, there is an oblique way, cut in the same stone, two foot and four inches in breadth, and two foot and an half in height, descending 123 foot, where it is stopped up with sand and stones. [The sand and stones were finally cleared by Captain Caviglia in 1817.] Those Barbarians say, there was a passage there underground, to the empty head of an idol [the Sphinx], that stood not far from the pyramid. As much of this idol as remains, which is from the shoulders upwards, is twenty six foot in length to the top of the head, and from the ear to the chin fifteen. All this that has been said, will appear the more plainly, by the following cut. [Cut is an old-fashioned term for an engraving; he refers to an accompanying engraving of the Great Pyramid in section, which, however, shows the internal passages incorrectly drawn.]

# **ROBERT HUNTINGTON (1695)**

Apparently never published in English. Translated from volume 23 of the series *Voyages en Égypte* (1981)

Page 167

I would consider it an impiety to forget the Sphinx or statue with a human head. Its bulk is enormous; it is 100 feet in circumference at the level of the shoulders.

It is cut from a single stone and faces toward the east.

Page 193

And of this kind of porphyry is the celebrated Sphinx (an enormous head and shoulders, the whole being 110 feet in circumference), still standing near the north pyramid [the Great Pyramid].

[Obviously, the Sphinx is made of limestone, not of porphyry, so Huntington is in error.]

#### ANTOINE MORISON (1697)

Translated from volume 17 in the series *Voyages en Égypte* (1976).

Page xxiv (editor's introduction)

After the visit to the other pyramids, his excursion ended at the Great Sphinx. He was full of admiration. In supplying the exact dimensions of the monument; he declared that he "pitied Pliny for his exaggerations" (page 166). Meanwhile, without hesitation he claimed that the head of the Sphinx was hollow. This proves that he had only seen the fabulous androcephalic monument either superficially or from afar.

[The editors of Morison appear to be unaware that travelers for centuries had been told that the head of the Sphinx was hollow, and Morison's statement certainly does not prove that he had seen the Sphinx only "superficially or from afar." All it proves is that the same tradition was being repeated to him by the local guides as had been told to visitors for centuries.]

Pages 175-76

About two hundred steps from the Great Pyramid on the east side, one sees the head of a sphinx, whose body is buried in the sand. It seems that the neck of this figure may be 15 feet high, and the head, which is still complete, is of such an extraordinary size that it provided enough shade for eleven people—which we were—to protect us from the extreme heat of the sand, from which we were suffering. As its figure is doubtless proportionate, it would have to be more than 100 feet long, and consequently its size is prodigious. [The length of the excavated Sphinx from the paws to the tail is now known to be 57 meters (187 feet), the height 20 meters (66 feet).] Pliny [book 36, chapter 17] speaks of it with such exaggeration that I feel sorry for him, and I would doubt his accuracy in other things, judging by his credulity in this matter. The head of this sphinx is hollow, that is, according to the priests of these nearby ruins and temples of whom I come to speak. Under cover of night, they would hide in this head and stay there to speak on certain appointed days to the people who had assembled there and who listened to the discourses of these impostors as if they were oracles being pronounced by that idol. What I most admired about this monstrous divinity was the vivacity of its coloring and above all the vermilion of its cheeks, which seemed to have been applied only two years ago, even though it must have been there for more than two thousand years.

[He then mentions collecting petrified wood from the desert, and a Lake Karoun at Giza, which is not the same as Lake Karoun in the Fayyum.]

JOANNES AEGIDIUS VAN EGMOND VAN DER NIJENBURG AND JAN HEYMAN (1709)

*Travels through Part of Europe, Asia Minor . . . Egypt . . .* Translated from the Low Dutch (London: 1759), 2 vols.

Vol. II, page 90

After this survey of the first and largest pyramid, we visited the head of the sphinx, and the second and third pyramids. With regard to the former, it is the bust of a woman, with the nose a little mutilated, and is said to have been formed out of one single rock. But I could find no reason for

calling it a sphinx, nothing but the head and neck being seen, though the height is full thirty-feet. And it is a question, whether there ever was anything more of this image than what is at present visible; though Pliny, and others, mention a body, and give it a really amazing magnitude, making the circumference of it to be one hundred and two feet. Some later writers have also mentioned a subterraneous passage from the largest Pyramid to this head, which they say is hollow; and that the Pagan priests used to deliver their oracles here. But all this is mere conjecture. . . . About a mile from hence stands the second pyramid. This structure, from the pieces which, in several places, still cover it, appears to have been covered with marble; but hitherto the entrance of it has not been discovered. It is, except on the south-side, well preserved, having neither chasms nor fissures; and from its surface being every where smooth and even, there is no possibility of ascending it.

[This astonishing description of the Chephren Pyramid in 1709 suggests that the limestone casing stones had not yet been stripped from it, and that the story believed today that they were all taken away in the thirteenth century to rebuild Cairo after an earthquake is false. The pyramid seems to have been stripped of its casing stones as recently as the first half of the eighteenth century, if we are to believe this account by Egmond. The entirety of the casing stones is also represented as being intact in a woodcut published in 1579, from a drawing done in 1565, in the book by Johann Helffrich (see above for a translation of the section of his text dealing with the Sphinx). This woodcut shows the casing stones of the Pyramid of Mycerinus intact as well, but the Great Pyramid is shown as entirely stripped of them, and with the pyramidion missing at the apex. It seems therefore that it was solely the casing stones of the Great Pyramid that were stripped away in the thirteenth century, and no others.]

#### THOMAS SHAW (1721)

Travels, or Observations Relating to Several Parts of Barbary and the Levant (Oxford: 1738)

Pages 368-69

... the catacombs of Sakara [Saqqara], the Sphinx, and the Chambers, that are cut out of the natural rock, on the east and west side of these pyramids, do all of them discover the specific mark and characteristics of the pyramidal stones, and, as far as I could perceive, were not at all to be distinguished from them. The pyramidal stones, therefore, were, in all probability, taken from this neighbourhood; nay perhaps they were those very stones, that had been dug away, to give the Sphinx, and the chambers I have mentioned, their proper views and elevations.

Pages 374–75

# Of the Sphinx

Besides what has been already said of the Sphinx, we are to observe, that in July 1721, the sands were so far raised and accumulated about it, that we could only discover the back of it; upon which, over the rump, there was a square hole, about four feet long, and two broad, so closely filled with sand, that we could not lay it open enough to observe, whether it had been originally contrived for the admission of fresh air; or, like the well in the great pyramid, was intended for a stair-case. Upon the head of it there is another hole, of a round figure; which, I was told, for we could not get up to it, is five or six feet deep, and wide enough to receive a well-grown person. The stone, which this part of the head consists of, seems, from the colour, to be adventitious, and different from the rest of the

figure, which is all of the same stone, and hewn out of the natural rock. [This is a very sharp observation, for we now know that the head was carved from a stratum of stronger limestone than the body and is indeed harder and "different," quite apart from the fact that also it was cut down and recarved by a later pharaoh in his own image.] It must be left to future travellers to find out, whether these holes served only to transmit a succession of fresh air into the body of the sphinx, or whether they might not have had likewise a communication with the great pyramid, either by the well, or by the cavity or nich [niche] in the wall of the lower chamber [the Subterranean Chamber], that lies upon a level with it. Nay, it may some time appear, that there are chambers also in the two other pyramids [we now know this to be true]; and not only so, but that the eminence likewise, upon which they are both erected, is cut out into cryptae [crypts], narrow passages, and labyrinths, which may, all of them, communicate with the chambers of the priests, the artful contrivers of these adyta; where their initiatory, as well as other mysterious rites and ceremonies, were to be carried on with the greater awe and solemnity.

#### CHARLES THOMPSON (1733)

Travels through Turkey in Asia, the Holy Land, Egypt, and Other Parts of the World (London: 1754), 2 vols.

Vol. II, pages 143-44

Before I leave this Place [Giza], I must take some Notice of a Colossus, at least the Head of one, which stands about a Quarter of a Mile to the East of the second Pyramid. It is usually call'd a Sphinx, which is a fabulous Monster, having the Head and Breasts of a Woman, the Wings of a Bird, the Claws of a Lion, and the Body like a Dog. This figure, among the Egyptians, was a symbolical Representation of the rising of the Nile in the months of July and August, when the Sun passes through the Signs Leo and Virgo. They likewise made use of it in their Hieroglyphicks to represent a Harlot, intimating the Danger of being captivated by the Charms of a faithless Woman, whom the fond Lover in the End finds as cruel and rapacious as a Lion. Of this Sphinx however, near the Pyramids, there is little to be discern'd but from the Shoulders upwards, being a monstrous Bust of a Woman, all cut out of the solid Rock, and never separated from it; except the upper Part of the Head, which seems to be adventitious [added on]. It is almost thirty Feet high, fifteen feet from the Ear to the Chin, and above thirty feet wide at the lower Part of the Neck or Beginning of the Breast. The sand is so accumulated about it, that one can but just discover the Top of the Back, in which there is a Hole about five Feet long, seventy-five [feet] from the hinder Part of the Neck, and thirty from the Tail. We could not get up to the Top of the Head, but those who have done it report, that there is a round Hole, by which a fullgrown Person may descend into it, from whence it is supposed the artful Priests deliver'd their Oracles. Pliny makes mention of this Sphinx, and tells us that it was thought to be the Sepulchre of King Amasis. The Rock is dug away all round the Sphinx to a considerable Distance, and the Stone was undoubtedly employ'd in building the Pyramids, with which some Moderns have supposed it has a subterraneous Communication.

# RICHARD POCOCKE (1743)

The Rt. Rev. Richard Pococke, successively bishop of Ossory and of Meath; *A Description of the East and Some Other Countries* (London: 1743–1745), 2 vols, folio

[Note: The manuscript of this material is not among the twenty-one volumes of travel diaries of Pococke, which are preserved in the British Library (Add. MSS. 22,978–22,998), probably because the original manuscript went to the publisher and was not returned to Pococke afterward. However, some further remarks about the Sphinx from one of Pococke's letters to his mother are given below.]

From 457.f.8, an edition of 3 vols. (vol. II bound in two parts) Vol. I, page 46

Directly in front of the second pyramid, about a quarter of a mile to the east of it, is the famous sphinx H [a reference to his engraving, figure XVI, where the Sphinx is marked H on a plan of the Giza Plateau] about half a quarter of a mile from the water when the Nile overflows, being on much lower ground than the pyramids. Here seems to have been the grand way up to these magnificent structures. . . . The rock seems to have been dug away all round the sphinx for a great way, and the stone was doubtless employ'd in building the pyramids, the sphinx being cut out of the solid rock; for what has been taken by some to be the joining of the stone, is only veins in the rock. This extraordinary monument is said to have been the sepulchre of Amasis, tho' I think it is mention'd by none of the antient authors, except Pliny [book 36, chapter 12; Pococke's footnote here states: "My account makes the sphinx one hundred and thirty feet long, that is about seventeen feet more than Pliny. He says it was sixty-three feet high, probably taking in a plinth that might be cut out under it; so that about thirtysix feet must be buried in the sand."] I found by the quadrant that it is about twenty-seven feet high, the neck and head only being above ground; the lower part of the neck, or the beginning of the breast, is thirty-three feet wide, and it is twenty feet from the fore part of the neck to the back, and thence to the hole in the back it is seventy-five feet, the hole being five feet long, from which to the tail, if I mistake not, it is thirty feet; which something exceeds Pliny's account, who says that it is a hundred and thirteen feet long. The sand is risen up in such a manner that the top of the back only is to be seen; some persons have lately got to the top of the head, where they found a hole, which probably served for the arts of the priests in uttering oracles; as that in the back might be to descend to the apartments beneath.

Letter 26 to his mother, dated March 3, 1738 or 1739, from British Library Add. MS. 22,998, f. 67

I went to the Sphynx the head much worn by time, especially the neck, one just sees the top of the back & either a tail or a thigh in a sitting posture;—the whole by the nicest examination I could make seems to be cut out of the rock;—went into some catacombs & round the second Pyramid. We dined together & returned . . .

# **CLAUDE LOUIS FOURMONT (1755)**

Description Historique et Geographique des Plaines d'Heliopolis et de Memphis (Paris: 1755)

Pages 255-56

To the east, and more than 300 paces from this pyramid, we visited the Sphinx, whose name among the local people is Abou-Ehoul, which is to say, Powerful Father. In the front it is a head of a woman, resting upon the body of a lion lying on its belly. Someone has broken off its nose; the body has been damaged by the passing of years. Today, one sees only the shape of it, of which the lower part is buried under the sand. Its head is more than 35 feet high. This Sphinx was a symbol of what happened in Egypt under the signs of Leo and Virgo when the Nile overflowed, rendering Egypt fertile and

habitable by this inundation.

#### FRIDERIK NORDEN (1757)

*Travels in Egypt and Nubia*, by "Frederick Lewis Norden," i.e., Friderik Ludvig Norden, Captain of the Danish Navy, trans. from the [Danish] original and enlarged by Dr. Peter Templeman (London: 1757), 2 vols.

Vol. 1, page 76

About three hundred paces to the east of the second pyramid, you see the head of the great and famous Sphinx, which I have taken care to delineate. [See plates XLV, XLVI, and XLVII.]

In *Observations on Egypt*, page 46, Doctor [Richard] Pococke observes: "That this Sphynx is cut out of a solid rock. This extraordinary monument is said to have been the sepulchre of AMASIS, though I think it is mentioned by none of the ancient authors, except PLINY, lib. xxxvi, cap. 12. I found by the quadrant that it is about twenty seven feet high, the neck and head only being above ground; the lower part of the neck, or the beginning of the breast is thirty feet wide, and it is twenty feet from the forepart of the neck to the back; and thence to the hole in the back, it is seventy five feet, the hole being five feet long; from which to the tail, if I mistake it not, it is thirty feet; which something exceeds PLINY's account, who says that it is one hundred and thirteen feet long. The sand is risen up in such a manner, that the top of the back only is seen; some persons have lately got to the top of the head, where they found a hole, which probably served for the arts of the priests in uttering oracles; as that in the back might be to descend to the apartments beneath."

Monsieur [Benoit de] Maillet is of opinion "That the union of the head of a virgin, with the body of a lion, is a symbol of what happens in this country, when the sun is in the signs of Leo and Virgo, and the Nile overflows." The wings were probably added to the Sphynx, as emblematical of the *fuga tempo-rum* [time flying].

Vol. 1, page 73 [Important evidence about water reaching the Sphinx in the eighteenth century]

But when the waters have swollen to their highest pitch, you may go by water from Old Cairo quite to the rock, on which the pyramids are built.

Vol. 1, page 80

After having well considered this first pyramid, you take leave of it, and approach the second, which is very soon dispatched, because it has not been opened. You see there the ruins of a temple, that it has on the east side; and, descending insensibly, you arrive at the Sphinx, whose enormous size attracts your admiration, and at the same time you conceive a sort of indignation at those, who have had the brutality to disfigure strangely its nose.

Vol. 1, page 92 in his section (pages 84–95) "Remarks upon the Pyramidographia of Mr. John Greaves," ref. page 119 of Greaves, edited by Birch

[quote from Greaves]: "On the east side of this room [the Queen's Chamber], in the middle of it [the east wall], there seems to have been a passage leading to some other place. Whether this way the priests went into the hollow of the Sphinx."

This forced and extremely narrow passage subsists still at present, and terminates in a kind of niche. It could never lead to the Sphinx, because it is in the third part of the pyramid, above the horizon.

#### CARSTEN NIEBUHR (1761)

Captain of Engineers in the Service of the King of Denmark, *Travels through Arabia and Other Countries in the East*, trans. R. Heron (Edinburgh: 1792), 2 vols. [The journey commenced January 1761.]

Vol. 1, page 156

The famous Sphinx is sinking still deeper in the sand; and a great part of the body is already buried. It seems to be formed out of the rock upon which the pyramid stands; a circumstance which confirms my conjecture concerning the place from which the stones for building the pyramids were quarried. I found the chin of the Sphinx to measure ten feet six inches in height; and the whole length of the countenance nearly eighteen feet.

#### **CORNELIUS DE PAUW (1774)**

Recherches Philosophiques sur les Égyptiens et les Chinois (Paris: 1774), 2 vols.

Vol. 1, section 4, pages 258–59

Pierius says in the forty-ninth volume of his *Hieroglyphics* that it is very credible that Egyptian sculptors pretended to give to statues a great air of simplicity so as not to draw people into idolatry. Mr Winkelman [ Johann Joachim Winckelmann, the famous German art historian] even suspected that there existed in this respect an actual law, which impeded them at all times when it was a question of representing the human figure; meanwhile they were granted liberty without limit with regard to the representation of animals, among which he also counts the Sphinx, all parts of which he scrutinized with much more attention than Belon had done. And one knows that he discovered characteristic marks of both sexes, that is to say those of the lion, and those of the virgin, which were more to the front, toward the chest. This peculiarity, of which no one had been able to guess the reason until now, derived from the mystic doctrine, in which one showed that the divinity is hermaphrodite, letting everyone realize it was self-engendered; and the sphinxes are the emblem of the Divinity, whom the Egyptians never represented in the manner in which Eusebius described a statue of the god Cneph. Also, Mr Jablonski has proved that Eusebius was grossly mistaken in that.

## ABBÉ DE BINOS (1777)

Voyage par l'Italie, en Égypte . . . etc. (Paris: 1787), 2 vols.

Vol. 2, page 5 [Letter 53, about the Pyramids]

... they [tombs] are about 20 paces from one another, and have at their back a sphinx of which the head is raised more than 20 feet above the sand: the rest of the body, which is said to be more than 100 feet long, is buried in the sand.

## CLAUDE-ÉTIENNE SAVARY (1785)

Letters on Egypt, trans. Anonymous, 3rd ed. (London: 1799), 2 vols.

Pages 234-35

Opposite the second [pyramid], eastward, is the enormous sphinx, the whole body of which, as I have said, is buried in the sand, the top of the back only to be seen, which is above a hundred feet long, and is of a single stone, making part of the rock on which the pyramids rest. Its head rises about seven and twenty feet above the sand. Mahomet has taught the Arabs to hold all images of men or animals in detestation; and they have disfigured the face with their arrows and lances. Pliny pretends the body of Amasis was deposited within this sphinx. Many authors believe the well of the grand pyramid ended here, and that the priests came here, at certain times, to deliver their oracles; but these are mere conjectures. (*Note:* They bring the cavity on the top of the head of the sphinx, through which the priests delivered their oracles, as a proof of this opinion; but this cavity is only five feet deep, and neither communicates with the mouth nor the body of the sphinx.)

M. Paw [Cornelius de Pauw, see extract on page 488] (*Recherches Philosophiques sur les Égyptiens et les Chinois*) says, these sphinxes, the body of which is half a virgin, half lion, are images of the deity, whom they represent as a hermaphrodite; which opinion seems not to me more happy than that concerning the sepulchre of Osiris.

[See page 229, where he criticizes the opinion of de Pauw that the Great Pyramid was the Tomb of Osiris and says sarcastically that de Pauw "in his closet sees better than travelers."]

#### **COLONEL COUTELLE (1798)**

"Observations sur les Pyramides de Gyzeh," in Description de l'Égypte (Paris: 1818)

Vol. 2, pages 52–53

## The Sphinx

It is in one of the faults of the Libyan hills, in the area which rises toward the west across the plain, that the Sphinx has been carved; its height is about 13 meters [40 feet] above the actual ground, it remains like a witness and like a mass of stone raised up which has been superficially made to decorate this part of the hill. The rump, scarcely perceptible, seems only traced in the earth, with a length of almost 22 meters [72 feet]; and the side that we wanted to discover in clearing away the sand that the winds had accumulated up to the level of the hill presented no regular shape to us to a depth of approximately 9 or 10 meters [30 feet]: as to the hole which had been noticed on the [top of the] head, it is not deeper than 2 meters 924 mm [9 feet], of a conical and irregular shape.

## VIVANT DENON (1798)

Voyages dan la Basse et La Haute Égypte Pendant les Campagnes de Bonaparte, en 1798 et 1799 (London: [although in French], 1807), 2 vols.

Vol. 1, page 98

I didn't have time to examine the Sphinx, which merits being sketched with more scrupulous care, and which has never been done in this manner. Although its proportions are huge, its contours, which have

been retained, are supple as well as pure. The expression of the face is sweet, gracious, and tranquil; the character of it is African, but the mouth, of which the lips are thick, has a softness of movement, and both have a truly admirable finesse of execution. It gives the impression of flesh and of life. . . . [The rest of the paragraph is purely an artistic description.]

#### **JOSEPH GROBERT (1798)**

Description des Pyramides de Ghize (Paris: 1801)

Pages 31–34

Now we must leave the place far from the pyramids and go down toward the east. One follows the plateau; one passes in front of the meridianal [north] face of [the Pyramid of ] Chephren, and one moves off from it as far as one can to the right. One goes down quite a gentle slope to find the Sphinx, almost entirely covered by sand, and of which the projecting head is concealed from the eye by the unevenness of the ground.

[Count Constantin-François de] Volney, the only author worth quoting when you want to recount a sound idea about this region, has rightly observed that the completely Ethiopian profile of the Sphinx bears witness, in an authentic way, that that nation has given the Egyptians its laws, its morals, and its religion. These last are no more than a colony descended from Sennahar and some vast regions that encompass Nubia; they have deteriorated by mixing with the Arabs. The foreigners who can stand the disgusting sight of the Hokheila [evidently, a slave market] where Negroes are sold, will not find much there to resemble the profile of the Sphinx.

This monstrous statue, truly colossal, has been sculpted from a protruding piece of rock on which it sits. It is from a single piece. The quality of the stone perfectly resembles the rock itself, despite being painted yellow, and the color has been conserved up until our day in the places where it has not been damaged. Paintings found in Upper Egypt attest [to] the talent of the Egyptians in composing colors and the influence of the dryness of the climate in preserving them.

The Sphinx is actually very dilapidated, much more than it was in 1738, when [Friderik] Norden drew it. I uncovered enough of its back to measure it. But there should be a very considerable excavation to uncover it entirely. [This finally happened in 1817.] If one climbs onto the head, one sees a hole that is 15 inches in diameter at its widest point, and about 9 feet in depth. The direction is oblique. One sees that the depth has been diminished by stones, which have been thrown down into it. It would be difficult to determine the use of this cavity, unless one presumes some underground passage which this passage leads to, and that the priests hidden in this place delivered their oracles from it. The Sphinx was definitely an idol, and the tutelary divinity of this cemetery. The placement of the surrounding sand makes one suspect that the plain, which is at the foot of the rock to the south, and which is more elevated than the usual flood level of the river, is equally strewn with tombs. A little to the southwest is a tomb where a Turkish hermit lives, a chapel around which several trees have been planted.

# ACCOUNTS OF THE SPHINX FROM 1800 TO 1837

#### WILLIAM HAMILTON (1801)

Remarks on Several Parts of Turkey. Part 1. Aegyptiaca, or, Some Account of the Antient and Modern State of Egypt (London: 1809)

Pages 323-24

Where the causeway [leading from Cairo to Giza] ended, we crossed a larger and deeper canal, which we could plainly ascertain to be the line of communication still kept up from the Bahhr Jousouf [the ancient Bahr Yusuf Canal, which runs west of and parallel to the Nile] along the skirts of the Desert under [at the edge of the plateau of ] the pyramids, to join the canal of Terram, or the Bahhreiré. Herodotus evidently alludes to this navigation, when he says that, during the inundation of the Nile, boats coming from Canopus or Naucratis [cities on the Mediterranean coast] to Memphis [which is beside Giza] skirted along the Desert and the pyramids, in order to avoid the rapid currents of the main stream.

Pages 329-30

A large and strong built causeway [the Causeway of Chephren] has been carried from the entrances of each of these enclosures [the funerary temples in front of the Pyramids of Mycerinus and Chephren] to the celebrated sphinx, whose enigmatical meaning still continues to puzzle the antiquaries of Europe, and who has proved during a long lapse of ages the faithful depository of the mysteries which envelop every object round her. The French excavated the body of the lion; which they found uninjured: but the sands of the Desert very soon rendered their labour vain, and the last time I saw the sphinx, the head and neck alone were visible. These have been evidently painted all over, and many characters are to be traced upon the head-dress; but we could not ascertain whether they were the sacred or popular letters of Egypt [i.e., hieroglyphics or hieratic writing]; some indeed bore a resemblance to the Arabic. It is still a point of dispute among the learned, whether this combination of the human and the lion's form is typical of the rising of the Nile, the summer solstice, or the wisdom and power of the deity. Such a personification of human intelligence and brutal force might be the original of the Greek Minerva; and agreeably to this supposition, the sphinx is a very common ornament of this goddess on her statues and on her medals.

*The History of Egypt* (Edinburgh: 1805), 3 vols. [Wilson seems to have been an armchair scholar.]

Vol. 1, pages 93–94

As the sphinx is a monster in shape, so, among the Egyptian ruins, it appears to have been sometimes represented as of a monstrous size. In this situation it appears in the neighbourhood of the largest pyramid of Giza. Conjecture, among its various efforts, has suggested an idea, that secret passages were originally formed between the sphinx and the pyramids, and that the whole of these communicated with secret apartments in the rocks below. But the chambers in the only pyramid which has been examined [the Great Pyramid was then the only one open], are so small in comparison to the mass of the buildings, that there is scarcely room to suppose, that these contrivances had any religious, or highly important, connection with subterranean abodes or apartments in the rock.

[Here he gives a footnote reference to Thomas Shaw's *Travels*, pages 421–22. There is no indication that Wilson ever visited Egypt, and he gives no eyewitness account of the Sphinx.]

#### EDWARD DANIEL CLARKE (1810 AD)

Travels in Various Countries of Europe, Asia and Africa (London: 1810–1823), 3 vols.

Vol. 3, part 2 (1814), pages 127–28

#### PART THE SECOND. Greece, Egypt and the Holy Land

Upon the south-east side is the gigantic statue of the Sphinx, the most colossal piece of sculpture which remains of all the works executed by the Antients. The French have uncovered all the pedestal of this statue, and all the cum-bent [recumbent] or leonine parts of the figure; these were before entirely concealed by sand. Instead, however, of answering the expectations raised concerning the work upon which it was supposed to rest, the pedestal proves to be a wretched structure of brickwork, and small pieces of stone, put together like the most insignificant piece of modern masonry, and wholly out of character, both with respect to the prodigious labour bestowed upon the statue itself, and the gigantic appearance of the surrounding objects.

Page 145

We then descended into some of the smaller sepulchres. The walls of these were adorned with hieroglyphics. In some instances, we noticed the traces of antient painting, an art that seems to have been almost coeval with the human race. The most remarkable instance of this kind was discovered by the author in a situation where, of all others, it was least expected, upon the surface of the Sphinx. As we drew near to view this prodigious colossus, a reddish hue was discernible over the whole mass, quite inconsistent with the common colour of the limestone used in building the Pyramids, and of which the Sphinx itself is formed. This induced us to examine more attentively the superficies of the statue: and having succeeded in climbing beneath the right ear of the figure, where the surface had never been broken, nor in any degree composed by the action of the atmosphere, we found, to our very great surprise, that the whole had once been painted of a dingy red or blood colour, like some of the stuccoed walls of the houses in Pompeii and Herculaneum.

[He goes on to give Coptic and Arabic inscriptions that he found on the Sphinx, now vanished.]

#### THOMAS LEGH, M. P. (1813)

*Narrative of a Journey in Egypt* (London: 1816)

Page 23

On our descent [from the top of the Great Pyramid] we breakfasted at the base of the Pyramid, and after admiring the graceful outline of the Colossal Sphinx, returned to Cairo, which we reached by two o'clock the same day.

#### ROBERT RICHARDSON (1817)

Travels along the Mediterranean and Parts Adjacent (London: 1822), 2 vols.

Vol. 1, pages 153–57

. . . we proceeded next morning to take a view of the sphinx. . . . It stands a little to the east of the two last-mentioned pyramids, and on a much lower level. The lower part of this venerable piece of antiquity, which had for ages lain buried under a load of sand, had been a few months before uncovered by the exertions of Captain Caviglia, with the assistance of the two gentlemen before mentioned; at the time, however, that we visited it, the Arabs and the wind had replaced the greater part of the covering, and the lower extremities of the sphinx were equally invisible as before his operations. The breast, shoulders, neck and head, which are those of a human being, remain uncovered, as also the back, which is that of a lion; the neck is very much eroded, and, to a person near, the head seems as if it were too heavy for its support. The head-dress has the appearance of an old-fashioned wig, or periwig, projecting out about the ears, like the hair of the Berberi Arabs: the ears project considerably, the nose is broken, the whole face has been painted red, which is the color assigned to the ancient inhabitants of Egypt, and to all the deities of the country, except Osiris. The features are Nubian, or what, from ancient representations, may be called ancient Egyptian, which is quite different from the Negro feature; the expression is particularly placid and benign, so much so, that the worshipper of the sphinx might hold up his god as superior to all the other gods of wood and stone which the blinded nations worshipt. The whole of it is cut out of the rock, which is calcareous, easily sectile, and abounding in small bivalve shells; and probably the large excavations in front, and on each side of it, furnished part of the stones for the building of the pyramids. There was no opening found in the body of the sphinx, whereby to ascertain whether it is hollow or not. The back is about 120 feet long; the elevation of the head from 30 to 35 feet above the sand; the paws were said to stretch out on the platform in front of it to the distance of 50 feet. Between the paws were found the remains of a trilithic temple, adorned with hieroglyphics. In front of the temple was a granite altar with four horns, one of which remained, and the marks of fire, from the burning of incense, were visible upon it. Several Greek inscriptions were found on the paws of the sphinx, but none of them older than the second century: one of them is signed Arrianus and is merely an address of the poet of that name to the sphinx as the guardian genius of the king of Egypt . . . . [a section describing what Caviglia found is omitted here and also below] . . . The Arabs calls the sphinx abou el hol, the father of terrors, or abou el haoun, the father of the column, which last seems to favour the above supposition [about a column]. . . . Herodotus makes no mention of this enigmatical figure, yet it is completely Egyptian, and from the great disintegration that it has suffered, we can hardly suppose that it did not exist in his time. Pliny, who is the first author that mentions it, merely states its position in front of the pyramids, and that the inhabitants said it was the tomb of king Amasis, and was brought there, which he contradicts, by asserting it to be cut out of the rock; but offers no conjecture of his own as to its use or formation. . . . The countenance of this sphinx, however, was that of a man [contrary to the Greek tradition that a sphinx had the head of a woman]. The red colour does not sufficiently characterize the sex, but the beard, which was found between its paws, leaves little doubt on that subject. The expression of almost all the Egyptian figures is so particularly mild and interesting, that without the accession of the beard, they might all pass for females. This figure was entire in the time of Abdallatif, who describes its graceful appearance and the admirable proportion in the different features of its countenance, of which, he particularly mentions the nose, the eyes, and the ears, and says that they excited his astonishment above every thing that he had seen in Egypt; and Makrisi states, that it was mutilated by Sheik Mohammed, called the faster [meaning "fasting from food"] of his time; the same ravenous animal who mutilated the lions that adorned the bridge at Cairo, and who deserved to be a relation of his savage namesake, who attempted to demolish the pyramids, if he were not the identical animal himself.

#### CHARLES LEONARD IRBY AND JAMES MANGLES (1817)

Travels in Egypt and Nubia, Syria, and Asia Minor during the Years 1817 & 1818 (London: 1823). Photographic reprint by Darf Publishers Limited (London: 1985)

Pages 155-58

Wednesday, September 1 [1817]. Our first care now was to shave our beards, which we had allowed to grow from our first departure from Philae, and resume our European costume; we felt as awkward at first at this change of dress, as we did when we first assumed the Arab costume. Mr. [Henry] Salt [the British consul-general in Cairo] received us very civilly. We found that great discoveries had been made at the pyramids and sphinx during our absence; and the first thing that drew our attention was Mr. Salt's elucidative plan of the pyramids, sphinx, and all their interesting environs. As the whole account of the proceedings is going home for publication, I shall only trouble you with a few particulars. On our arrival we found, at Mr. Salt's house, Colonel Stratton, of the Enniskillen dragoons, and Mr. Fuller: these two travellers had come from making the tour of Palestine, having lastly arrived by land from Yaffa and Gaza. They embarked at Constantinople, having first made the tour of Greece. As they had not yet been to the pyramids, we were glad to have an opportunity of accompanying them.

Friday, September 4. We went early in the morning, and Mr. Salt having lent us a copy of his newly made plan, we regularly went over the whole neighbourhood, place after place, according to the plan; we found there was nothing new for us to see, excepting a few of the upper steps fronting the sphinx. Unfortunately for us and all future travellers, they have filled up all the excavations of the sphinx, so that there is not so much to be seen now, as there was previous to our departure, the base having been perfectly cleared on one side, before we started for Upper Egypt. From the several drawings and plans which we have seen, together with the description we have heard, it appears that the indefatigable Captain Caviglia continued his operations till he had cleared all the breast of the animal; that he afterwards pursued his labours till he reached the paws, at fifty feet distance from the body; and here it was, between the two, that he discovered a small temple, views of which are given in this work. I imagine this small edifice was composed of three large, flat stones, like a similar shrine in the possession of Mr. Salt, and that the door was filled up by two smaller pieces of stone on each side of it; these sides have some fine specimens of basso-relievo, and give a fine idea of what

the sphinx originally was. A man is depicted as presenting an offering to it; some inscriptions also are interesting, and one of Caracalla has the name of Geta, his brother, erased, as in the Latin inscription at Syene. The lions which were found, together with the tablets, in basso-relievo, have been sent home to the British Museum, where I hope you will see them. The great head of Memnon will please you, and when you contemplate its grandeur, recollect that Thebes has at present the remains of thirtyseven statues of equal dimensions; many greater. Beyond the small temple is an altar. To describe the other parts, I must beg you to imagine yourself fronting the face of the sphinx, at a considerable distance, and nearly on a level with the lower part of the face, and also with the ground adjoining the animal. As you advance, you find at some distance from the paws, a flight of steps which lead some depth below the paws to the base of the temple. Mr. Salt is of opinion that this descent by steps was meant to impress the beholder (after having first viewed the sphinx at a distance on a level) with a more imposing idea of its grandeur, when he views the breast in its full magnitude from below. A wall of sun-burnt brick was on each side of the steps, to prevent the sand from filling up the space. Afterwards we went all over the great pyramid, again descending to the lower chamber, which Captain Caviglia discovered, and also reinspected the well, &c. We could not show them Colonel Davison's chamber, as the Arabs had stolen the rope ladder which was left there. After having slept at the mouth of the great pyramid, we returned to Cairo; the excursion occupied us two days. When we were last at Cairo, a trip to the sphinx used to take two hours; we were now five hours going there, the inundation of the Nile forcing us to go more than double the distance round the edge of the canals. We went in a cangia, or rowing boat, as the canal was quite full.

## COUNT DE FORBIN [LOUIS-NICOLAS-PHILIPPE-AUGUSTE COMTE DE FORBIN] (1817–1818)

Travels in Egypt, Being a Continuation of the Travels in the Holy Land, in 1817–18 (Second Part of Count de Forbin's Eastern Travels, Part One being Travels in Syria), issued, with Explanatory Notes in English (anonymous) as an offprint by the London Journal of Voyages and Travels, editor: Benjamin Bensley (London: September 1819)

Page 19

The colossal sphinx still rises thirty-eight feet above the sand that the winds from the desert are accumulating ahout it. My arrival was too late to avail myself of the labours of M. [Monsieur Henry] Salt. On clearing away about the base of this statue, he had found steps that communicated with the gates of a little temple erected between the feet of the sphinx. An unpardonable egotism led him to block up again objects which call for an active and vigorous investigation, which would throw great light on the history of the arts in ancient days, would bestow éclat on one of the most sublime monumental fictions to be found in ancient Egypt.

JAMES BURTON (1822)

From Burton's original unpublished manuscript in the British Library (MS. Add. 25,619, f. 32)

[Note: The spaces marked by ellipses below are words written in the manuscript in Arabic script, which I have not transcribed.]

## **Sphinx**

The Sphinx is still called Aboo l'hol, a name by which it was known among the natives 650 years ago, and would seem to strengthen the etymology chosen by M. [Louis] Langlès for the word Belheet . . . or Belhoobeh . . . or Belhooyeh . . . which Makreesy [the historian Taqiyyu 'l-Din al-Maqrizi (1364–1442)] and Syotty [the historian Jalalu 'l-Din al-Suyuti (1445–1505), who wrote a history of Old and New Cairo, among other works] give as the *true* one and which it seems according to M. [Silvestre] de Sacy is written thus in different copies and apparently also Belhoot, . . . according to M. Langlès, which he selects and says is compounded of the words . . . eye and . . . terror. The Arab name seems to be a translation of the Egyptian.

The countenance has yet the traces though faint of the red colour with which it was formerly covered, and which 6 or 7 centuries back, was coated with a varnish that then had all the brilliancy of freshness. The colour should certainly never be called *yellow*.

[He then quotes book 1, chapter 4 of Abdallatif about the Sphinx (see page 447) and Denon on the Sphinx (see page 489), and he makes some comments on Denon's artistic remarks, which I omit.]

The statue was mutilated by a bigoted enthusiast [old-fashioned term for a fanatic], Sheckh [Sheikh] Mohammed, about year of the Hegira—? [Burton left a blank for the date.] It was probably when the nose was thus broken that the Asp [uraeus] and headdress were removed. There is little doubt that it carried these ornaments, from the hole now remaining in the top of the head, which the natives have at some time or other enlarged, in the hopes of finding in the interior some hidden treasure. The head however is solid stone, and they soon found their labour useless. I think I remember Mr. [Henry] Salt having told me, that he found in excavating the temple between its paws, part of an asp in bronze. This will have been that placed over the forehead.

The rump was repaired with Mapara [?] stone probably by the Kornans [?]—their repairs were destroyed again by the late Defterdar in order to serve as building materials for one of his palaces.

Moorad Bey [Murad Bey (d. 1801); see his portrait in figure 2.8 on page 92] first uncovered the Sphinx but found nothing—he did not dig deep. The French then did it, and were equally unsuccessful. [Captain J.-B.] Caviglia finally succeeded, and the accompanying notice of the work is copied from the . . . [here the text breaks off ].

[The verso side of this manuscript leaf has Burton's copy of Henry Salt's plan of the paws and altar of the Sphinx, with identifying letters and specific descriptions. No succeeding leaf has been bound into this manuscript volume, and the subsequent leaves by Burton change subject.]

## JOSEPH MOYLE SHERER (1824)

Scenes and Impressions in Egypt and Italy (London: 1824)

Page 159

The Sphinx disappointed us; as it does generally, I should think: drawings and prints deceive wonderfully; it has neither the size, the majesty, or the sweetness with which it is usually represented.

Pages 149-53

Returning [from Saqqara], we again called on [Captain] Caviglia. Magic had been at work in his little

hut: plans and drawings were hung all round, concealing and ornamenting its walls; his books established on shelves and tables . . . He declined returning with us that evening to our boat, but said he would himself accompany us to Saccara [Saqqara] on the morrow, which he did. His wish was to show the interior of that pyramid (the same which the Arabs call the Seat of Pharaoh; and here, perhaps, tradition does not err; but the other pyramids are surely sepulchral) opened by the French, he having founded some opinion on the examination of it, which leads him to suppose, that *none of the pyramids were sepulchres*—I leave him to amuse himself with the difficulty. He is a kind man, with much enthusiasm about Egyptian antiquities, having exhibited enterprise and perseverance, and fearlessly expended all he could: he is unpretending too, considering his visit to Paris, and the nonsense he heard talked there about Moses and Orpheus, and which, at times, will peep from under his modest avowals, that he is only a sailor [his profession was naval captain], with a strong turn this way, which has made him both labour and read on antiquities. . . . . He showed, and with no little pride, a number of the Quarterly Review [volume 19 for 1818], which spoke of his labours with high praise and deserved encouragement. I borrowed the volume . . .

#### **RICHARD MADDEN (1826)**

Travels in Turkey, Egypt, Nubia, and Palestine (London: 1833), 2 vols.

## Vol. 1, page 257

In the time of Aaron Hill (upwards of one hundred and twenty years ago) there was no entrance into the interior [of the Chephren Pyramid, opened in 1817 by Belzoni]; and when Herodotus was in Egypt [his dates were fifth century BC] it was closed.

Aaron Hill asserts that he found a mummy in the sepulchral chamber of the large Pyramid, covered with hieroglyphics; and that from one of the galleries he made his way under ground to the interior of the great sphinx. This indeed savours of the marvellous [i.e., Madden thinks Aaron Hill made it up, which he certainly did; the publications of Aaron Hill on Egypt are entirely fictitious and were commercially motivated publishing hoaxes].

## Pages 260-62

More probably the use of the Pyramids was connected with the celebration of the mysteries of the Egyptian religion. The narrow oval apertures in the chambers of the pyramids, into which Caviglia thrust joined reeds eighty feet long, without finding any impediment [these are nowadays called the "ventilation shafts"], we know nothing of, or where they terminate. The secrets of the Egyptian religion, in my opinion, are only to be sought in the interior of the Pyramids. It is vain to look for them in the papyri found either in Thebes or Memphis. Hitherto [prior to 1826] all those which have been found have proved totally devoid of interest. Law processes, votive offerings, narrations of funerals, and title-deeds, are the only subjects of the papyri. Mr. Caviglia, with whom I lived for some months at Mr. Salt's, was strongly of this opinion: his valuable discoveries in the great Pyramid, of the passage of the well [the well shaft, which he was the first to clear of sand and rubble], and of the ruins of temples close to the Pyramids, were published in the Quarterly Review [vol. 19 for 1818]. How much it is to be regretted that commerce alone monopolizes all the enterprise of the affluent, and that no company of scientific men is to be found to invest a capital of five or six thousand pounds in the advancement of science. With such a sum, I believe the real knowledge of the Pyramids might be

attained; and so far as regards the religion and learning of the Egyptians, perhaps for the destruction of the Alexandrian library we might be almost compensated.

I would carry on the excavation of the Pyramids both from the upper chamber and the body of the sphinx, in the direction of the base of the pyramid, at about the same monthly expense as Belzoni in 1817; and in the course of a few years, nay months, I am much deceived if nothing should be discovered to redeem the wisdom of the Egyptians from the libel of having constructed a mountain of infamous architecture, like that of the great Pyramid, containing only two insignificant chambers for the accommodation of the corpse of a tyrant.

#### JAMES WEBSTER (1828)

Vol. 2, page 22

We at length entered the desert, and in a few moments stood before the Sphynx. The ridge of the back is seen rough and time-worn; the head dress is made to project behind so as to counterbalance the chin and face; in front, between the paws, a temple has been discovered, for a drawing of which, see No. 38 of the Quarterly Review. [This engraving is reproduced as figure 3.3 on page 132. The sand has now covered up the temple, and in time the head only of the Sphynx will be visible, as before. Much has been done to prevent this by Mr. Caviglia, who erected a wall around his excavations; but the position of the Sphynx, considerably below the level of the pyramids themselves, heaped up a hundred feet by the sands, renders all attempts of this kind hopeless. No effort can save the excavation from being filled up by the sands.

## Page 24

The sands have made irresistible progress in the course of ages. The pyramids were, no doubt, on the bare rock: the body of the Sphynx must have also been uncovered. Now, not only are these encumbered, but the rocks, and all along the edges of the fields below them, are covered with the sands—the tide of an ocean that shall never know reflux!

## SIR JOHN GARDNER WILKINSON (1835)

Topography of Thebes, and General View of Egypt (London: 1835)

## Page 331

The Sphinx stands nearly opposite the south-east end of the pyramid of Chephren. Between its paws were discovered an altar and some tablets, but no entrance was visible. Pliny says they suppose it the tomb of Amasis; a tradition which arose, no doubt, from the resemblance of the name of the king, by whose order the *rock* was cut into this form, Thothmes IV [1425–1417 BC], to that of the Saite monarch. [There was a king Amasis (570–526 BC) of the Twenty-sixth Dynasty, known as the Saite Period; Wilkinson is proposing that the two became confused in later tradition.] But one author [he refers to the Roman poet Lucan] has gone farther, and given to Amasis the pyramids themselves. The cap of the Sphinx, probably the pshent, has long since been removed; but a cavity in the head attests its former position, and explains the mode in which it was fixed. The mutilated state of the face, and

the absence of the nose, have led many to the erroneous conclusion that the features were African; but by taking an accurate sketch of the face, and restoring the Egyptian nose, any one may convince himself that the lips, as well as the rest of the features, perfectly agree with the physiognomy of a Pharaoh; for the reader must be aware that this and all other sphinxes are emblematic representations of Egyptian kings.

[Wilkinson adds in a footnote: "From the name and hieroglyphics on the tablet in front of it, we may conclude it is of Thothmes IV."]

#### Page 38

[In his journey to Giza on December 31, 1835, Stephens noted this about the Sphinx:]

Next to the pyramids, probably as old, and hardly inferior in interest, is the celebrated Sphinx. Notwithstanding the great labours of Caviglia, it is now so covered with sand that it is difficult to realize the bulk of this gigantic monument. Its head, neck, shoulders and breast are still uncovered; its face, though worn and broken, is mild, amiable, and intelligent, seeming, among the tombs around it, like a divinity guarding the dead.

## Vol. 1, page 242

In the face of the scarped rock, about a quarter of a mile to the south of the great pyramids, is a Hypogean temple, the entrance of which is also decorated with figures and hieroglyphics. The Arab guides were averse to my entering it. . . . The great Sphynx is to the eastward of this temple; no part of it but the head could be seen, the sand drifts so constantly upon it. It stands on a much lower level than the pyramids.

#### EXCAVATIONS OF MONSIEUR MARIETTE AT THE GREAT SPHINX

We have already announced the important communications made by Monsieur Auguste Mariette of the Academy on the subject of the excavations at the Serapeum of Memphis. Lack of space prevents us from going into this subject in great detail, and especially of speaking about the excavations that have taken place at the Great Sphinx. In 1833 an English Egyptologist, Mr. [Charles H.] Cottrell, to whom one owes the translation of the work of Monsieur Bunsen [Baron Bunsen, i.e. Christian Carl Josias Freiherr von Bunsen] on Egypt [Egypt's Place in Universal History (London: 1848), 5 vols.], found in Florence among the papers of Caviglia, who undertook the first of the extensive excavations around the colossus [the Sphinx], the plan of the two chambers discovered behind the Sphinx, which contained hieroglyphic texts. Monsieur [Samuel] Birch had the thought that if one succeeded in rediscovering these two chambers, the inscriptions in question would reveal the origin of the gigantic statue. M. le Duc de Luynes [Louis-Charles d'Albert, duc de Luynes], alerted to this fact by M. [Vicomte Emmanuel] de Rougé, wished, with his well known liberality, to help our compatriot to pursue this curious quest, and furnished him with the funds necessary for the excavation. This act of generosity was soon followed by an allocation of funds from the French government, and Monsieur Mariette came to clear the Sphinx, which he found to be only a natural rock of which the art of the ancient Egyptians had, so to speak, finished the shapes in order to make the statue of a god. That god is Horus, and the temple where he was worshipped has been rediscovered to the southeast of the colossus [Sphinx; this temple is now called the Valley Temple]. It is an enormous square enclosure comprising a crowd of rooms with galleries made of gigantic blocks of alabaster and granite. This edifice, completely devoid of hieroglyphic inscriptions, like most of the monuments dating from the most ancient pharaohs, dates, according to all probability, from the Fourth The Egyptians had sculpted the head of the Sphinx and filled up the large natural hollows and molded the shapes with masonry. This colossus is found at the bottom of a sort of pit of which the lateral walls are 20 meters [66 feet] away from each of its sides. Monsieur Mariette admits that in antiquity the water of the Nile could have entered this pit. Later, the Greeks had built the steps discovered by Caviglia for going down into the pit. Against the right side of the Sphinx the traveler had found a huge Osiris statue made of 28 pieces, reckoned to be the number of pieces into which the body of Osiris had been cut according to the Egyptian myth.

The Sphinx has been measured in all of its dimensions. Its height is 19.7 meters [64.6 feet]. In the back and across the hindquarters of the statue, Monsieur Mariette recognized the vertical shaft, the existence of which had previously been pointed out by Vansleb [ Johann Wansleben] and [Richard] Pococke, who thought that one could penetrate further down from there into existing chambers, according to their supposition, inside the colossus. This shaft, explored with care, presented at its bottom a roughly hewn room, which was in reality just a natural fissure enlarged by the hands of man. In this room lay some fragments of wood that gave off a strong smell of resin when burned, which led one to believe that the wood came from a sarcophagus.

One had supposed that in antiquity the Sphinx was entirely painted red, but nothing indicates that this had been so. Only the face was once covered in this color after the reign of Rameses the Great, for in the time of that pharaoh, the beard of the colossus represents an act of worship over which the red had been applied.

The Greek inscriptions found near the stairs of the Sphinx tell us that this colossus bore the name of Harmakhis, the significance of which has still not been discovered.

The excavations of the Great Sphinx did not lessen the honor due to the intelligence and to the devotion of Monsieur Mariette in his magnificent discovery of the Serapeum [at Saqqara]. We need to return to this archaeological event before recapturing, as we will be doing in one of the forthcoming issues, the analysis of the works of the Academy since our last survey.

# CONCERNING THE AGE OF THE SPHINX AT GIZA

## LUDWIG BORCHARDT

TRANSLATED BY ROBERT TEMPLE AND ELEONORE REED

Ludwig Borchardt, Berlin, submitted by Herr Erman*Sitzungsberichte der Königlich Preussischen Akademie der Wissenschaften zu Berlin* [Report of the Proceedings of the Royal Prussian Academy of Sciences at Berlin], Sitzung der philosophisch-historischen Classe [Proceedings of the Historic-Philosophical Class], vol. 35 (1897)

#### Pages 752-60

The question concerning the date of origin of the Great Sphinx at Giza, approached from a different direction than has been done heretofore, shall be the task of the investigation that follows. The previous investigators have been guided in their opinions either by the mention of the name Chephren in the Sphinx stela of Thutmosis IV [the "Dream Stela"], or they have imagined that they saw some similarities in the type of the countenance of the Sphinx itself, and have arrived at differing conclusions among themselves. It is precarious, to say the least, to attempt to maintain the first approach, which concerns the name of Chephren, since the inscription referred to speaks of nothing more than a name adjoining a large gap in the surrounding passage of text, possibly completed as Chephren [only half of the name is preserved, and the rest has flaked off], in combination with some statue. It is not at all clear that the Sphinx is somehow referred to here. The second approach, which presumes to elicit something from the type of countenance, is even more uncertain; the face is so ruined that unless some other indices can be added to this, one can scarcely infer anything from it.

In what follows an attempt shall be made to arrive at a date based on details of dress, since for the present that seems to be the only safe way to date Egyptian sculptures, whereas for the treatment of such questions from the purely stylistic point of view there exists up to now neither sorted material nor sufficient preparatory work. We must for the moment content ourselves in the research that confronts us with settling the question solely as a matter of dress, by setting strictly aside all stylistic observations relating to the treatment of the actual portrait, the musculature and so forth, and thus reducing the question to something visibly obvious and tangible—or, I might even say, numerical.

The first criterion of this kind with which we shall deal concerns the eye-paint stripes which are found projecting from the outer corners of the eyes of the Sphinx in entirely flat relief and with traces of blue pigment. Regarding these, we should need to apply the law, recently discovered by Herr [Baron] von

Bissing, that eye-paint stripes were unknown in the Old Kingdom. That this is so is shown by the following statistics, which unfortunately only refer to what is in the Cairo Museum, but which could hardly be modified by objects from other collections.  $^{*4}$ 

The Cairo Museum possesses in its Old Kingdom halls and storage areas over 230 statues and fragments of statues with heads which date from the Old Kingdom [this was in 1897]; none of these have any eye-paint stripes. In this account the following are not counted:

- Fourteen statues of kings which bear the names of ancient kings are exhibited in the Old Kingdom halls, but on many grounds which would take too long to discuss here, these can in no way be viewed as works of such an early period; further
- Three painted wooden statues (Numbers 289–311, Catalog 1895, page 28,Hall 11, Case A) from Akhmim and Luxor which are placed by mistake in the halls of the Old Kingdom, but are not ascribed to the Old Kingdom, and
- One torso of a queen (Number 255, Catalog 1895, page 15, Hall 3, Case B) found at Abydos by Mariette, which he affirmed (Mariette, Catalog Number 516) might perhaps be the oldest of Egyptian art, but which contemporary art historians date either as Ptolemaic or Roman.

All of these\*5 show the eye-paint stripes, and so they should, because none of these sculptures belongs to the Old Kingdom.

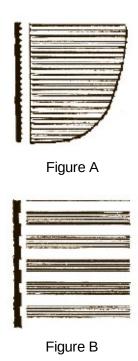

Only a single statue that can with certainty be dated from truly ancient times shows eye-paint stripes; it is a painted wooden statue found at Meir of a standing naked girl, perhaps a dancer (Number 248, Catalog 1895, Supplement 2, Number 1340b, Hall 2), which is placed together with the contents of the grave of Pepy-nonh-kem in the same display case, but differs from the works in this grave find, so that the possibility cannot be discounted that it may have been reckoned among these grave goods in error. If we discount this possibility, we have the first appearance of eye-paint stripes during or after the Sixth Dynasty, which was the time when all the radical changes in dress and customs appeared, which separate the Middle Kingdom from more ancient times, so that certainly in terms of the history of art, but perhaps also in the political sense, one can properly speak of the Middle Kingdom having begun with the Sixth Dynasty.

What we have ascertained from the statues is shown also by the reliefs. Prior to the Sixth Dynasty, eye-paint stripes cannot be demonstrated anywhere, but thereafter they make their appearance everywhere: thus, they appear on the *udjat* eyes on the stelas, on coffins, in grave paintings, and even in the [hieroglyphic] sign in the writings.

A single plausible exception is known to me: on the false door of the grave of Schery (Giza, Catalog 1895, Number 13, Hall 1, from Saqqara) one of the women, if one looks really closely, has eye-paint stripes on her eyes, although none of the other figures bears any sign of any. Even though Schery was a priest of the kings Send and Peribsen of the Second Dynasty, the false door does not yield any signs that it also dates from such ancient times. It reminds us rather of the works from the end of the Old Kingdom, especially where the style of the sunken hieroglyphics is concerned. Therefore I believe that, at least until the opposite can be proved, one has to come to the following conclusion: the makeup stripes appear, at least where statues are concerned, at the earliest during the Sixth Dynasty, but become more widespread only during the Middle Kingdom.

Now, the Great Sphinx has obvious eye-paint stripes. Therefore the time of its creation falls into the period subsequent to the Sixth Dynasty.

Just as this criterion has given us the lower date limit, so we can find the upper limit in the ornaments of the headdress, the so-called King's Bonnet. This decorated piece of cloth lying over the forehead with the uraeus, which is the symbol of the kings, is tied firmly to the forehead with a headband. It frames the face, creating two triangular areas which fall in two pleats on either side of the face, down the neck, and onto the chest. At the back it is gathered together and ends in a plait lying down the back, which is ribbed as well as appearing to be wrapped. The pattern that this scarf shows is in most cases the following: the front folds are, as shown in A, both in frontal view and also in section, folded into horizontal pleats, the piece covering the head, however, is divided into regular alternately sunken and raised stripes (figure B), which with statues of which the painting is still showing, is depicted in alternating yellow and blue shades.

This King's Bonnet was of course fashion-dependent, and so we can at least in the statues follow different variations through time. From the Eighteenth Dynasty, or perhaps even a little earlier, it becomes fashionable to supply the inside with a vertical smooth hem.\*6 Around the Nineteenth Dynasty, it becomes common practice to extend the regular division of the stripes of the upper part of the front pleats to the chest by giving up the pleats,†7 and at the same time they now divided the ribbed plait instead into sunken or raised horizontal stripes.

The Great Sphinx of Giza also shows yet another pattern in its headdress. The stripes of that headdress given as sunken are arranged in groups of three stripes each, that is, one wider stripe is always placed between two narrower stripes. Each of the wider stripes has on either side a small accompanying stripe. And this differs from the usual arrangement with stripes of equal width. And therefore we also have to examine where and when this anomaly occurs.

The following list, which shows those kings' statues with the stripes that are grouped in this manner,\*8 will show this immediately. We must distinguish between two different forms: those with completed groups (figure C) and those where they are only indicated in simple lines (as in figure D). Both types of course belong to the same type; the second is only an abbreviation of the first.

Figure C

Figure D

In the museum at Giza I could make the following observations:

- 1. Number 384 (Catalog 1895, Number 125, Hall 16). Torso of a statue of the Twelfth Dynasty, usurped and reused by Merenptah-Hetep-her-maat. Cap stripes of type C.
- 2. Number 385 (Catalog 1895, Number 1370, Hall 16). Statue of Amenemhet III. Stripes of type C.
- 3. Number 430 (Catalog 1895, Number 226, Court 28). Statue of the Twelfth Dynasty. 19
- 4. Number 432 (Catalog 1895, Number 196, Hall 26). Statue of the Twelfth Dynasty, usurped and reused by Ramesses II. Stripes as in C.
- 5. Number 481 (Hall 63, Cabinet A). Head of the type of Amenemhet III. \$\frac{\pma10}{2}{2}\$ Stripes as in C.
- 6./7. Numbers 482/3 (Hall 63, Cabinet A). Two heads of the type of Amenembet III. Stripes as in D.

In the Berlin Museum, at my request Herr Shaefer was so kind as to check through the originals and casts:

- 8. Number 1121 (Catalog, page 331). Statue of Amenemhet III, usurped and reworked by Merenptah. Stripes as in C. The stripes of the apron show the same pattern.
- 9. Number 7264 (Catalog, page 24). Statue of the Twelfth Dynasty, usurped and reused by Ramesses II and Merenptah. Stripes as in C.
- 10. Number 11,348 (Catalog, page 58). Upper part of a statue of the type of Amenemhet III. Stripes as in D.
- 11./12. G. 388/9. (Catalog, page 331). Casts of the statue of Amenemhet III at St. Petersburg, with reference to this type (see Golenischeff in *Recueil de Travaux*, 1893, plates 1–3). Stripes as in D.

In Paris, where again I owe the material to Herr [Heinrich] Schaefer, we find only one such statue:

13. Number 23 (de Rougé, *Notice des mon.*, page 22). Sphinx of the Twelfth Dynasty of Apophis, later usurped by Merenptah-Hetep-her-maat. Stripes as in C. [Translator's note: This is the Sphinx of Amenemhet II, which is discussed at length in chapter 4 of this book and is identical with the face on the Great Sphinx of Giza. It should be noted that Borchardt had not seen this sphinx A23 personally but had merely received information from Heinrich Schaefer that it had the correct pattern of stripes. Nor was a photo of it supplied to Borchardt, or he would probably have recognized the face instantly.]

In London, where Mr. Griffith has kindly checked through the available material, there seemed to be in the Museum no statues which could be used here as examples.

In England in private ownership we find:

- 14. Head of the type of Amenemhet III in the Grenfell Collection (Burlington Fine Arts Club, the Art of Ancient Egypt, 1895, photo number 51). Stripes as in D.
- 15. Head of the type of Amenemhet III, owner unknown (op. cit., photo number 43). Stripes as in D.

Of the other collections, I have checked through the photographs, which are kept in the Berlin Museum, but have not found any further cases of the order of stripes that we are discussing here. So the result of this compilation is clear:

The grouped stripes on the King's Bonnet are only found during the Twelfth Dynasty, perhaps only under Amenemhet III, because those pieces that are precisely dated and that have such an arrangement of stripes are all from his time. And of the others, which are only dated generally to the Twelfth Dynasty, it can never be discounted that they also might be images of Amenemhet III. For this more narrow limitation of this fashion of stripes to the time of Amenemhet III speaks as well as the circumstance that the statues of Usertsen from Lisht (Giza, Numbers 411–20, Catalog 1895, Supplement 3, Number 1365, Hall 21) have not grouped but merely regular stripes [see figure 4.18]. But whether or not one wishes to limit the time of the grouped stripings to the reign of Amenemhet III, one thing is for certain: after the Twelfth Dynasty, this fashion has vanished. The statues of the Thirteenth Dynasty, Sebekhotep (Louvre, Cast G 1, Catalog S. 332, Berlin) and Sebek-em-sa-f (Giza, Number 386, Catalog 1895, Number 128, Hall 16), already display the regularly striped King's Bonnet.

So for the dating of the Sphinx at Giza we draw from all of this the following conclusion: Because the headdress of the Sphinx shows the wide stripes with the narrow accompanying stripes, the Sphinx therefore can surely not have been created after the Twelfth Dynasty.

We have now enclosed the origin of the Sphinx within two limits, an upper and a lower.

According to the makeup stripes, it is Sixth Dynasty or later. According to the stripes on the headdress, it is before the end of the Twelfth Dynasty. If one wishes to be less cautious, one can add to this perhaps the time of Amenemhet III.

For this dating, we can also add some other minor facts to which we do not however wish to attribute too much weight:

- The lack of any mention of the Sphinx in the Old Kingdom, as far as we know from any inscriptions discovered up till now.
- The lack of finds from the Old Kingdom in the immediate vicinity of the Sphinx.

- The occurrence of two vertical shafts on the back of the Sphinx, one of which ends in a burial chamber, in which coffin boards have been found.\*\*11 From this we can infer the earlier existence of a mastaba on the back of the Sphinx.
- The original beardlessness of the face, \*12 exactly as Amenembet was usually depicted.
- The occurrence of a divine image in front of the chest of the Sphinx between its paws, exactly as with the Middle Kingdom sphinx from El Kab (Giza, Number 391, Catalog 1895, Number 139, Hall 16). The traces of this divine image are still clearly visible in front of the chest as a protruding piece of stone.

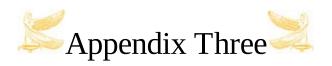

Finally, if one really wants to, one could even read the type of Amenemhet III's face into the countenance of the Sphinx. But as I have said already in my introduction, this is a rather questionable argument because of the destruction of the features.

One could imagine the history of the Sphinx in general, mixed with some guesses, in the following manner:

The Sphinx was hacked out of the bedrock, perhaps by Amenemhet III, by destroying one of the mastabas standing on a hill, which now constitutes the back of the Sphinx, and partly by building it up with ashlar blocks. It shows the king in the shape of a prostrate lion with a human head—in front of the chest with a divine image, perhaps of Harmachis or Khepra. When later the monument was largely buried, Thutmosis IV had it cleared for the first time. On the stela celebrating this fact we find already the mixing of the meaning of the image of the Sphinx itself with the divine image in front of his chest. Perhaps it was then that the braided divine beard was added to the image. The Sphinx must have been partially freed from the sand in the Nineteenth Dynasty.

In a later time, the Sphinx was surrounded by a high brick wall in order to protect him from the drifting sand. \*16 From the east, a large staircase  $^{\dagger 17}$  led down to the small chapel in front of the divine image in front of the chest.

All these means of protection have not helped a great deal. In this century one has had to dig him out again repeatedly, last in 1883, and actually it would be necessary again today.

# **SPHINX**

JAMES BURTON (1822)

Taken from Burton's original unpublished manuscript in the British Library: MS. Add. 25,619, f. 32: [Note: The spaces marked by ellipses below are words written in the manuscript in Arabic script, which I have not transcribed.]

# **Sphinx**

The Sphinx is still called Aboo l'hol, a name by which it was known among the natives 650 years ago, and would seem to strengthen the etymology chosen by M. [Louis] Langlès for the word Belheet . . . or Belhoobeh . . . or Belhooyeh . . . which Makreesy [the historian Taqiyyu 'l-Din al-Maqrizi (1364–1442)] and Syotty [the historian Jalalu 'l-Din al-Suyuti (1445–1505), who wrote a history of Old and New Cairo among other works] give as the *true* one and which it seems according to M. [Silvestre] de Sacy is written thus in different copies and apparently also Belhoot, . . . according to M. Langlès, which he selects and says is compounded of the words . . . eye and . . . terror. The Arab name seems to be a translation of the Egyptian.

The countenance has yet the traces though faint of the red colour with which it was formerly covered, and which 6 or 7 centuries back, was coated with a varnish which then had all the brilliancy of freshness. The colour should certainly never be called *yellow*.

[He then quotes book 1, chapter 4, of Abdallatif about the Sphinx, a passage that we have already printed.]

[He then quotes Denon on the Sphinx, a passage we have already printed, and makes some comments on Denon's artistic remarks, which we omit.]

The statue was mutilated by a bigoted enthusiast [old-fashioned word for a fanatic], Sheckh [Sheikh] Mohammed, about year of the Hegira—? [Burton left a blank for the date.] It was probably when the nose was thus broken that the Asp [uraeus] and head dress were removed. There is little doubt that it carried these ornaments, from the hole now remaining in the top of the head, which the natives have at some time or other enlarged, in the hopes of finding in the interior some hidden treasure. The head however is solid stone, and they soon found their labour useless. I think I remember Mr. [Henry] Salt having told me, that he found in excavating the temple between its paws, part of an asp in bronze. This will have been that placed over the forehead.

The rump was repaired with Mapara [?] stone probably by the Kornans [??]—their repairs were

destroyed again by the late Defterdar in order to serve as building materials for one of his palaces.

Moorad Bey [Murad Bey, died 1801; see his portrait in figure 2.8 on page 92] first uncovered the Sphinx but found nothing—he did not dig deep. The French then did it, and were equally unsuccessful. [Captain J.-B.] Caviglia finally succeeded, and the accompanying notice of the work is copied from the [here the text breaks off].

[The *verso* side of this manuscript leaf has Burton's copy of Henry Salt's plan of the paws and altar of the Sphinx, with identifying letters and specific descriptions. No succeeding leaf has been bound into this manuscript volume, and the subsequent leaves by Burton change subject.]

# A DESCRIPTION OF GIAMBATTISTA CAVIGLIA'S EXCAVATION OF THE SPHINX

Translated by Stefano Greco, with notes by Robert Temple

Privately published by his friend Annibale Brandi in 1823, from what is believed to be the only surviving copy.

A.B. [Annibale Brandi] *Compendious Description of the Pyramids of Giza in Egypt* (Livorno: Stamperia della Fenice, 1823).

[The final portion of this booklet dealing with the Sphinx is given here.]

Also important are the discoveries made when excavating around the Andro-Sphinx, and concerning the opening of various tombs located in the vicinity of the pyramids, as we will see in the continuation of these memories of mine. The short time that I was at the pyramids and my poor talent don't allow me to give a very exact description. However, assisted by cultivated people's advice, I continue as much as I can to describe what Mr. Caviglia accomplished.

This same Caviglia, after examining the Great Pyramid of Giza and discovering the continuation of the [descending] passage to the length of 280 feet further than was known, with a room at its end [now called "the Subterranean Chamber"], the link between that passage and the well shaft, and the small room of dark granite at the left corner of the tunnel, after cleaning the chambers of rocks and earth, and taking note of the fact that he didn't have any other clues to find new chambers, left the Great Pyramid to look for other antiquities in the vicinity. And these initiatives of his, to say the least, were not fruitless.

In fact, he commenced two separate works at the same time. One was clearing the sand from the body of the Sphinx, and the other was to examine a tomb close to the Great Pyramid. In this he found a statue of stone and various busts, and it is remarkable that in the corridor of the entrance there are some apertures, from which one can see the internal rooms where there were the mummies and their statues, and from these apertures probably the relatives of the deceased could observe the mummies that they were visiting, from time to time.

The Sphinx, which is the custodian of the sacred valley, should rather be called "Andro-Sphinx," i.e., the body of a lion with a human head, which was in fact the Theban Sphinx [he is referring to the Sphinx of Greek mythology, which was near Greek Thebes; he is not referring to Thebes in Egypt], with the beard and with the serpent [uraeus] on its forehead. The head, with an opening in its skull, which is about 7 feet deep, was cleared along with a part of its body to a depth of 30 feet. Caviglia then cleared the rest all the way to the base on the side of the face and from another side [the north side], which is 75 feet high.

The body of this colossus, in order to counteract the rough aspect (because of its delicate condition) of the calcareous rock of which it was sculpted, was embellished with hieroglyphs, which were similar to the ones of the Egyptian doctrines, and it was painted red also on the beard. The red color was sacred to the Egyptians. On the surface of its base they found the head of the serpent [uraeus], even though the rest of it was remaining on the forehead. At the end of the beard there are depicted two persons who are making offerings. Beneath the beard, at the distance of 8 feet, there is a small temple 12 feet tall, 8 feet wide, and 7 feet long.

The innermost wall of this [in front of the Sphinx's chest; he is referring to what we now call the Dream Stela, shown in figures 2.9, 3.3, 3.5, 3.7, 3.8, and 4.19] is a big tablet of red granite, completely full of hieroglyphs very well executed. [The bottom half of the inscription seen by Brandi has now vanished.] In the upper part of this there is a winged snake; a row of hieroglyphs divides the table in the center. From one side and the other inside two temples, there are two Theban Sphinxes to which two persons are making some offerings. The one on the left is offering a vase, and the one on the right side seems to have a hand in the fire, and with his other hand he seems to be pouring some liquid for perfumes. Both have triangular aprons [triangular aprons were worn by the pharaohs, and the "two persons" are two different images of Pharaoh Thothmes IV]; in the first, two serpents form a stair of seven steps, and in the second one the same serpent forms five steps; in the rest of the tablet there are other hieroglyphs and in the bottom part there are two crosses, not of the usual form. [This suggests that the Dream Stela inscription was intact at the time Caviglia excavated it, and that the loss of the bottom half of its inscription was due to damage inflicted on the stela after his sudden departure from Egypt because of a serious case of sunstroke, and that this damage to the lower half of the stela was intentional.]

The two sides [of the temple area] are of limestone and are also full of hieroglyphs. If facing outward from the Andro-Sphinx toward the paws, the scene is one of a normal wall guarded by a lion 2 feet long and made of white marble, about 25 feet away. But if facing the Andro-Sphinx, one can see another wall, 6 feet tall, with a window in the middle, located at the entrance of the small temple. In front of this window there is a base with a small granite column, which covers the hole of the window, and it seems put there specifically to block the view inside the small temple. On this wall there are another lion and a bird, representing the Egyptian Minerva, with some heads of statues. At the end of the paws, they also found a poem referring to the Andro-Sphinx, whose Egyptian mysteries are carved in Greek. [This is the poem by Arrian, inscribed on the middle toe of the left paw, now covered with "restoration blocks," which has been discussed in chapter 6, pages 316–23.] On other stones, also in Greek, there are some dedications to the same Sphinx.

The discovery of this table and of its hieroglyphs has deeply touched the fantasy of the superstitious Egyptian women of the near villages, who come numerous times to touch it and to take some pieces of it, believing it could help their fecundity, even though the Egyptians are already helped very much by the god of the orchards. [Evidently, the bottom half of the inscription of the Dream Stela was destroyed in this way, as it was intact when Caviglia excavated it, but not for long. I do not know what the god of the orchards refers to, but perhaps it is some local fetish image.]

Caviglia descended to an underground tomb, and found a large chamber containing an impressive sarcophagus of granite with its cover, in very good condition. [This is apparently the so-called Osiris Shaft beneath the Causeway of Chephren. Caviglia was the first European to discover it, as James Burton also records in his manuscript record.] He opened another tomb and he found a corridor with some hieroglyphs referring to the arts but mainly to agriculture, which was source of the richness of the nation, with the instrument that is shaped like alpha, which the Greeks have taken as the first element of their

alphabet. In another subterranean tomb, he found four corridors. In the first, there still are some hieroglyphs referring to the arts and sciences. The second one is full of the same hieroglyphs, and some sea fights are visible. From here to the left, one can enter the third corridor, which is entirely smooth, and at the right hand, the fourth corridor is also decorated with the same hieroglyphs, on the internal wall of which there is a niche in which there probably was a statue, because from both sides of it there are some characters presenting various offerings. On the right side of this corridor there are two more openings, which may lead to other corridors and rooms.

He opened many more tombs, in which he found other rooms, some of them with hieroglyphs; but since they had to enter the greater part of these by descending the shafts, they did not find much, because there was no way to breathe for those who entered.

Caviglia entered and opened a small pyramid, the one in front of the Great Pyramid, on the east side, and there he found rooms and passages that are more comfortable than the ones of the Great Pyramid. After excavating a lot in this one, and after searching in the subterranean passages, he found the space of a lodge which resembles the antrums of Minerva; this space consists of four small caverns, excavated in the calcareous rock. The upper part of the door jamb of the first cavern is the biggest one and has the shape of a cylinder, where there are two eyes sculpted, one being big and the other small with a square on the right and a rectangle on the left; I don't understand what they refer to. In the left wall there are quite-well-preserved hieroglyphs, and above them all a seated statue, in front of which a bended figure which seems to be playing a harp, and further there is a scribe, maybe noting the names of the ones who enter the boat of Charon, which is very well decorated, and they leave to cross the [River] Styx. [This is an attempt to explain the Egyptian pictures in terms of Greek myths.]

In this cave there is the passage to another superior and smaller one, whose door jamb is also cylindrical but with no sculptures. This cave is linked to another one, from which it is possible to enter a small room. From the main cavern it is possible to descend to a deep subway, where probably there was what we would call "the Terrible Hall of Judgement." There is nothing else which is remarkable about these two pyramids, which are in the middle of a large, sandy valley. The small pyramid [of Mycerinus] is not accessible, because so far, nobody has ever succeeded in removing all the stones that surround it, and it seems, as they say, that it is not worthwhile to go to the trouble of trying to find its entrance. The other five pyramids are very far from these, and they are in northern Egypt, but they are not as beautiful as the ones of Giza. The perpendicular height of this Great Pyramid is 462 feet tall, i.e., 70 tese, and its sides are 660 feet long, i.e., 110 tese.

[Note: *tese* is plural for *tesa*, which was an Italian unit of linear measurement at this time, sometimes also used as a volumetric unit. The unit was borrowed from the French during the Later Middle Ages, the Middle French name being *toise*, from the Late Latin word *tesa*, from the earlier Latin *tensa*, meaning "outstretched arms," via Mediaeval Latin *tensa*, *teisa* meaning "expanse, extent," and also from Latin *te(n) sa/tensus/tendere*, "to stretch," hence "the stretch, reach, extent, or size of (a road)." The value of this unit varied enormously in nineteenth-century Italy between the value of 1.414 meters at Novara and the value of 2.242 meters at Bardonecchia. (As a volumetric unit, it varied similarly, and was approximately 2 cubic meters.) Brandi is using *tese* in a loose sense, not a precise sense, to mean in the first instance 6.6 feet and in the second instance 6 feet; however, the feet are apparently not English feet but French feet of the nineteenth century, *piedi*, or *piedi* "del Re." Brandi's use of this now obsolete unit of measurement, the *tesa*, and the fact that he contradicts himself in terms of its value in the two instances he gives, means that he is only being approximate. Hence we do not really need to concern ourselves with his mention of *tese*, but just in case there are those who might worry, I have given this survey of the issue,

## SCIENTIFIC VISUAL DOCUMENTATION OF THE SPHINX

The following images—"Sphinx Figures"—were all drawn by Mark Lehner or under his supervision, on behalf of an international research project on the Sphinx, and are all from his lengthy report, "Documentation of the Sphinx," in *The First International Symposium on the Great Sphinx, Book of Proceedings*, Cairo, 1992. I have used Lehner's own figure numbering and include his explanatory captions, either in whole or in part, in quotation marks, keeping my own additional comments separate from his so that it is obvious that my opinions are my own and not his. He shares no responsibility for any of my views and, in fact, he holds contrary ones. The Cairo reports of 1992 are hard for people to obtain (I bought mine in Cairo), and I am pleased to give a wider circulation of these illustrations to the general public, as they deserve to be much more widely known than they are at present.

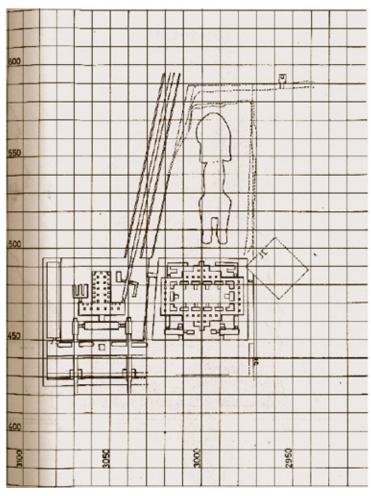

Figure 1. This figure is described by Lehner as "the local Sphinx grid of the ARCE Sphinx Project." (ARCE stands for the American Research Centre in Egypt, with which Lehner is affiliated, as he is an American.) This plan is incomplete for the Valley

Temple, some of whose internal features are omitted, though they are perhaps not relevant to a symposium on the Sphinx. I am puzzled by this grid showing the Sphinx facing the western wall of the Sphinx Temple directly. I know that all existing plans do show this, including those of the excavator Herbert Ricke (see figure 6.52), and the evidence of the naked eye certainly suggests the same at ground level. However, I would call your attention to the aerial view of the Sphinx seen in figure 4.2, which appears to offer incontrovertible evidence that the Sphinx is really facing the North Trench, just north of the Sphinx Temple, rather than facing the western wall directly. I don't know whether some bizarre optical illusion is at work here. I am inclined to believe that the optical illusion is the one at ground level and that the aerial photo is the more reliable evidence. I certainly never noticed anything odd at ground level, and so I am not accusing Egyptologists of being dolts, I am just pointing out that we may all be wrong about this. I call for a new and ultra-precise survey to establish the truth about this enigma. Is the Sphinx facing the North Trench, as suggested by the aerial photo, or not? If it is, then this plan and all the other existing plans are in error. There is no use in our burying our heads in the sands of Giza; we must find out the truth about this point, as it may have importance. We absolutely have to know the exact truth about the orientation of the Sphinx.

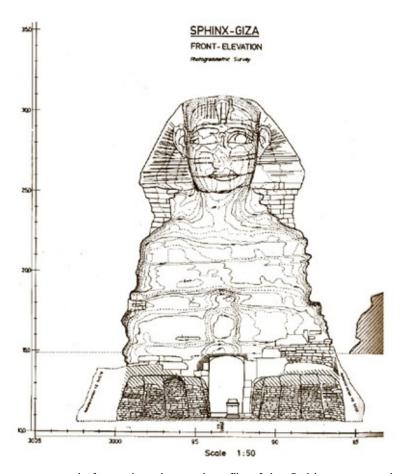

Figure 2. Lehner says of it: "Photogrammetric front elevation and profile of the Sphinx; contour interval is 25 cm. Original drawing is scale 1:50." I think we should note that the altar, though spaced evenly between the paws, is not centered with the Dream Stela, or the sphinx axis. This suggests to me that the Sphinx really is skewed to its left (to the right in this drawing) and is actually facing the North Trench. However, I do not insist upon anything, as we need a proper survey before anyone can be certain of anything regarding this matter.

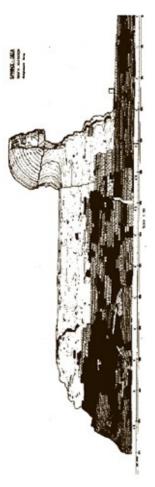

Figure 3. Lehner says: "Photogrammetric south elevation of the Sphinx. Ancient masonry that showed as of September 1979 is shaded. Original drawing is scale 1:50." The tiny head is clearly seen here to be out of proportion with the vast body.

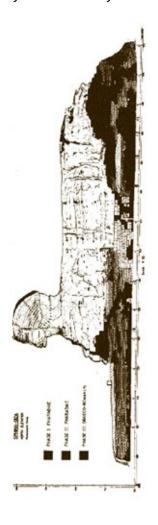

Figure 4. Lehner says: "Photogrammetric north elevation of the Sphinx. Ancient masonry that showed as of September 1979 is shaded. Original drawing is scale 1:50." The entrance blocked up by Baraize in 1926 at the base, just behind the Sphinx's head, is shown here as modern masonry.

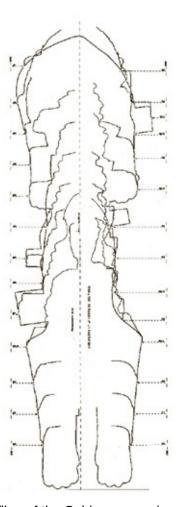

Figure 5. Lehner says: "Photogrammmetric profiles of the Sphinx, approximately every 5 m, laid onto the base outline of the Sphinx. Original drawing is scale 1:50." This may look uninteresting, but in fact it is an extremely useful study of the successive profiles, and it has the merit of showing particularly clearly the four strange stone "boxes," two on the north side and two on the south side, that protrude from the Sphinx at the base. No one really knows what they are, although some or all may well have been statue bases. (There is some surviving evidence suggestive of the possibility that a statue of Osiris was erected on one of them.) Of course, some of these bizarre "boxes" may be connected with entries to the interior of the Sphinx. We don't know how old they are, but it is doubtful that any is older than the New Kingdom, and some may even be Roman. They have never been sufficiently studied.

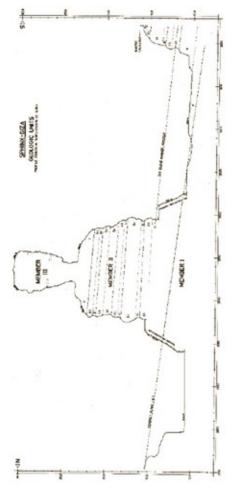

Figure 6. Lehner says: "Profile of the Sphinx face, chest, and sides of the Sphinx ditch with geological units indicated. Original drawing is scale 1:50." The purpose of this drawing is to show the successive geological strata of the limestone from which the Sphinx is carved, all of which are slanting as shown. "Member III," of which the head is carved, is a stronger limestone layer than is "Member II," of which the chest is carved.

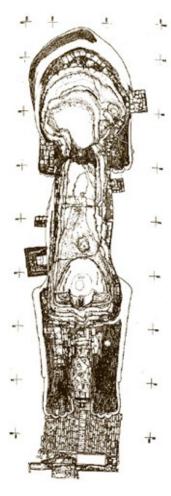

Figure 7. Lehner writes: "Contour map of the Sphinx natural rock core body; contour interval is 10 cm. Original drawing is scale 1:50." This useful plan shows that the altar area between the legs of the Sphinx and its extension eastward are skewed to the south. This may really mean that it is the Sphinx itself that is skewed to the north. Only a more careful survey can tell us. This plan shows how the four strange boxes are made of small stones.

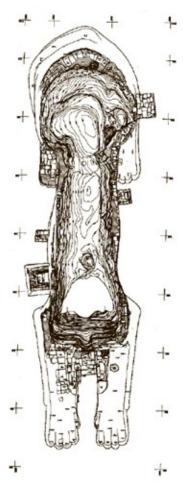

Figure 8 (wrongly described in Lehner's text captions as figure 9). Lehner says: "Form-line master plan of the Sphinx. Original drawing is scale 1:50." (Figures 8 and 9 have their captions mixed up in Lehner's text as published, but that is rectified here.)

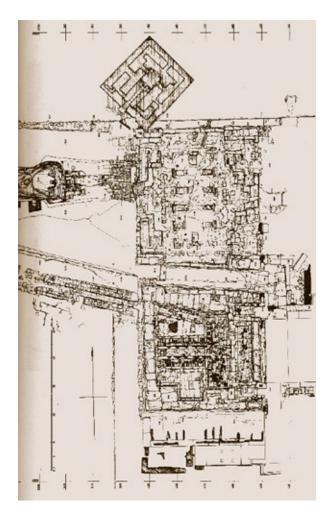

Figure 9 (wrongly described in Lehner's text captions as figure 8). Lehner says: "Detailed map of the temples in front of the Sphinx; Khafre [Chephren] Valley Temple, left; Sphinx Temple, right; Amenhotep II Temple, upper right. Original scale 1:100." The small Amenhotep Temple at far right (see figures 7.3 to 7.5 on pages 327 and 328) dates from the New Kingdom and was built when the existence of the Sphinx Temple beside it was unknown and covered in a mountain of sand. The corridor between the two major temples is well shown here and is discussed at length.

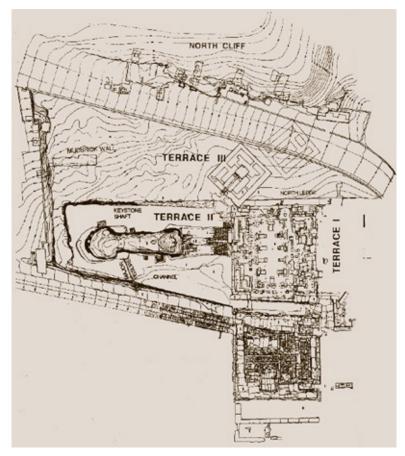

Figure 10. Lehner writes: "Map of Sphinx 'amphitheatre.' Contour interval is 50 cm. Original drawing is scale 1:200."

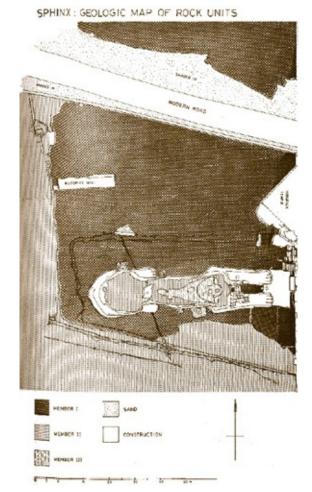

Figure 11. Lehner says: "Map of bedrock units: Member I (base), Member II (Sphinx body), and Member III (Sphinx head)." The diagonal crack going across the haunches in the underlying bedrock from northwest to southeast is well shown here, and it crosses the Sphinx at precisely the point where the huge blob of modern cement placed by Baraize in 1926 may be seen. The crack in the bedrock was probably caused by the shock associated with the intrusion of the shaft and construction of the chamber below.

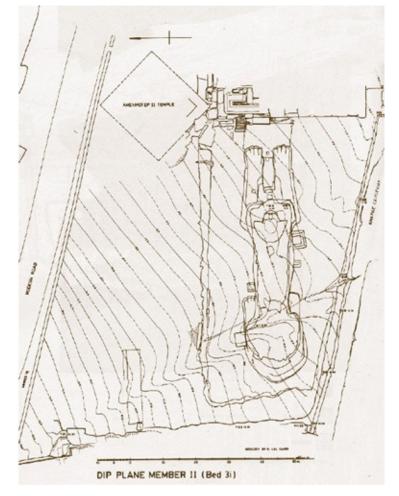

Figure 12. Lehner says: "Map of dip place of Member II through Sphinx 'amphitheatre'; contour interval is 50 cm."

# **FOOTNOTES**

- \*1. [The original French text says: Devant chacune des trois pyramides se voyent encore des vestiges de certains bastimens quarrez [obsolete form of the word carré], qui semblent avoir esté autant de Temples, & á la fin du pretendu Temple de la seconde pyramide est un trou, par lequel quelques-uns croyant qu'on descendoit de dedans le Temple pour aller dans l'Idole, qui est eloigné de quelques pas de ce trou.]
- \*2. [The original French text says: . . . il y auroit plus d'apparence de croire qu'on y entrast par le trou que i'ay dit estre dans le pretendu Temple de la second pyramide, ou plustost encor par un autre trou qui est á costé de cét Idole, & fort proche; ces deux trous sont fort estroits, & Presque tout bouchez de sable, c'est pourquoy nous n'y entrasmes point, ne sçachans mesme si nous n'y trouverions point quelques vipers ou autres bestes venimeuses; mais quand après avoir percé les rochers, on seroit venu dans cét Idole, par ou seroit sortie la voix de ce feint Oracle, puis qu'il n'y a point de trou á sa bouche, ny á son nez, ny á ses yeux, ny á ses oreilles?]
- \*3. [Wilde adds in a footnote: "The sand has again accumulated so much on the back of the sphinx, that it is easy to ride to the top."]
- \*4. The numbers given for the Cairo Collection are those of the new Inventory of the Collection, which is not yet published, but wherever possible, I have given the old numbers as well, to facilitate their consultation in the catalogs which are presently for sale. Wherever there are no old numbers available, then I have at least given the room numbers.
- \*5. For several of statues of named kings, the makeup stripes are not shown in relief. However, they must nevertheless not be counted for statistical purposes.
- <u>\*6.</u> For instance, the statue of Horemheb next to Amun at Turin and others. Also, already on the statues of Sebekhotep in Paris (de Rougé, *Notice des mon.*, Numbers 16/17, page 15 ff.).
- <u>†7.</u> For instance, the colossal bust of Ramesses II in London and others.
- \*8. We are always speaking only of the stripes on the upper part and the side part of the cloth. The regular pleating of those cloths falling over the chest are not considered here.
- <u>†9.</u> With 3 and 4, we have another indication of the criteria of the Middle Kingdom, namely the rounding of the front horizontal edge of the seat.
- <u>‡10.</u> See Golenischeff in *Recueil de Travaux* (1893), pages 131 ff.
- \*11. See Mariette in *Athenaeum Français* (1855), page 392.

- \*12. The beard, which [ John] Perring found ([Howard Vyse,] *Operations at Giza*, vol. 3, between pages 108 and 109), is one made out of ashlar afterward cemented onto it, probably in the New Kingdom. It is an added, braided divine beard which the Sphinx only received when he was changed from one of the kings into a god. Herr Sethe has pointed out to me that the Sphinx was viewed erroneously by the Egyptians as an image of Harmachis. Originally, every sphinx was only the depicted king shown as a lion.
- †13. The expression . . . [hieroglyphics] . . . (LD. III 68 Z. 7) could also mean: "The Sphinx with the Khepra," and also on the stela . . . [hieroglyphics] . . . (op. cit., Z. 11) "the sand is rising over me" probably refers only to the divine image in front of the chest, because the back and the head of the Sphinx were probably never covered with sand; however when it talks about . . . [hieroglyphics] . . . (op. cit., Z.8) "the shadow of this great god," one cannot really see a reference to a king even though it could be inferred according to the words, because one would expect to see the name of that king. So already they here thought of the Sphinx as a god.
- <u>**‡14.**</u> See the figure LD. III, 68.
- §15. See the stela of Ramesses II. ([ John] Perring and [Howard] Vyse, op. cit., vol. 3, page 117).
- \*16. The east side and the southeast corner of it are today still visible, the west side is given by Mariette (*Mastabas*, page 551). This particular wall could already have existed in the New Kingdom, at least the representation of the Sphinx on the stela of Thutmosis IV (LD. III, 68), where the Sphinx figure is shown to be apparently lying on a building, according to the Egyptian laws of perspective, can also be interpreted in such a way that the Sphinx figure is inside a building open at the top, meaning this particular circular brick wall.
- <u>†17.</u> See [ John] Perring and [Howard] Vyse, *op. cit.*, vol. 3, pages 110 and 113.
- **‡18.** The fact that Herodotus never mentioned the Sphinx, however, is not so much because of it being covered by sand, because the head has never been covered completely, but the reason of its rather hidden location. You can only see the Sphinx from very few vantage points in the necropolis—actually, only from the very closest surrounding.

#### **Chapter 3. An Amazing Survival**

- 1. Anonymous, "Antiquities of Egypt," Quarterly Review 19, no. 38 (July 1818): 391–424. The full title heading of the article is: "Observations Relating to Some of the Antiquities of Egypt, from the Papers of the Late Mr. Davison. Published in [Robert] Walpole's Memoirs." It is important to realize that it is Robert Walpole, not Horace Walpole, whose memoirs are referred to here; Horace Walpole was the more famous author of *Memoirs*, and initially I was confused by this. The Mr. Davison referred to is the discoverer of "Davison's Chamber" in the Great Pyramid. The account about Caviglia's excavations at the Sphinx has nothing whatsoever to do with either Davison or Walpole, and if one were not told, one would have not the slightest idea that they occur in an article purporting to be a review of quite another book in which the Sphinx is not even mentioned. This was the eccentric way in which the Quarterly Review occasionally acted as a forum for material only vaguely related to the subject of a "review." The reference for the Walpole/Davison material is: Robert Walpole, Memoirs Relating to European and Asiatic Turkey, Edited from Manuscript Journals (London, 1817): pp. xx-xxi and 345-82. The material published by Walpole consisted of extracts from the manuscript diaries of Nathaniel Davison and letters found among his papers, which were made available to Walpole by Davison's widow, who lived at that time at Alnwick, Northumberland, and by Davison's nephew, Dr. Yelloly, of Finsbury Square, London. Davison died in 1809. I am not aware whether the manuscripts of Davison still exist, but I have never come across them. Perhaps somebody should make a search for them. Davison did very important work at the Great Pyramid and elsewhere, and his papers would be of the greatest importance to Egyptology. He counted and measured all the tiers of stone composing the Great Pyramid, and Davison's Chamber above the King's Chamber in the Great Pyramid is named after him, as he was its discoverer.
- 2. Ibid., 416.
- 3. Anonymous, "Account of the Recent Discoveries in Egypt Respecting the Sphinx and the Great Pyramid," *The Edinburgh Philosophical Journal* 1 (June to October 1819): 88–96 (the quotation is from p. 95).
- 4. Quarterly Review, "Antiquities of Egypt," 410.
- 5. Selim Hassan, *The Great Sphinx and Its Secrets: Historical Studies in the Light of Recent Excavations* (Cairo: Government Press, 1953), 92–93. This large book is not the same as Hassan's earlier, smaller, and much briefer book *The Sphinx: Its History in the Light of Recent Excavations* (Cairo: Government Press, 1949). In notes I shall call the former *Great Sphinx* and the latter *Sphinx*. A much better edition of *Sphinx* appeared in French. It was in a larger format with much clearer illustrations. It is Selim Hassan, *Le Sphinx: Son histoire a la lumière des fouilles récente*, Cairo, 1951. We shall call this *Le Sphinx*.
- <u>6.</u> Robert Temple, *The Crystal Sun: Rediscovering a Lost Technology of the Ancient World* (London: Century, 2000).
- 7. Hassan, *Sphinx*, 30.

- 8. Ibid., 25.
- 9. Herbert Ricke, ed. and contributor, *Beiträge zur Ägyptischen Bauforschung und Altertumskunde*, Heft [vol.] 10, Wiesbaden, 1970. The illustration is Plan 4, though it is unnumbered. It is unclear whether it is meant to be part of Ricke's portion of this volume, "Der Harmachistempel des Chefren in Giseh," or that written by Siegfried Schott, "Ägyptische Quellen zum Plan des Sphinxtempels." (I should add by way of explanation that although Schott calls the Sphinx Temple the Sphinx Temple, Ricke calls it the Harmachis Temple. These two names are used in the same volume!)
- 10. Ludwig Borchardt, "Über das Alter des Sphinx bei Giseh" ("Concerning the Age of the Sphinx at Giza"), in *Sitzungsberichte der Preussischen Akademie der Wissenschaften*, vol. 8, Berlin, July 1897.
- <u>11.</u> Hassan, *Great Sphinx*, 158–60.

# Chapter 4. The Face of the Sphinx

- 77. "Observations relating to some of the Antiquities of Egypt, from the papers of the late Mr. Davison," *Quarterly Review* XIX (April and December, 1818); London, 1819, pp. 391–424. (The reason for two dates with this reference is that the issues of the periodical were for 1818, but the bound edition of them came out in 1819 in volume form.) The original Greek inscription, entirely in capital letters, is faithfully reproduced on p. 411, and the transliteration into lowercase Greek, the Latin translation, and the English translation are all on p. 412. (These were all done by "Dr. Young.")
- 78. Simplicius, *Epictetus His Morals*, *with Simplicius His Comment*, *Made into English from the Greek* by George Stanhope, London, 1694. I bought this book so long ago, from Quaritch's

Catalogue 927, which I see from the price written inside and the catalog entry that I clipped and inserted in the book, that it only cost me £10 (although that was a lot then). My copy contains the hand corrections by the translator himself and seems to have been his own personal copy. The leather spine is plain, as he had no need to be told what it was when it was sitting on the shelf beside him. From the nature of Stanhope's corrections, I can see that he must have been irritated by some of the printer's errors, such as mistaking "which" for "when." But in those days, printers did have to struggle to read the handwriting of authors, and that was the cause of many typographical errors. Today, things are different, because so many people under the age of thirty lack the ability to spell correctly due to the collapse in effective teaching methods as a result of the intrusion of crazy political ideas into the educational field, combined with the decline of the print medium in this "I.T. Age," so that even if things are printed out perfectly clearly by the computer, many young people can no longer "read" them, as they simply do not "see" spelling anymore and have no way way of retaining it in their minds, which have not been trained to do so. Also, few young people read enough anymore for standardization of spelling to enter into the memory. And then there are the corrupting influences of abbreviated "texting" by thumb-messaging over handheld devices, so that spelling ends up being dictated by the movement capabilities of the human thumb, in disregard of the obvious fact that the human thumb is of an inferior status to the human mind, which should be making these decisions. In the twenty-first century, our society is thus reverting to spelling by sound rather than by convention established by the print medium, and has in that sense gone back to the lack of precise spelling characteristic of the seventeenth century. Who says there is such a thing as "cultural progress"? "Decline," on the other hand, requires no proof of its existence.

- 80. See Robert Temple, *Oracles of the Dead* (Rochester, Vt.: Inner Traditions, 2004), for an account of my visit to an underground shrine of Persephone, goddess of the underworld. (This book was entitled *Netherworld* when it was first published in Britain in 2002.) See also the fifty-two-minute television documentary film that I wrote, produced, and presented, entitled *Descent into Hell*, which is shown from time to time on the National Geographic Channel. In one scene, I leave a traditional offering of a bough of mistletoe (brought from England) for Persephone in the very same niche where the fictional hero Aeneas is described as doing so in the *Aeneid* of Virgil. (Virgil was personally familiar with this underground sanctuary known as the Oracle of the Dead, at Baia.)
- <u>81.</u> Hassan, *Great Sphinx*, 123. Selim Hassan chose to publish this modern prose version rather than to quote the even more old-fashioned verse translation that was published in 1818.

# Chapter 7. The Sphinx and the Giza Plan

1. This is a subject that I discussed in my earlier book *Open to Suggestion: The Uses and Abuses of Hypnosis* (England: Aquarian Press, 1989), 49–50, in the context of the evidence I presented

about how people can still hear when they are in a state of coma or under an anesthetic on the operating table, a phenomenon known as "surgical memory." The sense of hearing is the last to go when you die, and the Tibetans somehow knew this, and realized that shouting into the ears of someone who appears to be dead is not necessarily pointless at all, but may actually be helpful.

- 22. This strange expression may conceivably be a reference to a wall or slab of basalt, which, being black, is the color of charcoal. That is just my guess. However, no Egyptologist has ever discovered the name by which basalt was known to the ancient Egyptians. This strange fact is recorded by the leading expert on ancient Egyptian names for stones and minerals, J. R. Harris. He says of basalt: "No name is known." (From Harris, J. R., *Lexicographical Studies in Ancient Egyptian Minerals*, Akademie-Verlag, Berlin, 1961, p. 94.) Basalt largely ceased to be used after the Old Kingdom, but its occurrence in both building and statuary prior to 2200 BC was substantial. The fact that we do not know the ancient name for basalt means that references to it have probably been misunderstood in the texts, where it has doubtless been mentioned but not recognized. Hence, a reference to a "charcoal wall" might, for all we know, actually mean "a basalt wall," or a common word meaning "black substance" might have been used as a general term for both charcoal and basalt. We need always to keep in mind our ignorance when dealing with matters concerning basalt in ancient Egypt. See figure 4 for an example in the Valley Temple, which is at Rostau.

Griffiths adds a curious detail that at the Island of Philae, the *redju* of Osiris that created the Nile was regarding as coming from his left leg. This is doubtless an esoteric reference with an important meaning. If Osiris was regarding as rising in the east at dawn (see discussion of this later in this chapter), then his left leg would be his southern leg. The god Ptah was conventionally described as being "south of his Wall." These references to the cardinal directions are always significant. (See also the later discussion of the shadow on the south face of the Great Pyramid.)

# About the Author

Robert Temple is visiting professor of the history and philosophy of science at Tsinghua University in Beijing; fellow of the Royal Astronomical Society; member of the Egypt Exploration Society, Royal Historical Society, Institute of Classical Studies, and the Society for the Promotion of Hellenic Studies; and visiting research fellow of the University of the Aegean in Greece. He is the author of 12 books, including *The Sphinx Mystery, The Sirius Mystery, Oracles of the Dead, and The Genius of China*. He wrote, produced, and presented the documentary film *Descent into Hell*, based upon his book, *Oracles of the Dead*, for National Geographic Channel. His translation of the Epic of Gilgamesh was staged at the Royal National Theatre in London in 1993. He resides in England with his wife, Olivia. They are joint translators of *Aesop: The Complete Fables*.

Olivia and her husband Robert translated *Aesop: The Complete Fables*. They live in England.

# About Inner Traditions • Bear & Company

Founded in 1975, <u>Inner Traditions</u> is a leading publisher of books on indigenous cultures, perennial philosophy, visionary art, spiritual traditions of the East and West, sexuality, holistic health and healing, self-development, as well as recordings of ethnic music and accompaniments for meditation.

In July 2000, Bear & Company joined with Inner Traditions and moved from Santa Fe, New Mexico, where it was founded in 1980, to Rochester, Vermont. Together Inner Traditions • Bear & Company have eleven imprints: Inner Traditions, Bear & Company, Healing Arts Press, Destiny Books, Park Street Press, Bindu Books, Bear Cub Books, Destiny Recordings, Destiny Audio Editions, Inner Traditions en Español, and Inner Traditions India.

For more information or to browse through our more than one thousand titles in print, visit <a href="https://www.InnerTraditions.com">www.InnerTraditions.com</a>.

- 18. Robes, 89

Notes on Consecration, 91 Recommended Reading, 91 Dedicated to Israel Regardie, who has shed Light on the Path, for all of us.

### Acknowledgments

Thanks are due to Timothy Miles, whose advice has greatly influenced the form and content of this book. Moreover, a large measure of appreciation is owed to Donald Weiser and to my editor, Gale Courey, both of whose kind support, encouragement, and always wise criticism, makes authorship a pleasant task.

# 1 / Preface

This is a practical book. It is intended for those who feel a natural inclination toward ritual, and who are willing to expend the special effort required to produce a full set of magical instruments and a personal Temple. The very act of developing the Wands, Cup, Tablets, etc., is a devotional one which may lead the student to an inner mainstream. It is a form of sacrifice.

The instruments and Temple described herein are those specified by the Hermetic Order of the Golden Dawn. They are, however, based on principles which have not varied over the centuries. Particular to the Golden Dawn is its emphasis on the four Elements, symbolized by the Wand, Cup, Dagger and Pentacle. These instruments represent the component parts of the personality, as is also represented by the five-pointed star of Pentagram. In this figure the fifth point is that of Spirit.

Those who ascribe to the methods taught by Aleister Crowley will experience few difficulties in adapting the materials in this book to his ritual practices, all of which grew from the practices of the Order of the Golden Dawn. Crowley was not very explicit, in his writings, about these instruments. In his Equinox, Magick in Theory and Practice and Magick Without Tears he discussed the subject without mention of the inscriptions to be placed on the instruments. But for those who possess the practical keys of the Golden Dawn, Crowley's work provides a dimension of insight which is unique.

His most useful advice is given in a letter to a friend, published in Magick Without Tears:

Let us consider what one can do with an ordinary house. . .

First of all, it is of immense advantage to have a room specially consecrated to the Work, never used for any other purpose, and never entered by any person other than yourself, unless it were another Initiate, either for inspection or in case you were working together.

The aura accumulates with the regularity and frequency of Use.

The first point is the Banishing: Everything is to be removed from the room which is not absolutely necessary to the Work. . .The walls should be 'self-coloured,' a neutral tint-green, grey or blue grey? — and entirely bare, unless you put up in the proper quarters, the proper designs, such as the 'Watch Towers.' . . . Next, your Circle. The floor ought to be 'Earth' green; but white will serve, or black (A Masonic carpet is not at all bad.) . . .The Altar must fit exactly the square of Tiphareth; it is best made as a cupboard; of oak or acacia, by preference. It can then be used to hold reserves of incense and other requisites.

Note that the height of the Altar has to suit your convenience. It is consequently in direct relation with your own stature; in proportion it is a double cube. This then determines the size of your circle; in fact the entire apparatus and furniture is a geometrical function of yourself. . . .Next, the Lamp. This may be of silver, or silver-gilt (to represent the Path of Gimel) and is to be hung from the ceiling exactly above the centre of the Altar. There are plenty of old church lamps which serve very well. The light is to be from a wick in a floating cork in a glass of olive oil. . . It is really desirable to make this as near the 'ever burning Lamp of the Rosicrucians' as possible; it is *not* a drawback that this implies frequent attention.

Now for the Weapons!

The Wand. Let this be simple, straight and slim! Have you an Almond or Witch Hazel in your garden . . .? If so, cut (with the magic knife. . .) a bough, as nearly straight as possible, about two feet long. Peel it, rub it constantly with Oil of Abramelin. . .and keep wrapped in scarlet silk. Constantly I wrote, and meant it; rub it, when saying your mantra, to the rhythm of that same.

. . . The Cup. There are plenty of chalices to be bought. It should be of silver. . .

The Sword. The ideal form is that shown in the Ace of Swords in the Tarot. At all events, let the blade be straight, and the hilt a simple cross.

. . . The Disk. This ought to be of pure gold, with your own Pantacle, designed by yourself after prolonged study, graved thereupon. While getting ready for this any plain circle of gold will serve your turn. Quite flat, of course. If you want a good simple design to go on *interim*, try the Rosy Cross or the Unicursal Hexagram.

So much for the Weapons! Now, as your personal accourrements, Robe, Lamen, Sandals and the like, The Book of the Law has most thoughtfully simplified matters for us. 'I charge you earnestly to come before me in a simple robe, and covered with a rich head-dress.' (AL, I:61) The Robe may well be in the form of a Tau Cross . . . The best head-dress is the Nemyss . . . you can easily make one yourself out of silk; broad black and white stripes is a pleasing design. Avoid 'artistic' complexities.

I feel moved to add a line of caution and encouragement . . .

Just as soon as you start seriously to prepare a place for magical Work, the world goes more cockeyed than it is already. Don't be surprised if you find that six weeks intense shopping all over London fails to provide you with some simple requisite that normally you could buy in ten minutes. Perhaps your fires simply refuse to burn, even when liberally dosed with petrol and phosphorus, with a handful of Chlorate of Potash thrown in

just to show there is no ill feeling! When you have almost decided that you had better make up your mind to do without something that seems really quite unobtainable—say, a sixty caret diamond which would look so well on the head-dress—a perfect stranger comes along and makes you a present of one. Or, a long series of quite unreasonable obstacles or silly accidents interfere with your plans: or, the worst difficulty in your way is incomprehensibly removed by some extraordinary 'freak of chance.'

In a word, you seem to have strolled into a world where, well, it might be going too far to say that the Law of Cause and Effect is suspended; but at least the Law of Probability seems to be playing practical jokes on you.

This means that your manoeuvres have somehow attracted the notice of the Astral Plane: your new neighbours (May I call them?) are taking an interest in the lastest Tenderfoot, some to welcome, they do all they can to help you to settle down, others indignant or apprehensive at this disturbance of routine. This is where your Banishings and Invocations come to the rescue. Of course, I am not here referring to the approach to Sanctuaries which of necessity are closely guarded, but merely to the recognition of a new-comer to that part of the world in general.

Of course all these miracles are very naughty of you; they mean that your magical power has sprung a few small leaks; at least, the water is oozing between some planks not sealed as Hermetically as they should be. But oh—and this is naughtier still—it is blessed, blessed comfort that they happen, that chance, coincidence, and all the rest will simply not explain it all away, that your new vision of life is not a dream, but part and parcel of Experience for evermore, as real as any other manifestation of Reality through sense such as is common to all men.

Crowley did not deviate from the Golden Dawn methods (in which he was instructed by Alan Bennett) until he had

thoroughly mastered them. These methods are both safe and sound, when followed to the letter, and are ideal for personal development. The manufacture of these instruments and Temple is an exceptionally strong way to approach the western esoteric Path. The reason is that the Golden Dawn, as opposed to most other systems, offers a totally structured 'course of studies.' Yet this is a method from which one may branch out freely once its principles have been understood.

While it is generally agreed that the most efficacious tools for ritual are those created by the student himself, not everyone is an artist or craftsman. Few today could follow the strict early directions stating that one must forge his own sword from solid steel! The important principle is that we do as much as we can, because the instruments become *charged* as they are made. The more effort expended, the more energy is attached to each piece.

Many of these materials, such as the Sword, Dagger and Cup, can be purchased ready to paint. One assumes true ownership of an instrument by painting it with the appropriate God Names and Sigils, and by its consecration. Those who lack time or skill are advised to commission their instruments from professional craftsmen, and then paint each piece as specified herein. We are required only to do our best, and are assured that the Gods will meet us half way.

One important point to consider is the extent to which these instruments are a means to an end. It is all too easy to become absorbed in the beauty and minutae of the tools, to the extent that they acquire false importance. A plow is of no intrinsic significance except as it facilitates the tilling of the soil from which new life will emerge. The Magical Instruments are important in that they, too, facilitate a process leading to new life. But they are not essential; they are helpful. As Crowley said: "All sense and faculties must share in the work, such at least is the dictum of Western Ceremonial Magic. And so we find the magician placing stone upon stone in the construction of his Temple. That is to say, placing pantacle upon pantacle, and safeguarding his one idea by means of swords, daggers, wands, rings, perfumes, suffumigations, robes, talismans, crowns, magic squares and astrological charts, and a thousand other symbols of things, ideas and states, all reflecting the one idea; so that he may build

up a mighty mound, and from it eventually leap over the great wall which stands before him as a partition between two worlds."

Unfortunately, some may believe that the construction of a Temple. and the traditional instruments of the magician will confer instant enlightenment and power of some sort. It may be supposed that this is a relatively painless way to effect entry into the Inner Worlds, which is not at all true. The Magical Path is as slow and arduous as the Meditational Path.

Western ritual is admittedly theatrical. There is, in fact, something very flambuoyant about the creation and use of the magical instruments. But this is as it should be. Ritual and its accoutrements offer a special focus of attention, drawing us inward. An easterner may sit silently on the ground and invoke the forces of nature with enviable simplicity. We, on the other hand, must contend with an energetic environment working against inner tranquility. Ritual helps us to transcend the weighty dynamism of our culture. As one assumes the goldedged white robe, feels the slight weight of the Rose-Cross Lamen around his neck, and begins to work with the tools of traditional esoteric science, there is a feeling that one stands between two worlds. It is as profound a feeling as that of a priest preparing for the Christian Eucharist. And, of course, that is the point: by preparing our instruments and Temple, we may, in a lesser way, ordain ourselves into the priesthood of the Great Work.

Ideally, one would belong to an Order, where the preparation of these materials is part of the initiation of Tiphareth. Yet far too many of today's so-called "Orders" (including some established by very great occultists of the past) are of suspect integrity. Suffice it to say that if one is intended to work with a truly enlightened group, it will find him. As the aphorism states: When the student is ready, the master appears.

Individual work is more difficult, but it is possible today thanks to publications of teachers in the Golden Dawn tradition such as Israel Regardie, Aleister Crowley, Dion Fortune, Paul Foster Case, Gareth Knight and W.E. Butler. Regardie's work, The Golden Dawn, is the primary source book for the system in which these instruments are used, and must be considered a life-

time study. Moreover, this present book may make little sense to those completely unfamiliar with Regardie's Golden Dawn.

## Minimal Requirements

There are many people who can afford neither the time nor the money for instrument construction, but who wish to pursue magic in some way. For those a 'stripped-down' version is possible, requiring little effort and virtually no craft skills. Such instruments are unlikely to have the vitality of a more sophisticated set, but they will allow ritual work to be performed.

The basic instruments are: The Wand of the Magician, The Fire Wand, The Water Cup, The Air Dagger and The Earth Pentacle.

### THE WAND OF THE MAGICIAN

This may be a piece of 3/4 inch dowel rod, approximately twelve inches long. It should be painted gold.

### THE FIRE WAND

This may be a piece of 1/2 or 3/4 inch dowel rod, ten inches long, painted bright red.

### THE WATER CUP

Any metal cup painted blue, or any blue glass cup would be appropriate.

### THE AIR DAGGER

Any knife or letter opener can be used, although a cross piece at the hilt is desirable. The knife is painted bright yellow.

### THE EARTH PENTACLE

This is a simple round wooden disc, approximately four inches in diameter, painted black. Hobby shops, hardware and lumber dealers often sell wooden circles of plywood.

The assembly and painting of these simple instruments requires about four hours, and little cost. The suggestion is made here to counter a common belief that magical tools are all but impossible to produce. In fact, one makes a commitment to

the system according to his own needs. One who is highly spiritually developed may not need to expend the effort to produce an elaborate set of instruments, although most people will find that pouring great energy into this work is invaluable in forming a link with the inner currents established by the Golden Dawn. There is, in this, something of being willing to sweep out the Temple before one is permitted to sacrifice at the altar.

A natural artist or craftsman may spend years producing a beautiful and highly sophisticated set of instruments which is personally appropriate. And again, these tools should be the best we can do. They become extensions of ourselves which are consecrated and, although they may be seen, must never be touched by another.

# Part I / The Instruments

. . 

.

• 

• 

• 

.

# 2 / The Lotus Wand

The wand is the primary tool of the magician in the Golden Dawn system, its consecration being a superb introduction to the rites of consecration in general. Some, however, express the opinion that the Lotus Wand is unnessessarily difficult to use. It is, admittedly, quite long, can never be inverted, and must be held by difficult sections according to the operation at hand. Despite such restrictions, many find it to be an exceptional instrument.

Since a wand symbolizes the Will it is a very personal tool, and ingenuity may be applied in its construction. Those who do find the Lotus Wand cumbersome may wish to prepare a second wand, of their own design, for more regular use.

A great deal has been written on the subject of wands, suggesting that to make one is a feat equaling the building of the pyramids. Contrary to ex cathedra pronouncements by certain occult writers, it is not necessary to cut a birch branch with a golden sickle, at two in the morning on the Sahara desert, when Pluto is conjunct Mercury. What is most important in the construction of any instrument is its consecration. And since the ability to consecrate is a measure of progress along the Path, a student spares no detail which may add to the energies contained in his instruments. It is for this reason that a simple set may be sufficient for the more spiritually advanced, who naturally confer power in consecration. Others must begin the process of consecration with the "sweat of their brows," building

energy into each piece as they work on it, and then intensifying and sealing that energy with a ritual of consecration.

One end of the Lotus Wand is white, symbolizing Pure Spirit, and the other end is black, symbolizing the Earth. They are the Light and Darkness between which are bands of color referring to the Signs of the Zodiac. The Planets are also implied here, since 'Planets live in Houses,' and one holds the band of the Zodiacal sign where a particular planet is resting, for an operation of that Planet.

Above all is a White Lotus flower. The Golden Dawn text states: "The 10 upper and inner Petals refer to the Purity of the Ten Sephiroth. The middle 8 refer to the counter-charged natural and spiritual forces of Air and Fire. The lowest and outer 8 refer to the powers of Earth and Water. The centre and amber portion refers to the Spiritual Sun, while the outer calyx of four orange sepals shows the action of the Sun upon the life of things by differentiation." It will be seen that there are twenty-six petals, which is the number of the Yod Heh Vau Heh. Yod (10) + Heh(5) + Vau(6) + Heh(5) = 26.

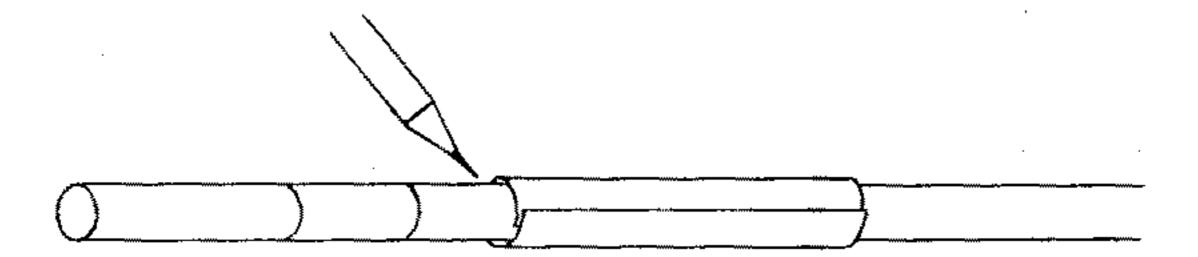

### Construction

The shaft of the wand should be 3/4 inch dowel rod, varying in possible length from 24 to 40 inches. In practice, the shorter length is best, since it is more easily manipulated and stored (Note that the instruments are stored inside the Altar).

- 1) Sand the rod lightly, rounding the end to be painted black.
- 2) Coat the rod with *gesso*, and again sand lightly. Gesso, a white acrylic medium, seals the wood and forms a base for finished painting. It is available in any art supply store.

This medium, which is water-based and fast drying, should be applied in two thin coats. Brushes must be washed immediately in soap and water, as a very hard and waterproof coat forms when gesso is completely dry.

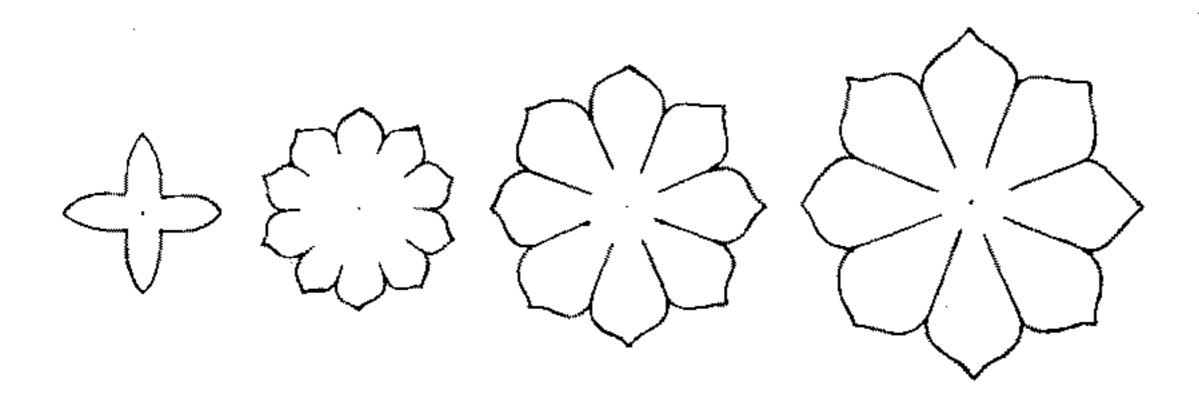

3) With a ruler and soft pencil, divide the rod into sections. The white end should be the longest, then the black, and finally twelve sections of equal size. Place small marks along the length of the rod. Then, with a rolled piece of heavy paper or cardboard acting as a circular straight-edge, inscribe lines around the rod:

4) Using artist's acrylic paint (those sold in tubes, not in jars), carefully fill in the colored bands as indicated on page 16. Work about half-way down the wand, and allow the colors to dry. Then invert the wand and complete the bands at the opposite end. A tall jar will provide support during this process.

Artist's acrylics are ideal for painting on wood. They are the brightest colors available, and produce the extraordinary "flashing" effect described in occult documents. A basic set of colors can be purchased, and mixed as needed. Like gesso, these are water-soluble, but harden quickly, and should not be allowed to dry on brushes. Acrylic paints should be washed from brushes with soap and warm water (hot water is not good for brushes).

- 5) Allow the paint to cure for several days, then coat the wand with a clear acrylic varnish such as Grumbacher *Picture Varnish*, or Weber *Univar*. Ordinary wood varnish, shellac or lacquer should not be used.
- 6) Trace the four pieces of the Lotus flower onto sheet metal. A simple heavy-weight aluminum cookie sheet is adequate, and can be cut with metal shears. Those who find work with metal hopelessly difficult may cut the flower from heavy cardboard. On the other hand, those who wish to produce a very elaborate wand may cut the Lotus from wood or solid metal, cast it in metal, or even make it of clay (fired and glazed in the correct colors).

#### THE SECRET TEMPLE / 14

7) Cut around the outsides of the four designs, then smooth the edges with a file and emery cloth.

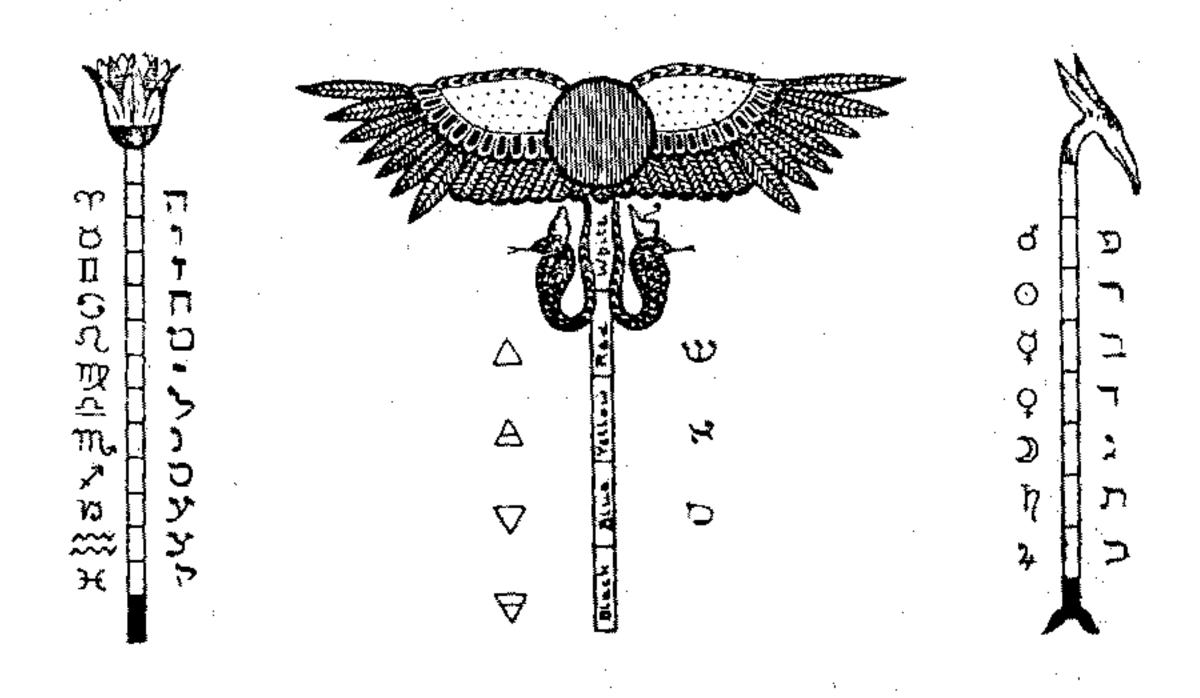

8) Drill a hole in the center of each of the pieces.

9) Using pliers, with cloth padding between them and the metal to avoid indenting the petals, bend the pieces so that they turn slightly inward as if in the process of opening.

10) With a spray metal undercoat paint, cover both sides of the pieces (light coats should be built up). The undercoat must then cure for about twenty-four hours, although it may be dry to the touch almost immediately.

11) Using enamel paints (acrylics will not hold to metal), color the pieces according to directions. If the Lotus is of cardboard, coat the petals with gesso, then finish with acrylics and varnish in a few days.

12) When the pieces are completely dry, attach them to the wand by inserting a small brass screw through the holes into the white end of the painted dowel rod.

## Alternative or Supplemental Wands

Once the underlying principles of the wand are grasped, it may be adapted to suit the temperament of the user. A number of variations on Golden Dawn designs may be considered.

A) Some may prefer to use the wand of the Hierophant. This is a simple shaft with four bands and a crown above. The shaft divisions refer to the five Sephiroth (including Daath) on the Middle Pillar of the Tree of Life.

A crown can be cut from soft wood or metal. Soft metals, such as brass, can be carved using a Dremel *Moto Tool* and metal files, which is not as difficult as some might believe.

- B) An extremely simple variation of the Hierophant's wand can be painted. In this example a dowel is painted red, with five gold bands and a red crown above.
- C) It is also possible to combine the qualities of the Hierophant's wand and the Lotus Wand into a very effective instrument. Here a shaft is carved of 3/4 inch dowel, representing the Serpent Kundalini on the Middle Pillar. The small Lotus is carved from a separate block of wood and painted in the standard green and white. Or it can be carved from brass and left unpainted. The base, symbolizing Malkuth, is quadripartite.

# 3 / The Rose Cross Lamen

This is the second of the instruments to be constructed, and from it are derived the Sigils painted on the other pieces. It is a symbol which synthesizes all of the concepts of Rosicrucian philosophy.

At the center is the Five-Petaled Rose on a golden cross. This represents the Qabalistic principle of the four Elements which are controlled, balanced and activated by a fifth: Fire (Yod), Water (Heh), Air (Vau) and Earth (Heh final) describe the constituent parts of the Personality, ruled by the Higher Self of Tiphareth to which the gold cross is ascribed.

The Rose also stands for the entire manifest Universe. At the highest level of the Tree of Life, Kether is the four Primordial Elements (unexpressed), set toward manifestation by the power of the Unmanifest above the Tree. This principle is explained fully in Regardie's Golden Dawn and in The Qabalistic Tarot\* by Robert Wang.

The twenty-two Hebrew letters around the cross are arranged according to the text of the Sepher Yetzirah: the three inner letters are the maternals, from which all the other letters (i.e., forces of the Universe) are derived. The middle circle contains the simple letters, related to the seven ancient planets. The outermost circle contains the double letters which are the signs of the Zodiac. In all, the letters are the twenty-two mystical Paths on the Tree of Life.

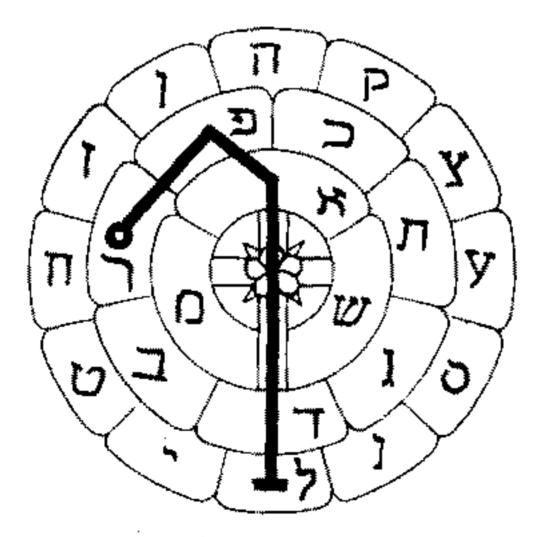

<sup>\*</sup>Qabalistic Tarot. Samuel Weiser, Inc. New York, 1980.

To form a sigil using the Rose, a continuous line is drawn from one Hebrew letter to the next. This is a method apparently developed by the Order of the Golden Dawn. Until the late nineteenth century, such Sigils were derived from traditional magic squares.

For example, let us take the name RAPHAEL, the Archangel related to Air appearing on the Dagger. In Hebrew the name is spelled Resh, Pe, Aleph, Lamed (reading from right to left:

A sigil usually begins with a small circle, and ends with a short line, although this is not essential. All that is really necessary is to trace a line from one letter to the next. If there are two words in a God Name, such as ELOHIM GIBOR (for the Sword) or YHVH TZABAOTH (for the Fire Wand) two separate sigils are required.

Each of the arms of the Cross represents one of the Elements. Here it will be seen that the Hexagram (meaning six planets around the Sun) separates the Earth from direct contact with the Holy Center. This refers both to the Earth as the product of the Fall, and as the receptacle for all of the other Elements.

### THE SIGIL FOR רפאל DERIVED FROM THE ROSE

\*It should be noted that the "Ancient Cypher Manuscripts" of the Order used the traditional Elemental triangles ( ) around the Pentagrams of the Rose Cross. This older form of Elemental symbol is also shown on the Rose Cross Lamen published by Crowley in the Equinox. In the later period of the Order, the Kerubic Signs, shown in the color illustration, were adopted for use on the Lamen. It was believed that they were more effective than the triangles.

#### THE HEBREW ALPHABET

Ж		ALEPH	Α
ב		BETH	B, V
λ		GIMEL	G, GH
ד		DALETH	D, DH
'n		HE	H
ì		VAU	O, U, V
۲		ZAYIN	O, U, V
ħ		HETH	Ch
ָט		TETH	T.
ל		YOD	I, Y
כ	(r)	KAPH	K, Kh
5		LAMED	. [_
מ	(a)	MEM	M
1	(1)	NUN	N
D		SAMEKH	S
ע		AYIN	Aa, Ngh
٥	(ŋ)	PE	P, Ph
አ	(Y)	TZADDI	Tz
þ		QOPH	Q
٦		RESH	R
ש		SHIN	S, Sh
ń		TAV	T, Th

The letters Kaph, Mem, Nun, Pe and Tzaddi take a special form (in parentheses) used when they appear at the end of a word. No such distinction is made on the Rose Cross, and when a final letter appears, it is traced from the general point of the letter.

## Cutting Out the Cross

While the Rose Cross Lamen can be cut from heavy card-board, 1/8 inch plywood is preferable. This should be a hard-wood, such as birch, which has a perfectly flat and smooth surface. Soft building plywood may form ridges when sanded, and should not be used.

- 1) Sand the board lightly, front and back, and coat with gesso. In all cases where wood is used, both sides should be sealed to avoid the possibility of warping.
- 2) When the gesso is dry, sand, apply a second coat and sand again. Sanding should always be done with a sanding block, or with sandpaper wrapped around a flat piece of wood.
  - 3) Draw an outline of the Cross on the board.
- 4) With a coping saw, or an electric jig saw if one is available, cut around the outline of the Cross. A jig saw will keep the edges at a sharp right angle. But, if this is being cut by hand, care must be taken to maintain the straight cut of the blade. Accidental over-cutting is no disaster; errors are easily corrected.
- 5) After cutting there may be some small gaps in the sides of the plywood. These can be filled with one or more coats of gesso. Serious gaps or over-cuts must be filled with plastic wood.
- 6) Coat the sides with gesso. Because of the absorbancy of the end grain, several coats may be required to completely seal the edges.
  - 7) Sand the edges of the Cross.

## Painting the Cross

As with the other wooden instruments, acrylic paints are recommended. A very effective metallic gold paint is also available in artist's acrylic.

There is one media problem, however, which should be considered: All paints tend to cure after a time, and new paint applied over very old paint may not adhere properly. Thus it is best that no more than a few days elapse between painting the undercolors and the symbols. If paint has been allowed to cure for some time, it should be sanded and repainted prior to adding the details.

The most exacting work can be done by those who are comfortable using a ruling pen. The Pentagrams and Hexagram can be drawn with great precision, using this tool and water thinned paint (thick paint will not flow from the pen), although two coats may be required for each line. The same technique can be applied to any straight line on the Cross, such as the divisions of the four Elemental colors on the lower arm.

Admittedly, the use of a ruling pen is difficult, but the more accurately the lines are drawn, the more impressive the overall effect. A pair of dividers is also useful for establishing spacing on the areas around the circle, and for precise divisions of the Pentagrams and Hexagram.

8) With compass and ruler, draw the major sections of the Cross. Eliminate the Pentagrams, Hebrew letters and other details which are to be overpainted on a color background.

9) Apply all of the background colors, including the

petals of the Rose.

10) When the background colors are dry, add the details in colors which are as flashing as possible. Technically, this means using two colors which are exactly opposite each other. The opposite of red is green. The opposite of orange is blue, etc. Some experimentation with color mixing will be necessary before the best result is achieved. This is particularly the case with the Hebrew letters and their background colors.

11) Paint the back of the Cross with a white ground and black symbols. Here, for the first time, we encounter the *Motto* which is painted on each of the instruments. The principle is the same as that of an individual who enters a monastic order and takes a symbolic new name. The magical motto expresses an intention, and each student chooses one according to his or her temperament.

Following are some mottos of original members of the Golden Dawn, which should be considered as samples only. While most of these are in Latin, a motto can be in any

language.

S'Rioghail Ma Dhream (Royal is My Tribe) S.L. MacGregor Mathers

Vestigia Nulla Restrorsum (No Traces Behind) Mrs.
Mathers

Magna Est Veritat Et Praelavebit (Great is the Truth and It shall Prevail) William Woodman

Sapere Aude (Dare to be Wise) Wynn Westcott

Demon Est Deus Inversus (The Devil is God Turned About) W.B. Yeats

Iehi Aour (Let There Be Light) Alan Bennett Perdurabo (I shall Endure) Aleister Crowley

Sacramentum Regis (The Sacrament to the King) A.E. Waite

12) Once the front and back are completed, the sides of the Cross should be painted. The same acrylic gold used for the central cross is appropriate, since the Lamen relates to Tiphareth. As was undoubtedly discovered in painting the central cross, several coats of acrylic gold produce a very translucent and glowing effect.

### The Colors

Extreme center of Rose = white

Rose = red

Leaves = green

Central cross = gold

Uppermost arm = yellow background, purple symbols

Left arm = red background, green symbols

Right arm = blue background, orange symbols

Bottom arm = top part: white, black symbols

bottom part: citrine (somewhat dark to accomodate the white pentagram) olive, russet, black. Symbols are white.

The colors on the Rose are those of the King Scale, and are those of the Paths attributed to the Hebrew letters in Atziluth, the World of Pure Spirit. These are found in the section of *The Golden Dawn* entitled "Concerning the Tree of Life," and in Crowley's 777.

- א 11 Bright pale yellow
- ⊃ 12 Yellow
- ٦ 13 Blue
- 7 14 Emerald Green
- ក 15 Scarlet

- า 16 Red-orange
- 7 17 Orange
- n 18 Amber
- ט 19 Greenish-yellow
- > 20 Yellowish-green
- ⊃ 21 Violet
- 5 22 Emerald Green
- 23 Deep Blue
- ש 24 Green-Blue
- b 25 Blue
- ע 26 Indigo
- 9 27 Scarlet
- צ 28 Violet
- P 29 Crimson (ultra violet)
- ז 30 Orange
- ש 31 Glowing orange-scarlet
- រា 32 Indigo

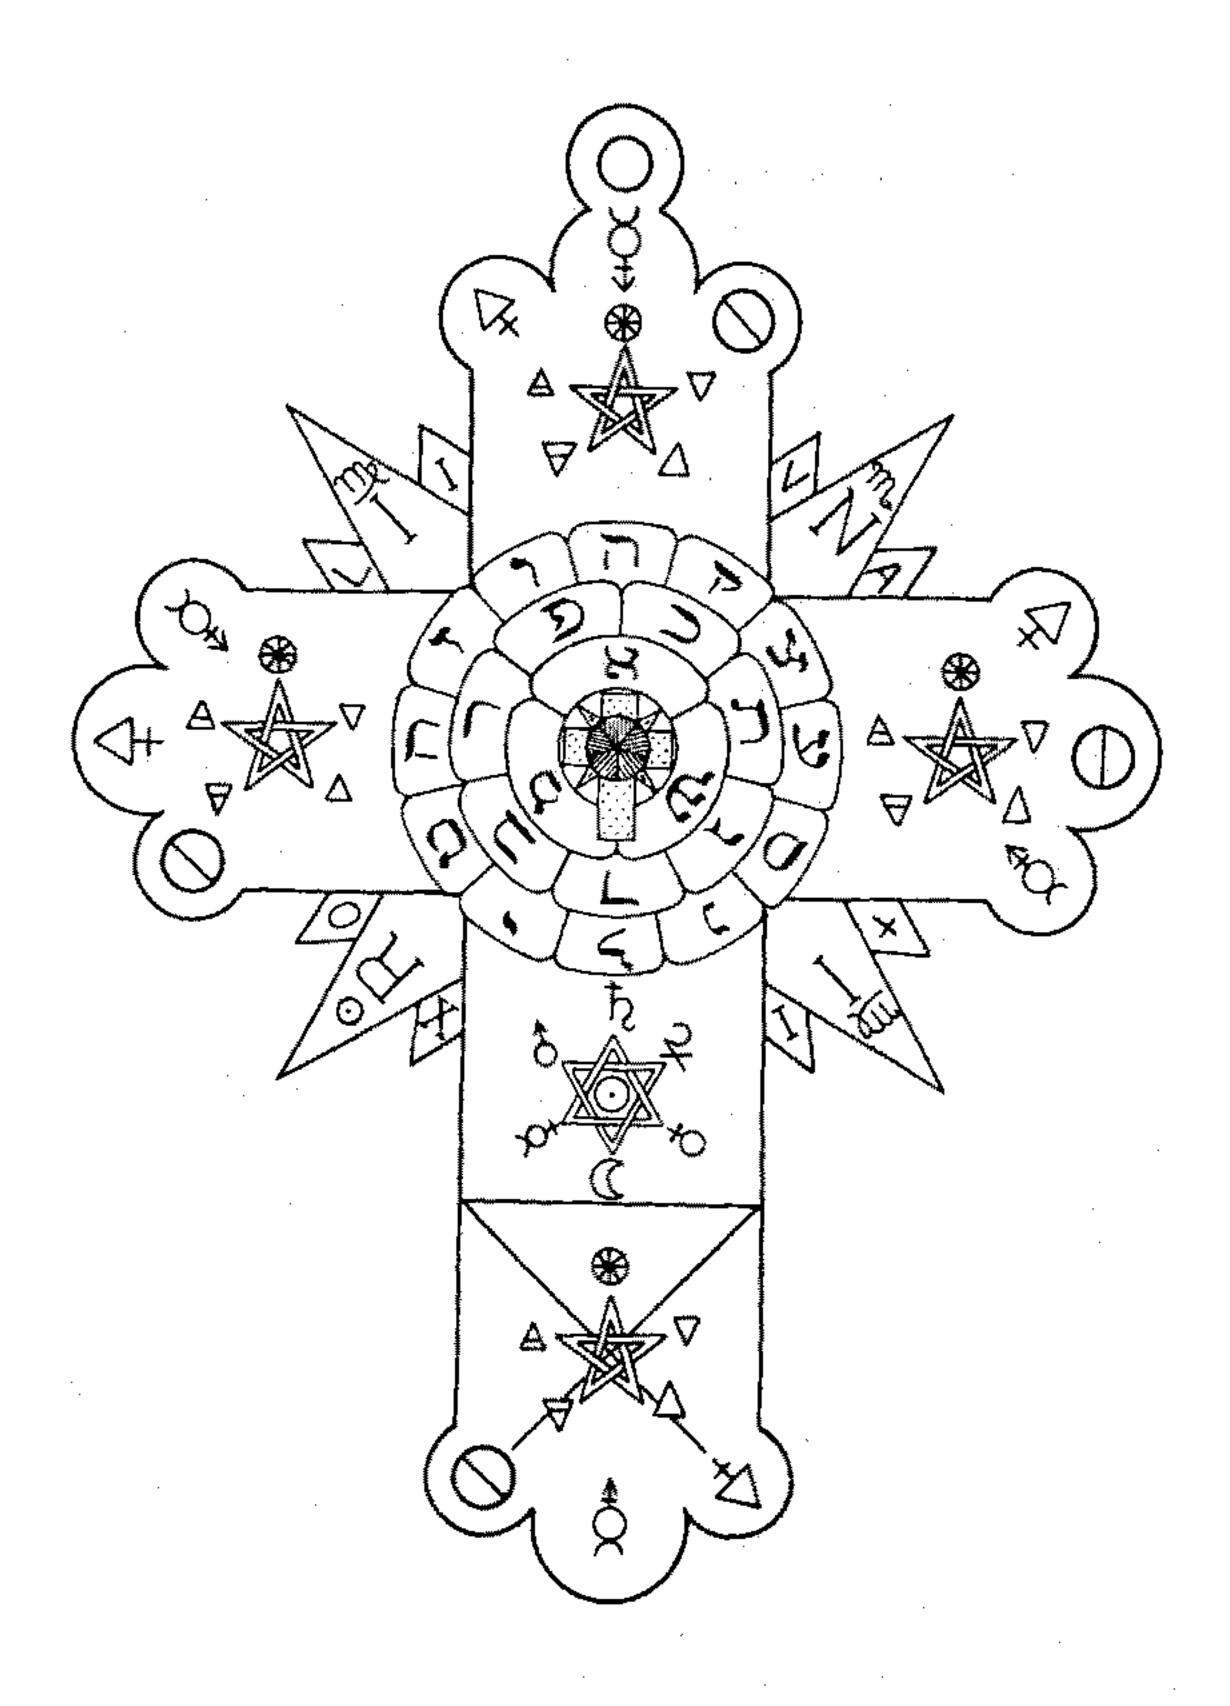

The opposites of all of these colors can be worked out using a color wheel.

### Finish

After the paints are thoroughly cured, which should take several days, the Cross must be coated with a non-yellowing acrylic varnish such as that used on the Lotus Wand. A second coat of varnish is generally advisable.

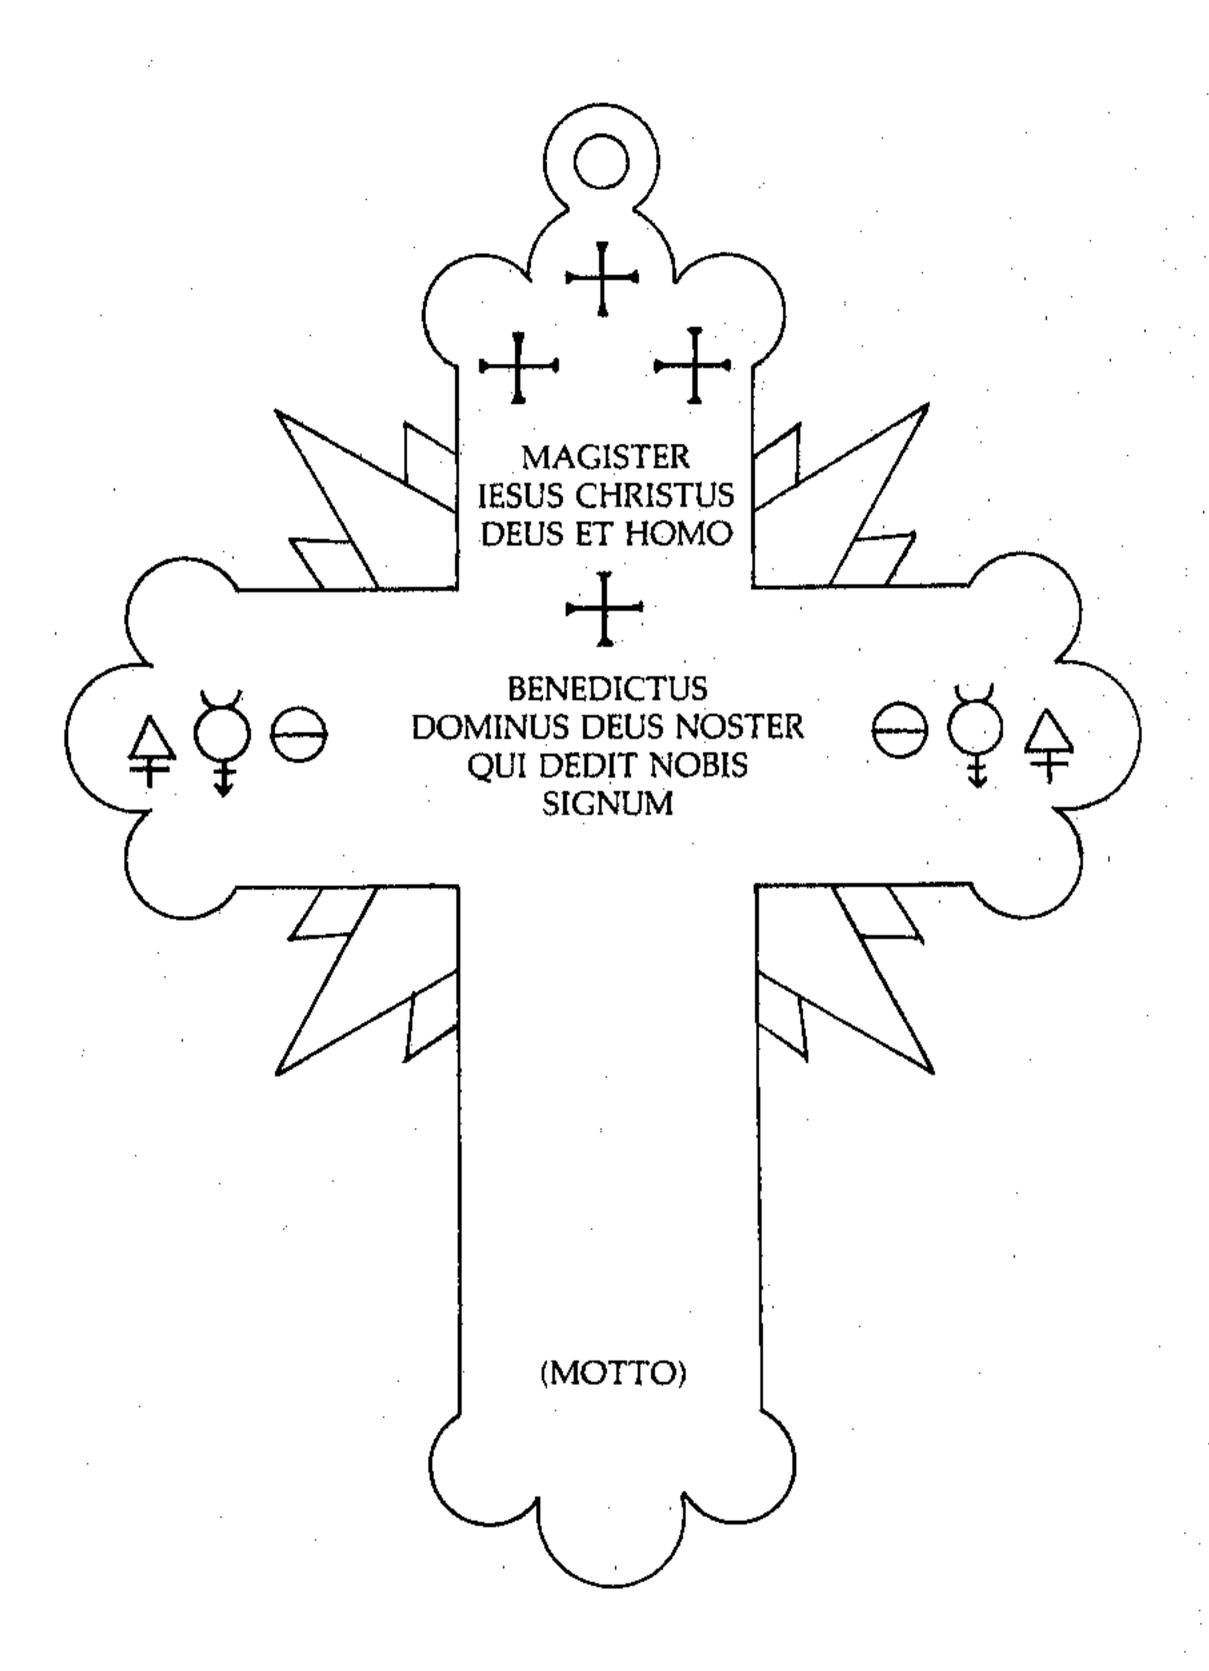

Finally, the Cross is suspended from a yellow colarette. Silk is preferred, but a synthetic fabric is adequate. The colarette should be made of two pieces of fabric, interfaced with muslin to give it body.

The Cross is then attached, using either a heavyweight thread or a metal ring of some kind. Rug-button thread, embroidery floss or waxed jeweler's thread are all excellent for this purpose. A metal ring can be made from heavy wire, bent with pliers or a special bending jig. Metal rings are also available from jeweler's supply companies.

#### THE ROSE CROSS LAMEN

From Aleister Crowley, *The Equinox*, Vol. 1, No. 3. This is the older version of the Rose Cross, as described in the Golden Dawn *Cypher Manuscripts*, using triangular symbols of the Elements, rather than the four Kerubic Emblems.

THE ROSE CROSS LAMEN: REVERSE

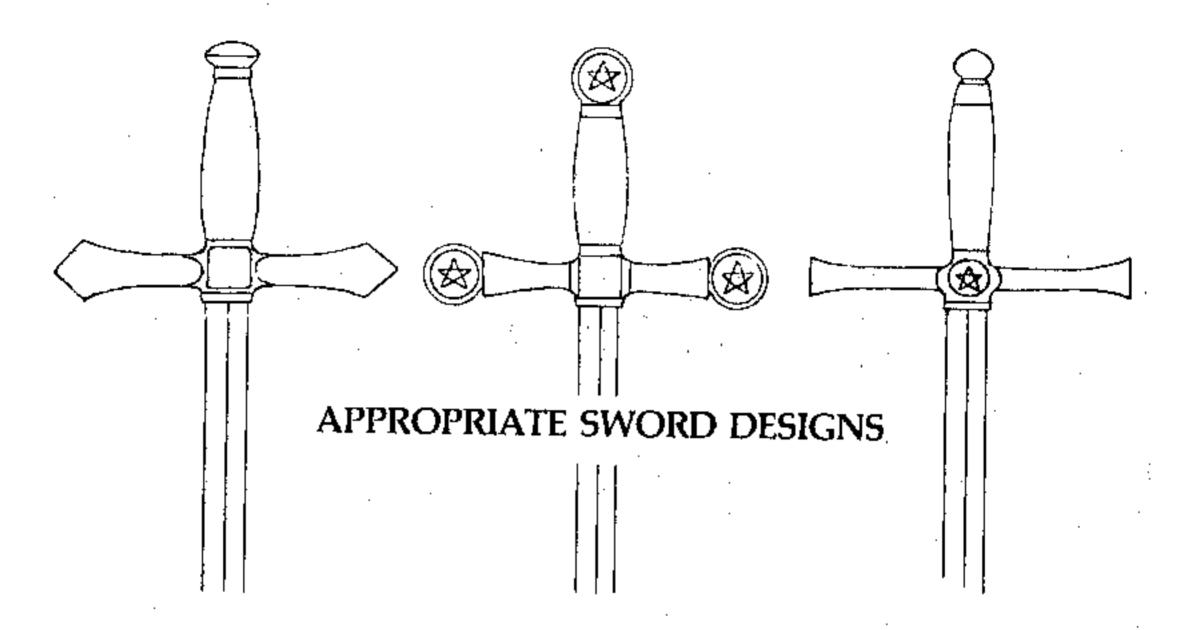

## 4 / The Sword

The Magical Sword is used in all instances where great force in invocation, evocation or banishing is required. It is an instrument relating to the fifth Sephira, *Geburah* (Strength) on the Tree of Life. Thus, the *Pentagram*, or five pointed star is one of its key symbols.

The assumption will be made that very few readers of this book are blacksmiths, and that those who are will require no instruction on forging their own sword from solid metals. Most of us find it necessary to purchase a sword, and paint it according to the traditional directions.

The Golden Dawn text states that: "Any convenient sword will do." However, this suggestion was made at a time when swords actually were conveniently available, being often required for Victorian ceremonial use. Swords available today in antique shops, most of which are from the nineteenth century, tend to be overly ornate and of little use because they offer no room for painted inscriptions. Thus, the student is advised to purchase a modern sword designed specifically for ritual use from an occult or Masonic supply house. Such swords are usually far less expensive than antiques.

Choose a sword which is not too heavy, preferably one with a wooden handle and a simple cross bar of brass. The latter should be fairly wide, to allow for the painting of symbols, God Names and sigils.

## Painting the Sword

- 1) If the wooden handle has been coated with enamel or varnish, which is likely, remove the finish completely using a semi-paste paint remover. When down to bare wood, sand, coat with gesso and sand again lightly.
- 2) Rub the metal parts of the handle with medium emery cloth. This will give the metal 'tooth,' helping to hold the undercoat paint. The most serious risk in painting metals is that the paint will adhere improperly and flake off. Careful preparation of the surface, and undercoating, minimizes this possibility.
- 3) With masking tape and strips of newspaper, cover the blade and the gesso-coated wooden handle.
- 4) Spray the metal areas of the handle with undercoat. When this is dry to the touch, remove the masking and clean any areas where the paint has run or oversprayed. Then allow the Sword to dry overnight.
- 5) Color the handle bright red using acrylic paint. With enamel, also bright red, color the metal parts. Try to choose colors which are as similar as possible, so that the difference in media will not be obvious.
- 6) Paint all sigils, God Names and the Motto. These are to be a very bright green, so that they will flash on the red background. All Names are in Hebrew, and should be painted with care and respect. Each letter is, in itself, a magical symbol of great power.

After the Names and sigils have been completed, retouch as necessary, using the background reds. If a few hours elapse between painting the background and symbols, mistakes can easily be corrected. A false start can be lifted off with a cotton swab dipped in water if using acrylics, or turpentine for enamels. If this is done very carefully, the background paint will not be picked up.

There are nine sets of symbols to be applied to the Sword: seven God Names and their associated Sigils, the Mot-

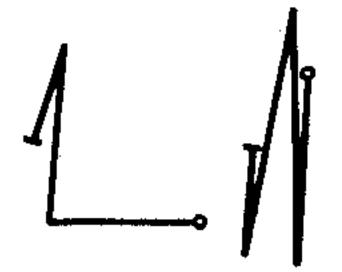

to, and Pentagrams to fit the design of the Sword:

I) THE GOD NAME OF GEBURAH AND ITS SIGILS: ELOHIM GIBOR

- II) THE ARCHANGEL OF GEBURAH AND ITS SIGIL: KAMAEL
- III) THE CHOIR OF ANGELS OF GEBURAH AND ITS SIGIL: SERAPHIM
  - IV) THE HEBREW NAME OF THE PLANET MARS AND ITS SIGIL: MADIM
  - V) THE ANGEL OF THE PLANET MARS AND ITS SIGIL: ZAMAEL
  - VI) THE INTELLIGENCE OF THE PLANET MARS AND ITS SIGIL: GRAPHIEL
  - VII) THE SPIRIT OF THE PLANET MARS: BARTZABEL VIII) THE MOTTO
  - IX) PENTAGRAMS BALANCED AROUND THE SWORD

IX. PENTAGRAMS

# 5 / The Fire Wand

This is the first of the Elemental Weapons, symbolic of the Forces of the יהוה . The Wand, Cup, Dagger and Pentacle are also the four symbols of the Tarot.

The Fire Wand presents a special problem in that it must have a magnetic wire running through its center, from one end to the other. Here again, one may wish to simply purchase the wand ready-made, although its construction is not so difficult as it might appear.

### Construction

Because the Fire Wand is approximately ten inches long, drilling from one end of a piece of dowel to the other would be a difficult task for the average craftsman. Consequently, it is expedient to saw a one inch dowel rod lengthwise, insert the wire, and glue the pieces back together.

Some writers (in discussing magician's wands) emphatically insist that to insert a wire in this way should never under any circumstances be done, because it destroys the integrity and purity of the rod. But that advice is anachronistic. The seventeenth, eighteenth and nineteenth centuries saw the publication of many books purporting to describe the tools of magical work. The supposed requirements were so stringent as to discourage those who lacked sufficient commitment to the real task of spiritual development. We may suppose that those who

refused to be discouraged, and who were intended to follow the ritual Path, found guidance in understanding what is and what is not actually important.

- 1) With a coping saw, cut a carefully-braced 1 inch by 10 inch dowel rod in half lengthwise. This is best done with a small vice, an inexpensive piece of equipment which is a *must* for constructing these instruments, at least for those who do not consider the sudden removal of a finger a significant part of their magical training.
- 2) Take a piece of steel wire 1/16 inch in diameter by 10-1/8" long, and repeatedly move a strong magnet across it in one direction, until it becomes sufficiently magnetic that it will pick up a pin. The end which attracts the pin will go at the conical end of the wand.
- 3) Cut a slight groove in both pieces of the rod, so that the wire will fit into it.
  - 4) Insert the wire so that it extends 1/16 inch at each end.
- 5) Apply a very thick glue, such as Hideskin, to both pieces of the wand. This heavy glue will compensate for the wood lost in cutting the rod apart.
- 6) Push the two pieces together lightly, so that some glue is squeezed out, and the original cylindrical form of the rod is restored.
  - 7) Allow the wand to dry overnight.
- 8) Fill gaps with plastic wood and/or gesso, allow to dry thoroughly and sand.
- 9) Measure the sections of the Wand, marking them with pencil. A rolled piece of cardboard will serve here, as it did on the Lotus Wand.
- 10) With a wood rasp, files, knives, etc., carve the conical end piece. Then cut away the three main sections, leaving four bands.

There are, obviously, a number of ways in which this wand could be made. It could be made in two main pieces: the conical end being carved separately and glued to a 3/4 inch shaft, with subsidiary bands of cardboard or other material glued around the outside. It could also be cut on a lathe.

11) Smooth the wand first with a heavy, then with a fine sandpaper.

12) Apply two coats of gesso, sanding lightly between each coat.

13) Color the red parts of the wand using artist's acrylic

paint.

14) Color the yellow bands and the Yods on the endpiece (Do not paint the bits of steel which extend from either end). Acrylic yellow tends to be very transparent, and any streaks of red underneath will show through. If there are any smeared areas of red, coat these with white acrylic and then two coats of yellow.

15) Paint the God Names and Motto in a very bright

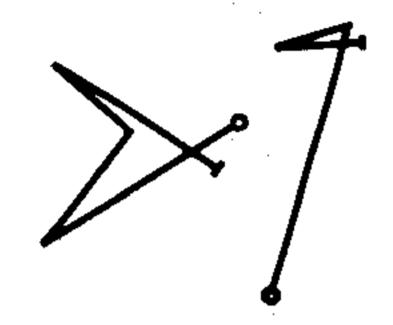

flashing green.

16) When the paint has cured completely, apply acrylic varnish.

The symbols to be painted on the Fire wand are:

- I) THE GOD NAME: YHVH TZABAOTH
- II) THE ARCHANGEL: MICHAEL
- III) THE ANGEL: ARAL
- IV) THE KING: SERAPH
- V) THE RIVER OF PARADISE RELATING TO FIRE: PISON
- VI) THE CARDINAL POINT (SOUTH): DAROM
- VII) THE HEBREW NAME OF THE ELEMENT: AESCH
- VIII) THE MOTTO

VIII. THE MOTTO

# 6 / The Water Cup

This instrument is one which may offer real challenge to those with artistic talent. The Golden Dawn instructions suggest that any glass cup (with a stem) may be used, and paper petals applied to its sides. This seems the most aesthetically unsatisfying of all possible solutions, although it appears to have been the most common method of producing the Cup.

If there were an absolute ideal, it would be a cup cast in silver and enameled. This however, for most, is as impractical an idea as cutting a sword from raw metal.

The Water Cup has eight petals which may be painted, but which are extremely beautiful if cast or carved. Carving is the most reasonable solution for those who desire the raised effect. The Cup shown in the color illustration was an inexpensive reproduction of an eighteenth century American pewter cup, cast in relatively soft metal. The petals were cut away using a Dremel *Moto Tool* and metal files, a slow and tedious process. The same result can be achieved using a wooden cup.

Another possibility is to build the cup from clay, and then fire it with the appropriate color glazes. To do this it is necessary to have some knowledge of glazes, which change colors in firing. However, many ceramic artists and art schools will offer advice, and will fire pieces for a minimal charge.

What will be described here is the process for adapting a Water Cup from some stock metal or wood cup. Those who do

not wish to carve the petals may begin with number 5 of these instructions.

This Cup should not, incidentally, be confused with the separate Cup required for the performance of a Eucharist. It is to be used specifically for operations involving the Elements, whereas a Cup (Chalice) for Eucharistic purposes is symbolic of the Christ-Buddha center of Tiphareth. By the same token, the Air Dagger is not to be used where the Golden Dawn documents call for a knife, in the Lesser Banishing Ritual of the Pentagram. Here too, a separate tool (of no special design) is required.

- 1) Prepare the surface of a metal or wooden cup. If a cast metal cup is used, smooth the surfaces with emery cloth and files, as necessary. If a wooden cup is used, it is likely to have been varnished. In that case the finish must be removed with a paste paint remover.
- 2) Measure eight equal petals around the outside of the Cup. Draw the outline of the petals using a soft pencil.
- 3) On metal: With the electric cutting tool and a fine bit, incise over the pencil lines: On wood: Incise over the pencil lines using an electric cutting tool, knives, or woodcut gouges.
- 4) On metal: Slowly cut away the areas around the petals, using a large, round bit. Be careful to avoid the incised lines. Then replace the large bit with a smaller one, and cut precisely to the edge of each petal. Metal files and emery cloth of different coarseness will be required for retouching and smoothing out the cuts. On wood: follow the same procedure if using an electric tool, or use different wood gouges as required. A wood rasp is a very useful tool for this job. Retouch the petals with files and rought sandpaper.

The cutting may be extremely simple, or it may involve considerable detail. It should be noted that petals on a wooden cup can also be built up with *Gesso Modeling Paste*. This is a medium of ground marble chips which dries very hard, but can be carved. It is often used to decorate frames. Care should be taken to build this material up in slow coats, as it tends to crack. Cracks are, however, easily filled with more of the paste, which sands to a beautiful and smooth finish.

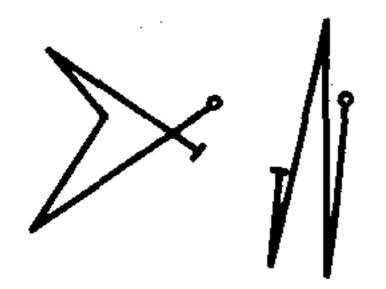

5) Finish the surface of the Cup using fine emery cloth on metal, and fine sandpaper for wood.

- 6) On metal: With masking tape, cover all areas of the Cup except the petals. Spray the petals with a metal undercoat and allow the paint to dry overnight. On wood: coat the entire Cup, inside and out, with gesso. Sand lightly when dry and apply a second coat.
- 7) On metal: color the petals with a rich enamel blue. When this is dry, add the orange borders and the inscriptions. On wood: with artist's acrylics, paint the inside of the Cup and the area outside the petals either a metallic silver or a light blue. Then paint the petals a darker blue and the borders and inscriptions orange.
- 8) If using wood and acrylic colors, apply two finish coats of clear acrylic varnish when the paint has adequately cured.

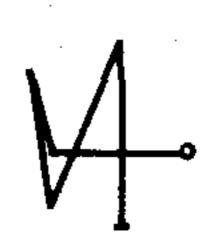

The symbols to be painted on the Water Cup are as follows:

- I) GOD NAME: ELOHIM TZABAOTH
- II) ARCHANGEL: GABRIEL
- III) ANGEL: TALIAHAD
- IV) RULER: THARSIS
- V) RIVER OF PARADISE RELATING TO WATER: GIHON
- VI) CARDINAL POINT (WEST): MAARAB
- VII) HEBREW NAME OF THE ELEMENT: MAYIM
- VIII) THE MOTTO

# 7 / The Air Dagger

Like the Sword, the Dagger should be purchased in a 'raw' state, and painted according to the traditional instructions. Suggestions for painting the Dagger are precisely the same as for the Sword, including the use of acrylic for the wood handle, and enamel for the metal parts.

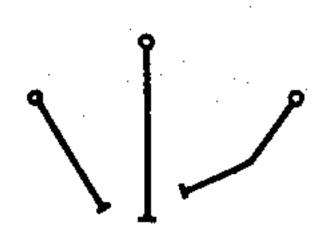

The background color is a bright yellow, while the color

of the God Names and sigils is violet.

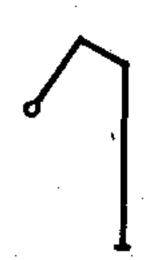

The Names to be painted on the Air Dagger are:

- I) GOD NAME: SHADDAI EL CHAI
- II) ARCHANGEL: RAPHAEL
- III) ANGEL: CHASSAN
- IV) RULER: ARIEL
- V) RIVER OF PARADISE RELATING TO AIR: HIDDIKEL
- VI) CARDINAL POINT (EAST): MIZRACH

# 8 / The Earth Pentacle

Of all the instruments, the Pentacle is the most easily constructed. It is nothing more than a painted disk of plywood, which can be purchased ready-cut from a hardware, hobby, or lumber dealer. If such a disk is not available, one can be cut with an electric circle-cutter attached to a drill, or by hand. If, however a circle cutter is used, it *must* be held in a drill press. Otherwise it is an extremely dangerous tool.

1) Using a compass, draw a circle 4-1/2 inches in diameter, on a piece of 1/2 inch thick birch or other hardwood plywood.

2) With a coping saw or electric jigsaw, cut around the outline of the circle.

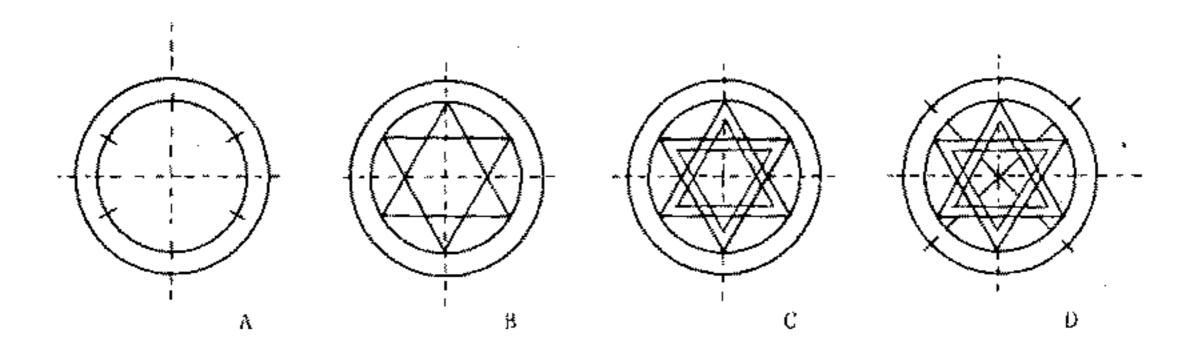

3) Correct any imperfections in the circle with a wood rasp or file, making the edges slightly rounded if desired.

4) Fill any gaps or gouges with plastic wood, allow to dry, and sand very smooth.

5) Cover the front and back of the disk with two coats of

gesso, sanding between coats.

6) Relocate the center hole made by the compass point, and scribe a circle around the Pentacle, with approximately the spacing shown in figure A. Then draw a † at the center of the circle. Finally, with dividers, separate the circle into six even parts, beginning at the intersection of the top of the circle and the verticle line of the cross.

- 7) Draw lines connecting the six points, as shown in figure B.
- 8) Draw a second set of lines inside the first, as shown in figure C.
- 9) Divide the quarters created by the cross in half, then draw lines from these points, creating a second, diagonal cross to be painted in the four colors of Malkuth. This is shown in figure D.
- 10) Repeat the process on the opposite side of the disk. Here some trial and error with the compass may be required to locate the exact center of the disk, as is necessary to draw the outer circle.

On both sides the central compass hole should be well-defined, sufficiently so that gesso or other paint will not fill it in completely. This is important because circular guidelines for the God Names and sigils must be drawn on top of the white border.

11) Apply the various colors:

EDGE = white BORDER = white HEXAGRAM = white TOP QUARTER = citrine LEFT QUARTER = russet RIGHT QUARTER = olive BASE QUARTER = black INSCRIPTIONS = black

This can be done entirely with a small brush, but a combination of brush and ruling pen will produce the cleanest lines.

Since the *citrine*, *olive* and *russet* must be mixed from other colors, it is recommended that this be done in small pieces

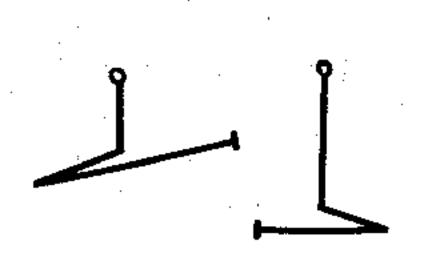

of aluminum foil. The foil can be curled up into a ball, which will keep the paint from drying for some time, and available for the inevitable retouching as paint is smeared on finished parts of the Pentacle.

- 12) When the quardripartite central area and the Hexagram have been painted, use the compass to draw two light guidelines on the white outer band. The inscriptions are then painted between these guidelines. When the inscriptions are dry, the guidelines are easily removed with a kneaded eraser, or touched-up with white paint.
- 13) After both sides of the Pentagram have been painted and allowed to cure thoroughly, apply two coats of clear acrylic varnish. This varnish is washable, which is especially important here, as the Pentacle may pick up finger smudges over a period of use.

The Names to be painted on the Earth Pentacle are:

- I) GOD NAME: ADONAI HA-ARETZ
- II) ARCHANGEL: AURIEL
- III) ANGEL: PHORLAKH
- IV) RULER: KERUB
- V) RIVER OF PARADISE RELATING TO EARTH: PHRATH

### Wrapping the Instruments

As each instrument is completed it should be wrapped, although this must not be done until the paint and varnish have thoroughly dried. Appreciating that the instruments are charged in their manufacture, it is advisable that they be wrapped as soon as possible to contain whatever energies have been bestowed to the piece. Of course, an instrument must be wrapped after it is has been ritually consecrated.

Instruments are traditionally covered with an appropriate colored silk, i.e., red for the Sword and the Wand, blue for the Cup, yellow for the Dagger, black for the Pentacle, white or gold for the Lamen and white for the Magician's Wand. Silk has some unusual insulating qualities, which serve to con-

tain the charge held by the instrument.

Unfortunately, silk has become very expensive and few fabric stores today carry it, even in white. This being the case, linen, a natural fabric which serves almost as well, is recommended. The most practical linen is off-white rough weave, which has the added advantage of being extremely easy to sew; large stitches are not obvious.

A separate bag or hemmed cloth must be made for each of the instruments. This may be designed so that it is tied with a cord, folds over at the top, or is sealed with a snap or zipper. If, however, a zipper is used, it should be inserted in such a way that it cannot possibly scratch the paint on the instrument. Bags may also be lined, in color if desired. Any fabric, such as an inexpensive acetate, is acceptable so long as the outer material is pure linen or silk.

# Part II / The Temple

# 9 / The Temple

It might be safe to guess that in the Victorian era more of those pursuing esoteric ritual had their own private Temples than do today. Houses were large, and the late nineteenth century architectural aesthetic dictated that living space have a certain beehive quality. So to find an unused room and lay claim to it may not have been such a luxury.

Today apartment living and houses of two or three carefully-planned bedrooms is the norm. And to consecrate an entire room for ritual and meditative purposes may be all but impossible. Those who can prepare such an individual space can count themselves very fortunate. Those who cannot must exercise ingenuity: some may have an Altar which sits inconspicuously disguised in the corner of a livingroom. Others may choose to build an elaborate cabinet which closes off when not in use.

For the person living alone, or with a spouse who is either sympathatic or shares these convictions, finding space may be the primary difficulty. But for those with curious children or fundamentalist Christian relatives, the less that is obvious, the better.

There are four possibilities, here offered in order of their respective worth:

1) Set aside a separate room. Only the student should enter this room, or those who are sharing meditative and ritual

exercises. In this case a very complete Temple can be developed, with a central Altar, large columns and Enochian Tablets permanently affixed to the walls at the four Cardinal points. This is the ideal. There is really no substitute for a room which is duly consecrated and sanctified through frequent use. It becomes a silent and sacred place which effects a transformation on the person who enters it.

2) Design a large cabinet into which can be fit an Altar, columns, Banners, etc. It is best to purchase an old cabinet and adapt it as necessary. Such cabinets are readily available through antique dealers, and usually at good prices since they were made for the larger homes of the past and are now in small demand. A cabinet should be chosen which is built very low to the ground, or which can be adapted to move the Altar in and out of it easily. Many rituals require what is called *circumambulation* of the Altar, a complete circling of the Altar which invokes or banishes the Light, depending upon the direction of movement.

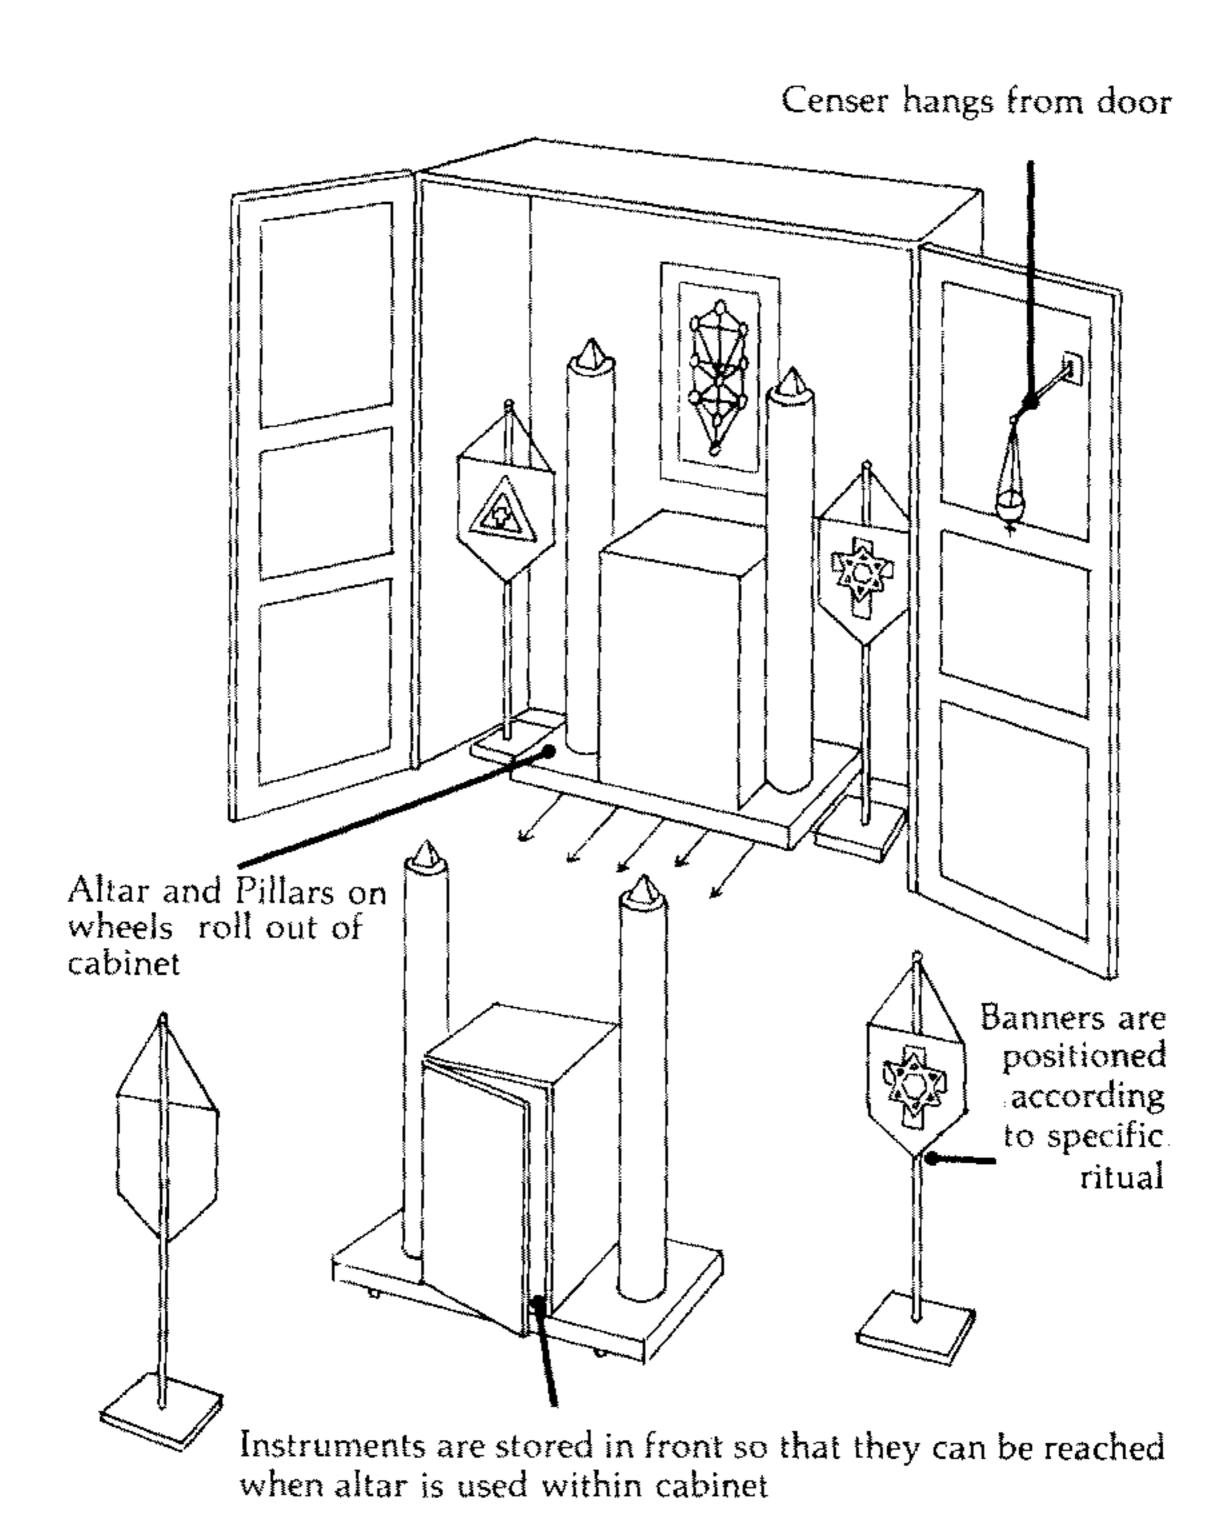

In the suggested design, the Pillars and Altar are on a moving platform which can be wheeled into the center of a room as necessary. The Banners of the East and West are stored beside the platform, rather than on it and are positioned according to the different rituals. The Pillars, also can be moved from the platform as required.

Normally, instruments are stored at the back of the Altar. However in this case, they are stored at the front to permit access when the Altar is in the cabinet.

- 3) An Altar may be constructed which houses all of the instruments, two miniature columns, the Banners and Tablets, and other miscellaneous equipment. Such an Altar may be wheeled in and out of a closet. Or it can be designed in such a way that it appears to be an ordinary chest, decorating a room.
- 4) The last suggestion is for those who have no way whatsoever to house an Altar.

It is important, at very least, that the instruments be stored in some way which is 'special.' They should not merely rest in a dresser drawer, but should be kept so that they are separated, conceptually, from daily life. It is possible to create a very effective Temple without a formal Altar, and using completely portable materials.

#### SUGGESTED DESIGN FOR A TEMPLE CABINET

The description which follows here is of the construction of a complete private Temple according to the Golden Dawn Tradition. While the various elements may be simplified to the

#### THE SECRET TEMPLE / 54

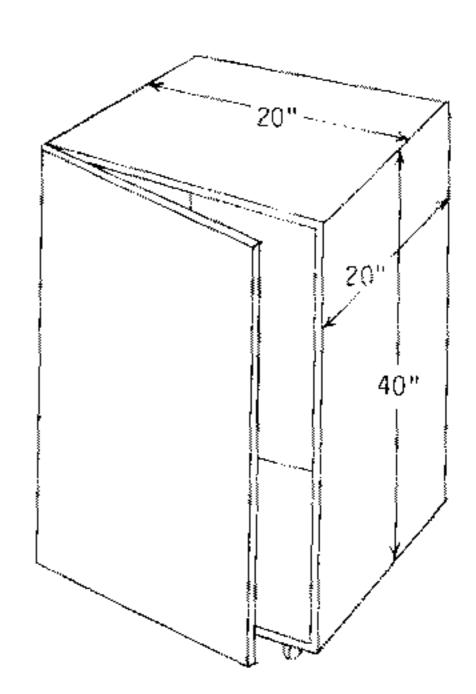

extent that they will fit into a small trunk, they may also be expanded in detail and majesty such as to be the worthy Temple of an occult order.

## 10 / The Altar

The Altar of the Mysteries is a double cube, painted black. It refers to Malkuth, the base Sephira on the Tree of Life. Thus it is understood that while it appears black overall, the four sides are to be visualized as being Citrine, Olive, Russet and Black, respectively.

It is not necessary to actually construct two separate cubes, and link them together, as the "double cube" refers to dimensions. In fact, space must be left behind the Altar for storage of the Magical Instruments, as the Sword is so long that only the full length of the Altar would contain it.

1) Cut or purchase six pieces of 1/2 inch birch plywood in the following dimensions:

- 2) Drill screw holes, and gouge areas for counter-sinking (insetting of the screw head). Then assemble the pieces with screws and wood glue.
  - 3) Attach the door with hinges and a small latch.
  - 4) Attach wheels on flat plates to the bottom.
- 5) Fill the counter-sunk screw holes with plastic wood, patch as necessary and sand when dry.
- 6) Apply undercoat, then one or more coats of black enamel.

## Altar Coverings

It is not necessary that the Altar be covered, but a cloth of some sort will make it significantly more attractive. Moreover, a student who has no Altar may find an Altar cloth, whether simple or elaborate, very useful.

The more the Temple, whether a permanent room or entirely portable, is set apart, the more effective it becomes. And the student who lavishes attention on the preparation of a cloth will find that it lights up the environment whenever it is unfolded and spread onto the simplest table. The cloth, in effect, becomes the Altar.

The Banners of the East and West, to be presently considered, are a difficult craft project, even for those with considerable sewing experience. Such is not the case with an Altar cloth, which can be nothing more than a large black square with hemmed edges. The most ornate borders of gold are available by the yard in fabric stores, and are quite inexpensive and easily applied by hand or by machine.

The Altar illustrated in color has two coverings, both of which are simple black material with stock border decorations applied. The Rose of Five Petals, surrounded by the emblems of the Four Kerubim, is hand-embroidered and represents one individual approach to the Altar covering. A black cloth with no decoration whatsoever is acceptable, but the more attention to detail, the more there is a psychological separation from daily life, and the more attention is directed to the inner realities which the Temple represents.

It must never be forgotten, however, that no matter how beautiful the instruments and the Temple we create, they are

merely a means to an end. We mold these things from dust, and, like us, they will return to the dust from which they were created. They served us for a split second in eternity.

## 11 / The Lamp

Traditionally, an oil lamp burns above the Altar as a sign of the Illuminating Divine presence. Such a lamp is an extremely basic device, consisting of nothing more than a shallow bowl filled with oil and a wick. A piece of heavy string will serve as a wick, and olive oil can be burned.

The lamp pictured in the color illustration is a Temple lamp, made in France. The small cup which hangs beneath it collects oil which drips slightly over the lip. Such lamps are still being manufactured.

## 12 / The Censer

Incense is extremely important to ritual, and two forms of incense holders are required. The first is a dish filled with sand, used to hold sticks of incense for rituals such as that of the Rose Cross. The second is the censor, a part of the Temple furniture which hangs in the West or north-west corner of the altar.

A piece of self-starting charcoal, sold in church supply stores, is placed in the censer, ignited, and incense such as frankincense dropped on top of it. It should be added that very little charcoal is required, particularly in a small space. Large charcoal blocks intended for church use should be broken into small pieces. Naturally, care should be taken in the use of charcoal since it releases dangerous carbon monoxide; adequate ventilation must always be provided.

It might be mentioned, parenthetically, that one authority believes some of Eliphas Levi's visions to have been the result of carbon monoxide poisoning, which is certainly possible. The least that can be stated with scientific certainly is that burning vast amounts of charcoal in a small, unventilated, space may lead the occult student to a longer out of the body experience than had been planned.

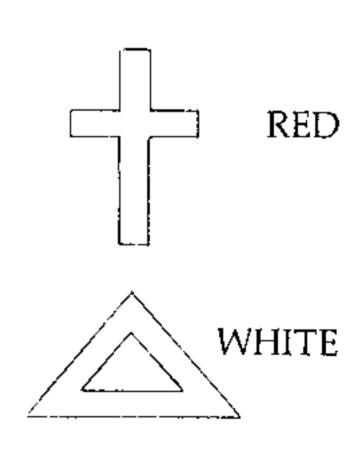

An elaborate censor can be purchased at a church supply store, although it is likely to be quite expensive. And the unfortunate fact is that most of the liturgical brass being produced today is of poor quality metal work, and execrable design. One

#### THE SECRET TEMPLE / 60

possible solution is that shown in the color illustration here: the censer was adapted from a modern chinese incense burner, intended to stand on a table. It was selected because of the fish on the cover, which is a Christ-Tiphareth symbol. Almost any small incense burner can be made into a censer by drilling holes in the sides, and suspending it from chains.

## 13 / The Cross and Triangle

Golden Dawn rituals which require the use of the Elemental Weapons also require a *Red Cross* and *White Triangle* at the center of the Altar. These can be cut from thin plywood and painted, or they can be made from cardboard. A more ambitious possibility is that they be sewed onto the center of a black altar cloth, using red and white fabrics, or embroidery.

The Cross and Triangle should be no larger than three or four inches high since, when all of the instruments are placed around them on the altar, there may be little space left.

• 

•

.

. .

## 14 / The Pillars

Traditionally the Pillars stood at the doorway of the mysteries in the ancient Temple of Solomon. They represent the dualities of the earthly condition, brought into balance by the candidate who stands between them.

One is white and the other black. Both are crowned with a red triangle and pyramid having a light with a hidden source. The black Pillar is painted with white Egyptian figures, a black lotus and a black cube at its base. The white Pillar is painted with black Egyptian figures, a black lotus, and also rests on a black cube.

This describes the perfect Golden Dawn column. Those shown in the color illustration, however, are a simplified version having neither the base, inner light, nor hieroglyphic inscriptions. The Pillars may be either the most complex pieces of furniture in the Temple, or the most simple.

A Pillar may be nothing more than an upright piece of wood, round or square, on a flat base. It may be as small as two or three feet if space presents a problem.

## The Complete Golden Dawn Pillars

From the standpoint of Temple construction, Americans have one special advantage, resulting from their countrymen's mania for destroying old buildings. In every major city nineteenth century row houses, with wood porches, are either being

systematically razed or renovated to exclude the porch. This means that piles of large wooden pillars are usually available in salvage yards, and at virtually give-away prices. The columns illustrated here began life on a Victorian porch in Baltimore.

Such pillars can be constructed, but that is a tedious and costly task. Of course, if a Temple is to be constructed for the use of an occult Order, cost may be less of a consideration, and designs should be turned over to a master cabinet-maker. A Temple for group work should come as close to the ideal as possible.

If old pillars are located, a number of potential problems exist. First, a great many such pillars have been stored in outside yards, and are badly rotted. These should be avoided. It will also be discovered that most of these pillars are made of hardwood strips, grooved together, and nailed to a porch base. Not only are they extremely heavy, but there is a likelihood that there will be a number of dangerously protruding, or slightly hidden, rusty nails. Carry a pair of pliers into a scrap yard, and expect to have to pull out some nails before transporting the old pillars.

The greatest difficulty is that old pillars generally have many decades of paint on them, invariably chipping off. Cleaning this paint to bare wood requires a large amount of heavy duty paint remover, and many hours. Moreover, the solvents required to handle such caked paint are extremely toxic and volatile, so work should be done out of doors if at all possible.

The most practical solution is to take the pillars to a company which specializes in removing paint from old furniture where they can be dipped or sprayed with solvent.

Beginning with clean columns, whether renovated, or built new:

- 1) With 3/4 or 1" birch plywood, construct two cubes (leave the bottoms open) and attach the columns securely. If using new columns, work with several very long screws and an industrial-weight epoxy cement. Older columns may be more difficult to attach, because of the unevenness of the bases, and because deterioration of the wood may have occurred. Some ingenuity will certainly be required.
  - 2) Once the Pillars have been securely attached to the bases, fill any gaps with plastic wood. If the holes are par-

ticularly large, build up the filler, allowing several days of drying between each coat. Plastic wood may appear to be completely dry but, if applied in thick coats, may shrink disasterously over a period of weeks.

- 3) Sand the Pillars, first with a rough, and then with a smooth paper.
- 4) Build the triangular capitals with their tetrahedronal tops. The triangles should be cut from one inch pine, while the tetrahedrons can be constructed from thin plywood or very heavy cardboard and paper tape. If plywood is used, the sharp edges should be filled with plastic wood or gesso modeling paste, and smoothed with files and sandpaper when thoroughly dry. The process may have to be repeated several times to produce a perfect tetrahedronal form.

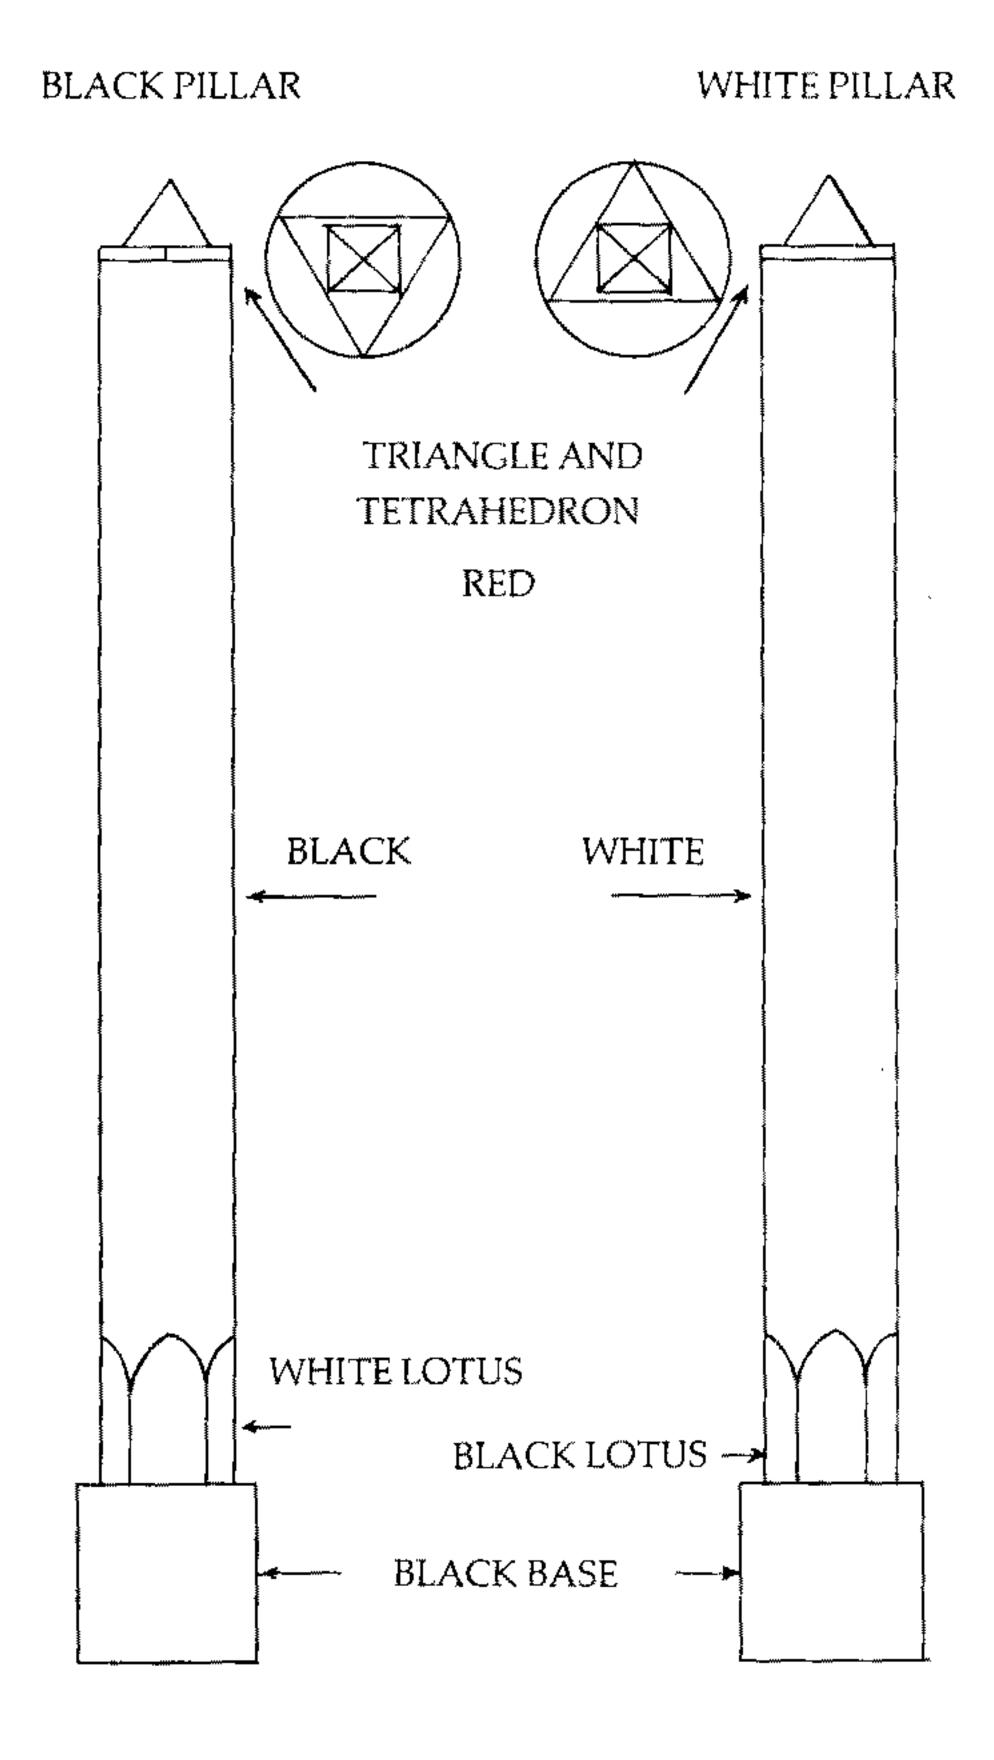

If desired, a small lightbulb can be incorporated into the capital, but care must be taken that there is no great build up of heat, which could present a fire hazard.

- 5) Coat the Pillars with a white priming paint.
- 6) Carefully measure, and draw the Lotuses at the bottom of each Pillar.
- 7) With enamel, paint one column black, and the other white.
- 8) Paint the Lotus flowers in the opposite color. Small brushes will be required for accurate outlines.
  - 9) Paint the bases black, and the capitals red.
- 10) Paint the hieroglyphic designs as given in the following pages, black on the white Pillar and white on the black Pillar.

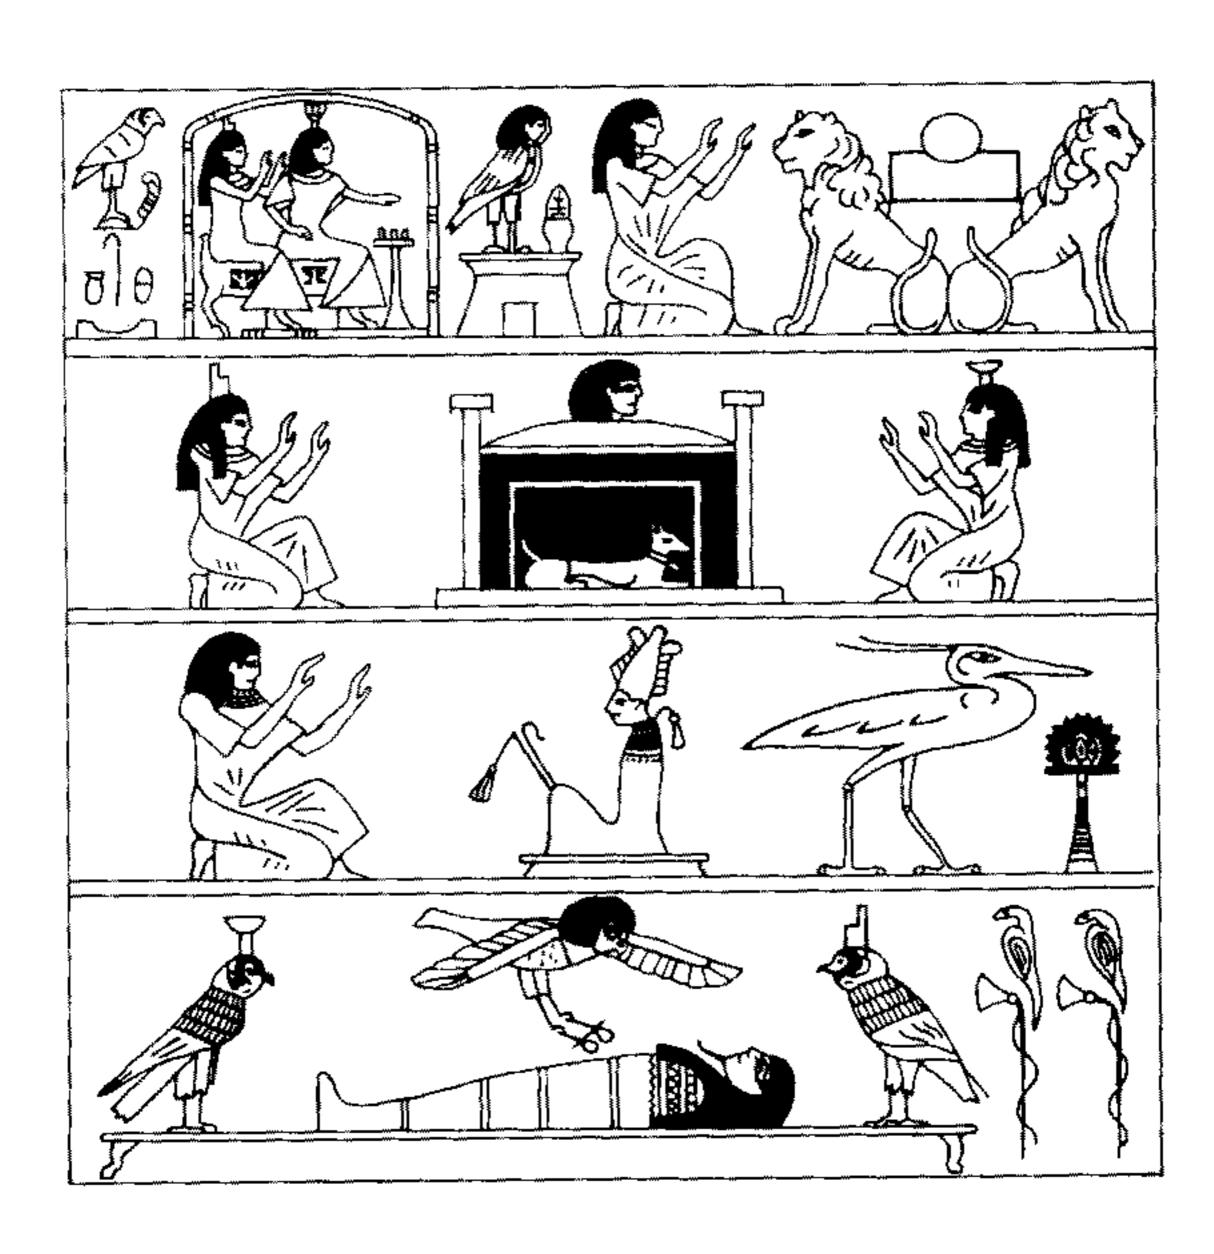

These are vignettes from the seventeenth chapter of the Book of The Dead, illustrations intended to accompany the "Hymn to the Rising Sun," slightly modified by the Order for use on the columns. The illustrations here are traced exactly from a paper written by Brodie Innes, entitled 0°-0° Grade of Neophyte Side Lecture No. 2A, Appendix to the Lecture on the Pillars (Carr P. Collins, Jr. Collection, the Bridwell Library, S.M.U., Dallas, Texas). The lecture mentioned was a brief one by Mathers who, with Brodie Innes, founded the A-0 after the collapse of the Golden Dawn Isis-Urania Temple in 1900.

These vignettes are very complicated, and few may choose to make the effort of painting them on the Temple Pil-

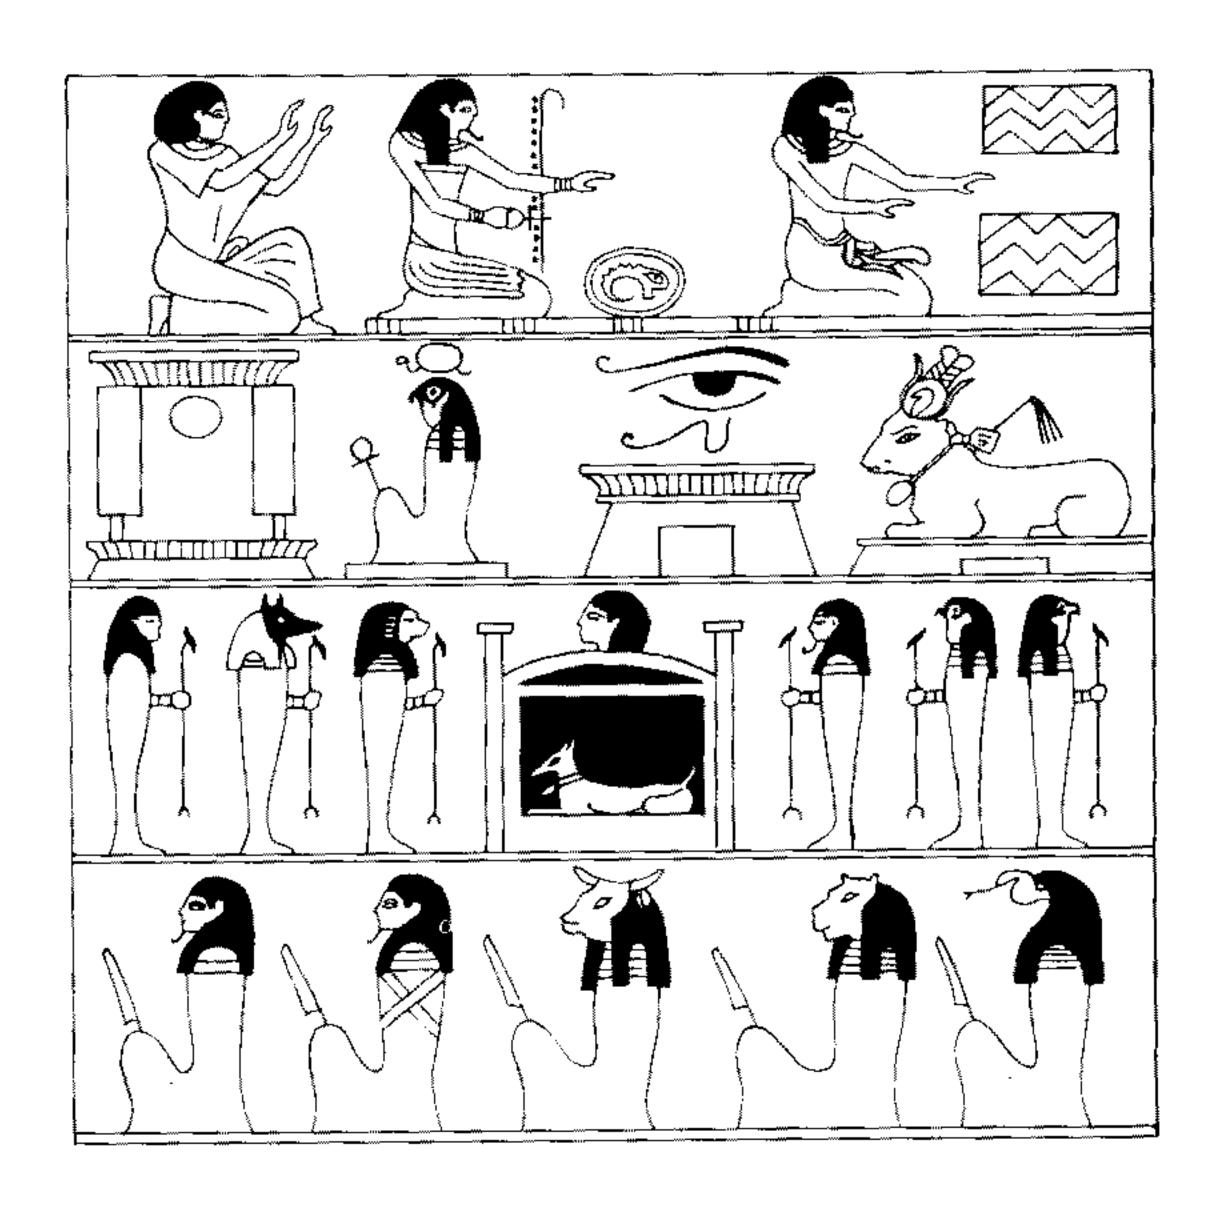

lars. They are included for the benefit of individuals or groups who are following the Golden Dawn methods down to the most careful detail.

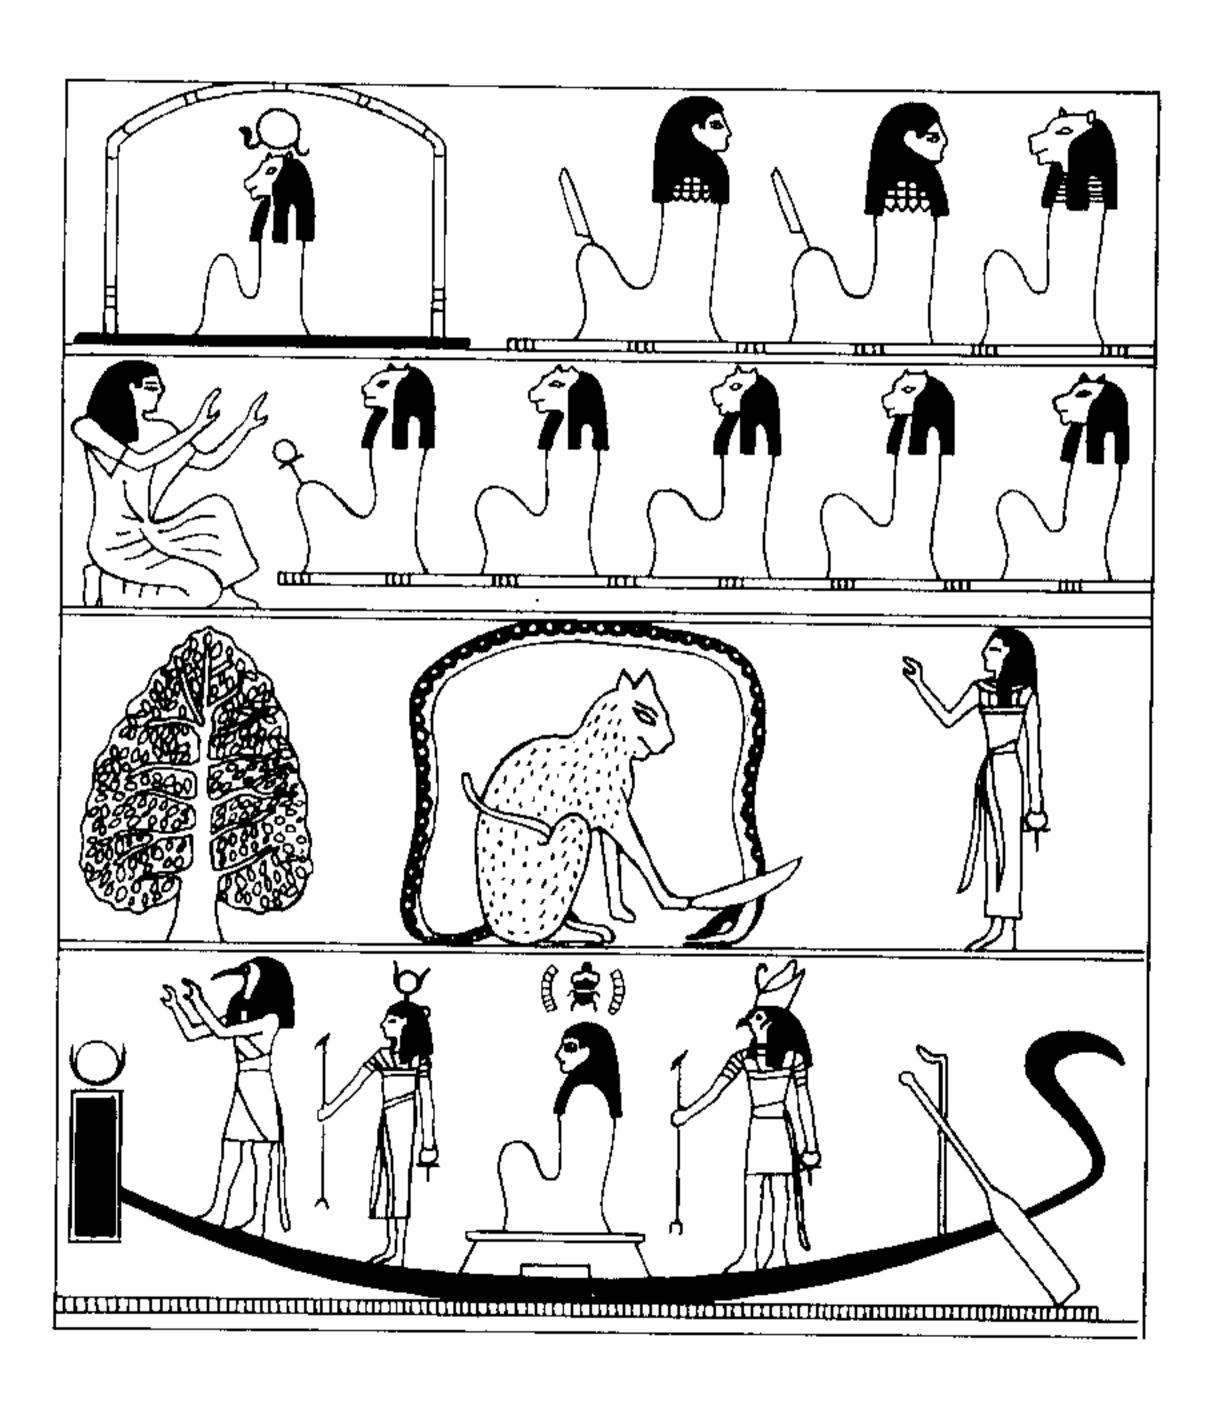

### WHITE COLUMN: UPPER SECTION OF EGYPTIAN SYMBOLS

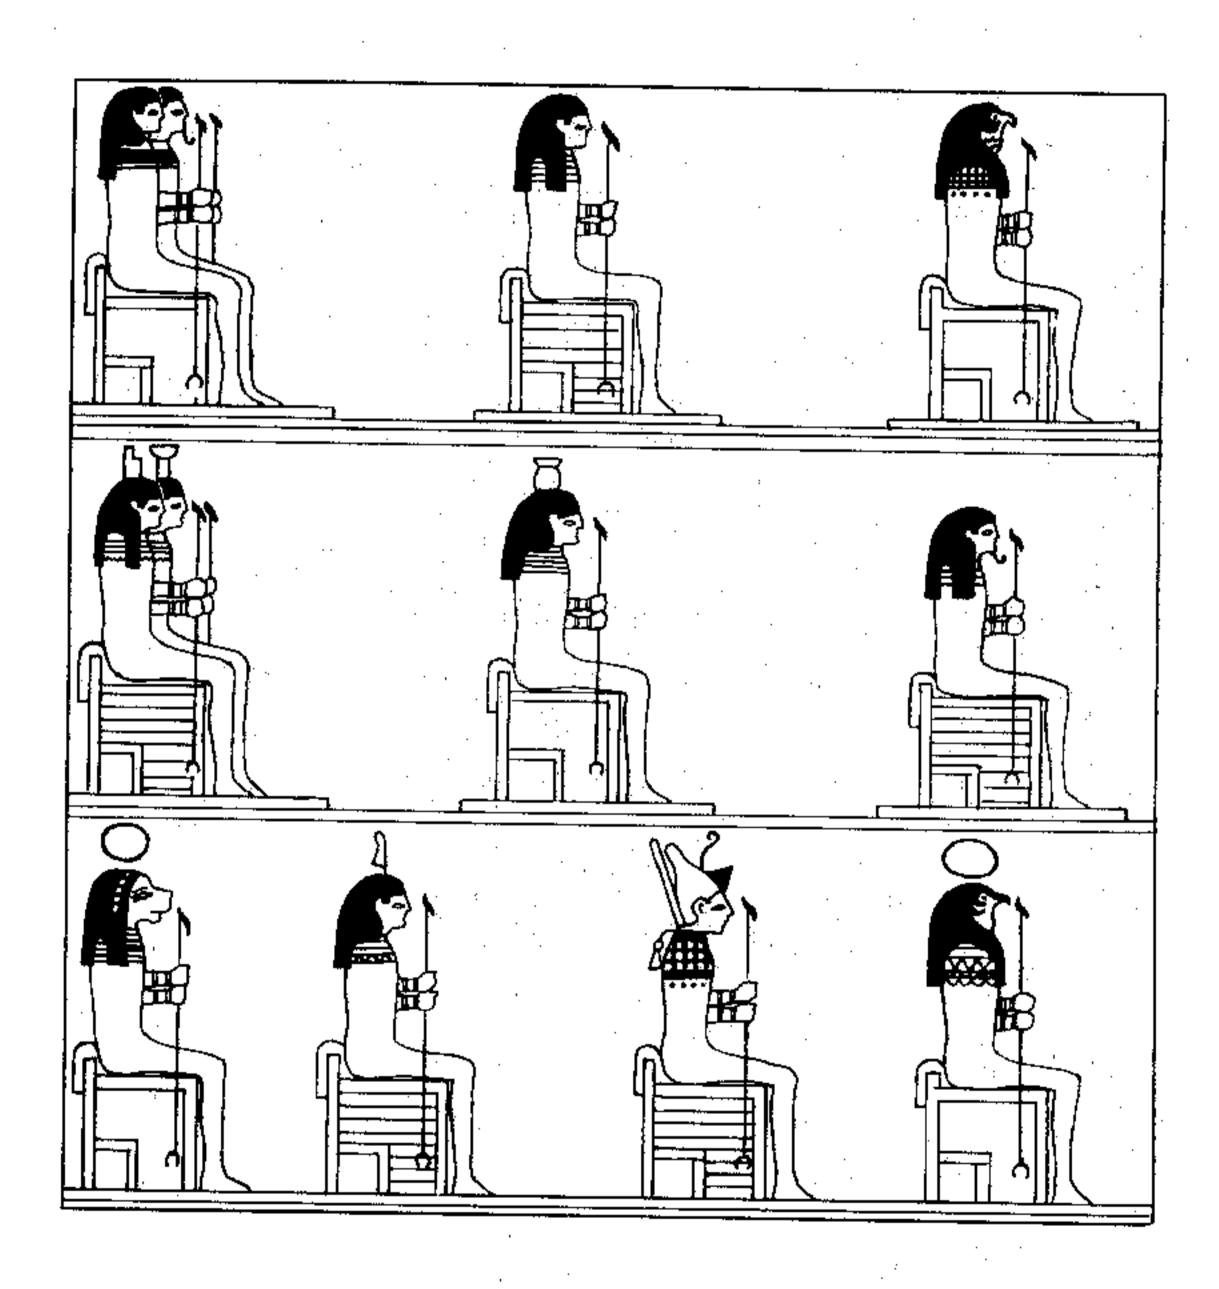

#### WHITE COLUMN: CENTRAL SECTION OF EGYPTIAN SYMBOLS

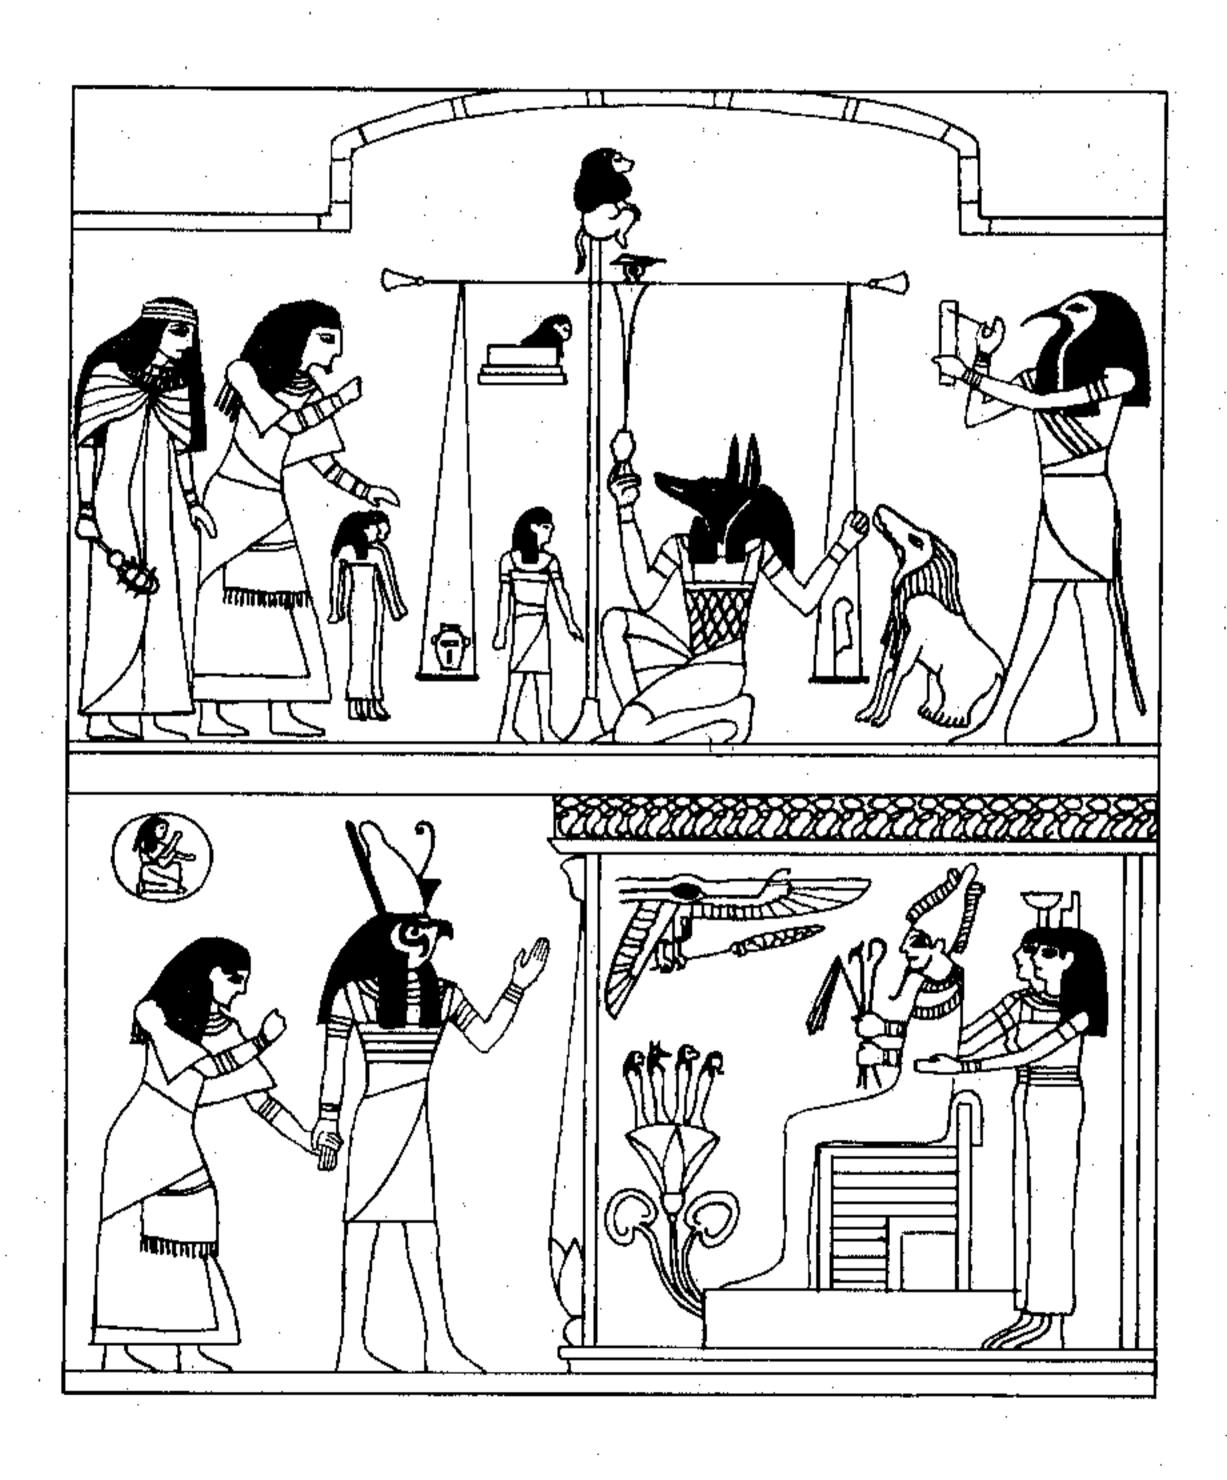

### WHITE COLUMN: LOWER SECTION OF EGYPTIAN SYMBOLS

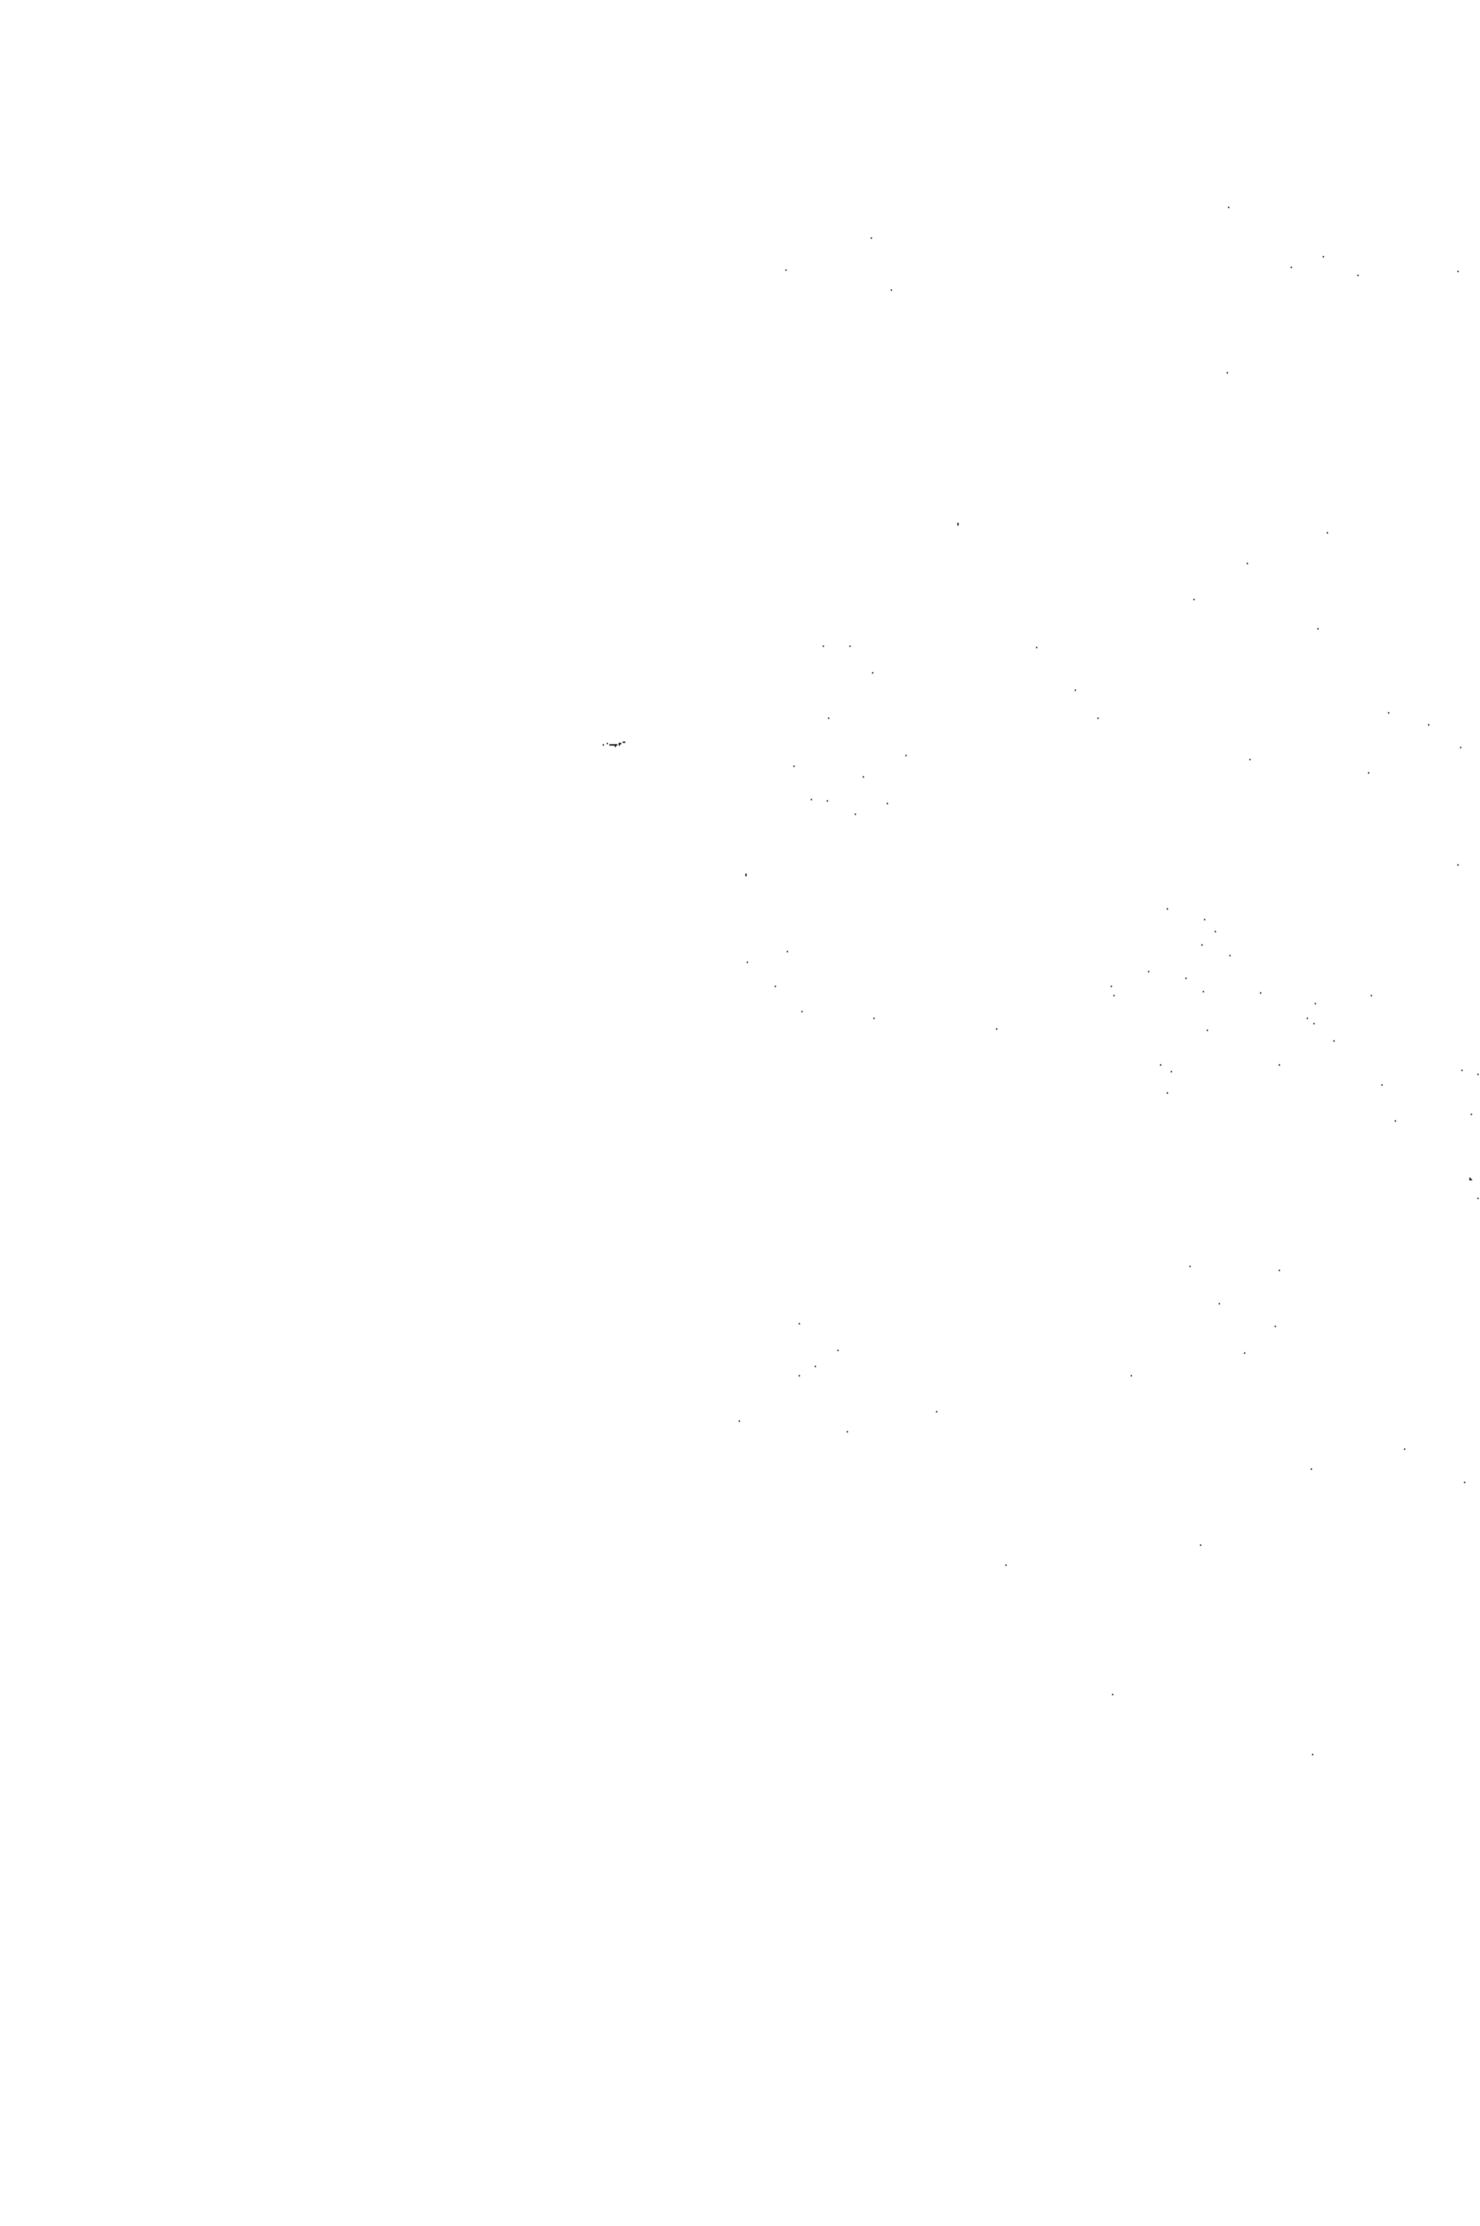

### BLACK COLUMN: UPPER SECTION OF EGYPTIAN SYMBOLS

### BLACK COLUMN: LOWER SECTION OF EGYPTIAN SYMBOLS

### 15 / The Temple Diagram

This diagram may be described as a complete "Ceremonial" Tree of Life. On each of the Sephira the appropriate God Names are painted in their opposite or *flashing* color, as is also found on the instruments. The principle of flashing colors is very basic to the Golden Dawn system. The Qabalah, of which the Tree of Life is the primary symbol, involves opposites, and the desire to bring those opposites into perfect balance. A force functions properly only when its opposite and balancing force is present. Thus the colors, which are the mundane aspects of the actual spiritual forces, are activated in the presence of their opposites.

The Sephiroth are painted in the colors of *Briah*, while the paths are painted in the colors of *Atziluth* providing a balance of masculine and feminine in the same symbol.

The following are the proper colors of the Sephiroth and Paths, the opposites of which can be easily derived from a color wheel, as has been previously noted. The full scales of color in the four worlds, as apparently developed by MacGregor Mathers, can be found in Regardie's *Golden Dawn*, and Crowley's 777.

### SEPHIROTH:

- 1. White brilliance
- 2. Grey
- 3. Black

#### THE SECRET TEMPLE / 74

- 4. Blue
- 5. Scarlet Red
- 6. Yellow (gold)
- 7. Emerald
- 8. Orange
- 9. Violet
- 10. Citrine, olive, russet and black

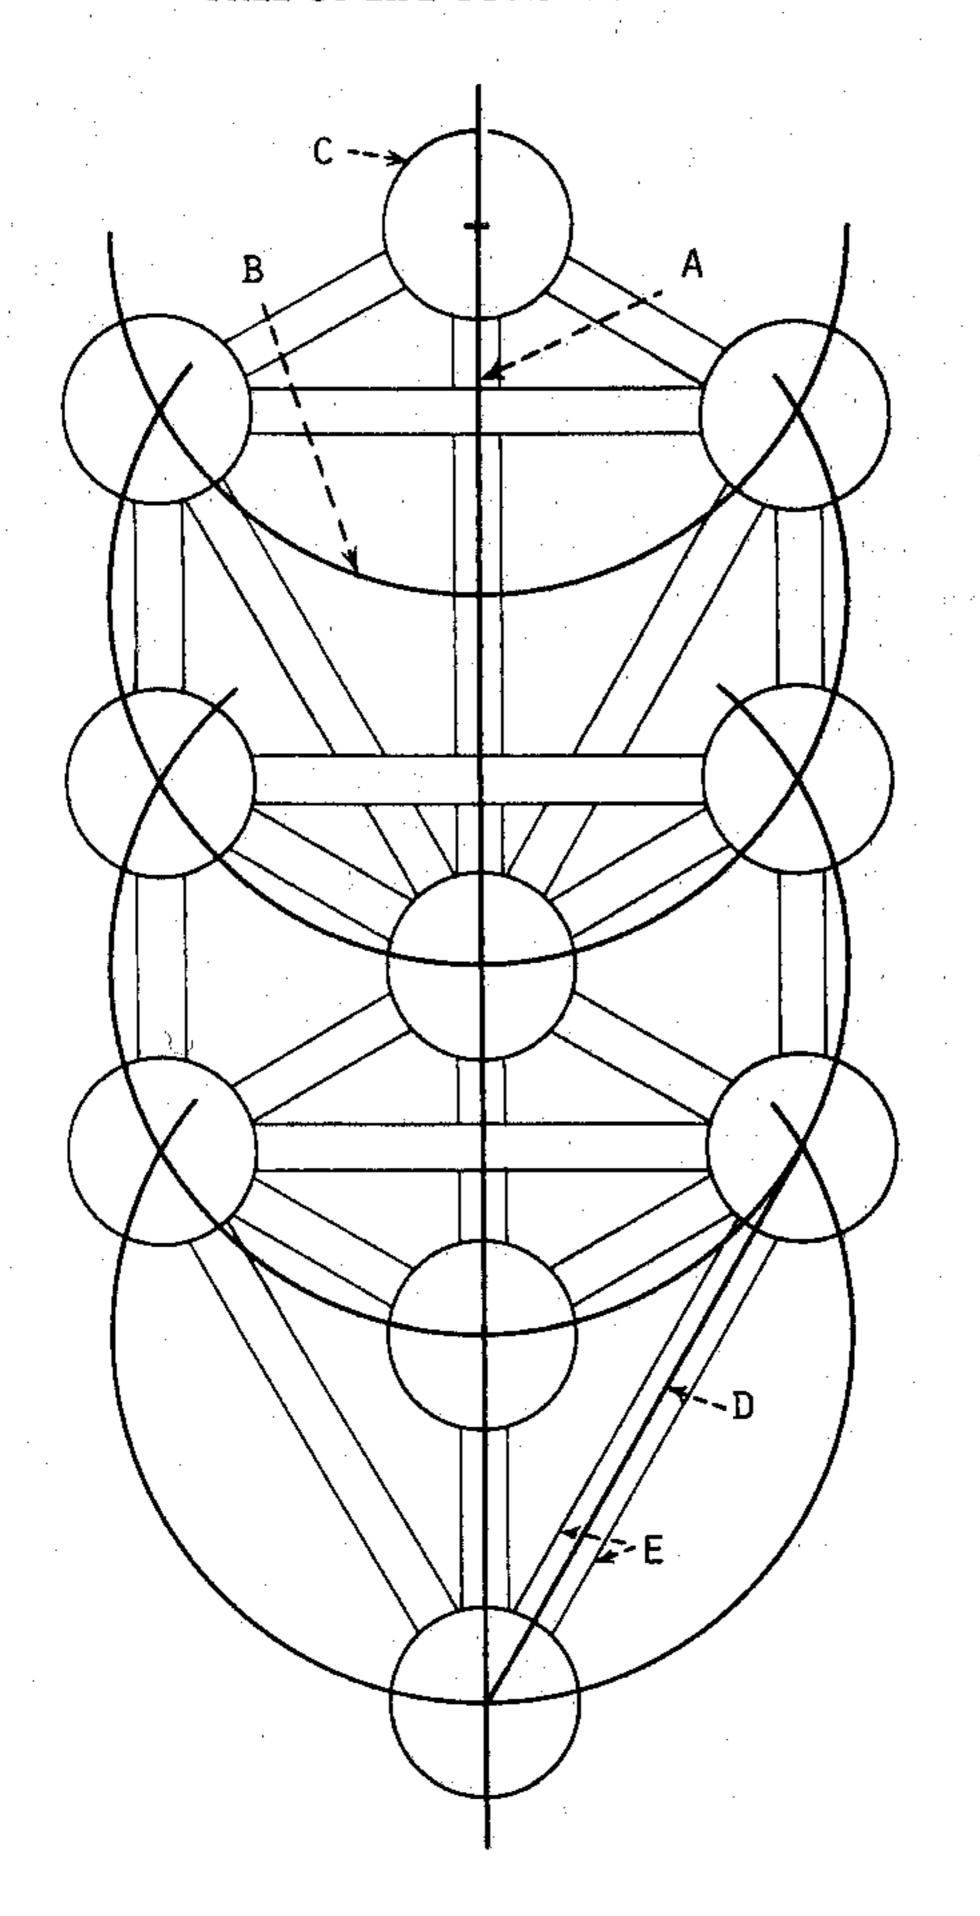

### PATHS:

- 11. Bright pale yellow
- 12. Yellow
- 13. Blue
- 14. Emerald Green
- 15. Scarlet
- 16. Red orange
- 17. Orange
- 18. Amber
- 19. Yellow, greenish
- 20. Green, yellowish
- 21. Violet
- 22. Emerald Green
- 23. Deep blue
- 24. Green blue
- 25. Blue
- 26. Indigo
- 27. Scarlet
- 28. Violet
- 29. Crimson (ultra-violet)
- 30. Orange
- 31. Glowing orange scarlet
- 32. Indigo

### Constructing the Diagram

- 1) From birch plywood of any thickness cut a panel to some standard size, such as  $9 \times 12$ ,  $11 \times 14$  or  $16 \times 20$ . Any size panel would suffice, but a standard size permits mounting in an inexpensive stock frame.
- 2) Seal the front and back of the panel with gesso. Allow to dry and sand lightly. Repeat the process with a second coat.

### TREE OF LIFE CONSTRUCTION

- 3) Using a pencil, ruler and compass, construct a Tree of Life. This is very simple, though a surprising number of even experienced students are unfamiliar with the method:
- A. As shown in the illustration following, measure from both sides of the panel, and draw a central line from top to bottom.
- B. Determine the length of the Tree on the basis of the space desired above and beneath it. Set the compass to a measure which is 1/4 the total intended length of the diagram. For example if the Tree is to be eight inches long, set the compass to two inches.

Set the point of the compass at the top of the line and draw a circle. Then bring the compass point to the area of intersection of the central line and circle just drawn. Repeat this procedure until there are four intersecting circles. This establishes the precise centers of the Sephiroth.

- C. Draw the Sephiroth with the compass. The proper diameter of each Sephira is one half the original compass line (B; if two inches, the diameter of the circle would be one inch).
- D. Draw Path lines between the center points of the Sephiroth.
- E. Using dividers or a ruler, establish the width of the Paths by measuring two points equidistant from the central line (D). Note that the width of the Paths must be such that five Paths will fit at the top of the sixth Sephira, Tiphareth. With a ruler, draw the outside line on each Path.
- 4) Paint the Sephiroth using artist's acrylics. Outlines are most easily established by using water-thinned paint in a compass.
- 5) Paint the Paths. Here, too, outlines can be established using a ruling pen and thinned paint. Since there are so many colors, and since retouching may be necessary, it is advisable to mix the paints in small bits of aluminum foil.

Try to paint all Paths requiring the same color at one time.

- 6) Add the Serpent, which touches each Path (see full-color Temple illustration).
- 7) Add the God Names, to the Sephiroth, and the Hebrew letters to the Paths.
  - 8) Allow the paint to cure, and varnish as usual.

# 16 / The Banners of the East and West

The Banners are a difficult craft project because of the sharp corners required on some pieces. Their preparation demands both sewing experience and a rather meticulous sense for detail.

Material for the Banners should be very thin. It is almost impossible to fold thick cottons or other fabrics into these patterns; they invariably appear lumpy and crude. The ideal fabric, from the standpoints of availability of colors, cost and ease of construction, are acetates intended as lining materials.

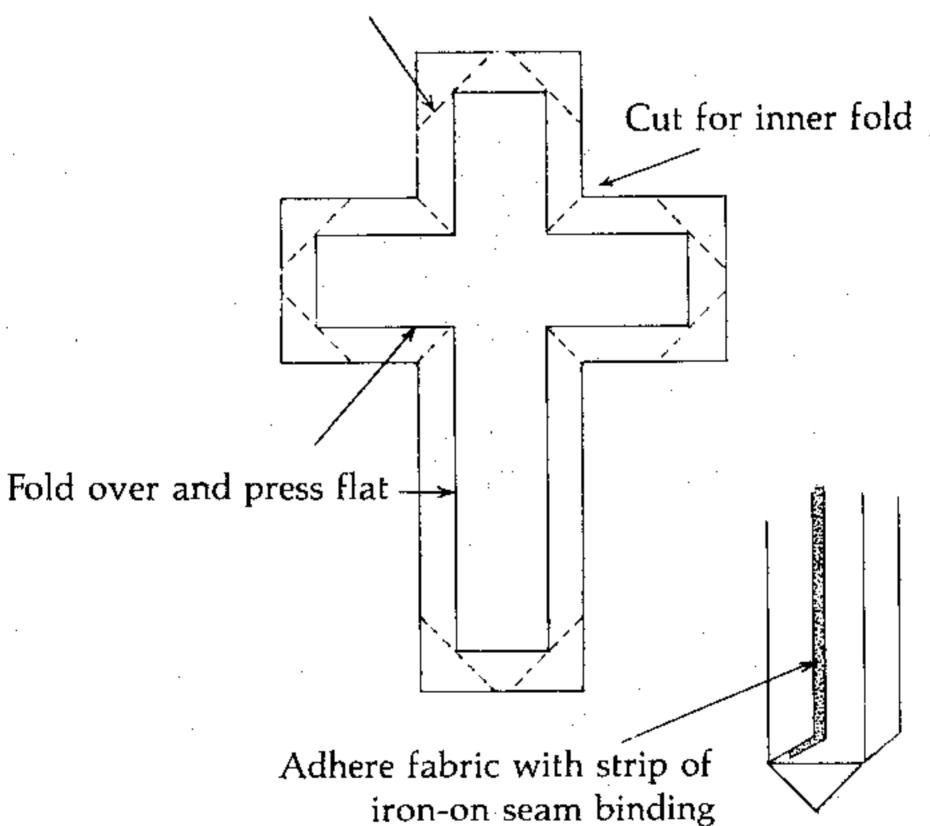

To some extent, this should be considered a "cut and paste" project. Iron-on seam binding should be used to hold the pieces firmly in place before they are overstitched. It is essential that the pieces be held completely flat before final sewing, if a machine is used. Otherwise fabrics may pull to one side or the other, creating uneven lines.

The following is a technique for sewing a cross. In the absence of iron-on seam binding, the panels should be basted (large temporary stitches) to the background panel.

- 1) Iron the fabric, and on the back of it draw a cross. A soft black pencil will generally show up, even on black fabrics. A white chalk pencil available at fabric stores may also be used. Lines must be measured carefully.
- 2) Cut around the outside of the Cross, leaving a border of approximately 3/8 inch.
- 3) Cut the corners and central angles as shown in the illustration.

- 4) Apply a very small drop of white glue at each inner or outer corner point. This will keep the fabric from fraying at the point where there is nothing to be folded over.
- 5) With a steam iron, fold back the edges of the cross. Some materials will hold such an edge easily, but others may require tacking with a small strip of the seam binding.
- 6) Place the cross on the background material, with strips of seam binding underneath. Cover it with a cloth and press with a hot iron.
- 7) Finally, overstitch around all of the edges, keeping the lines as straight as possible.

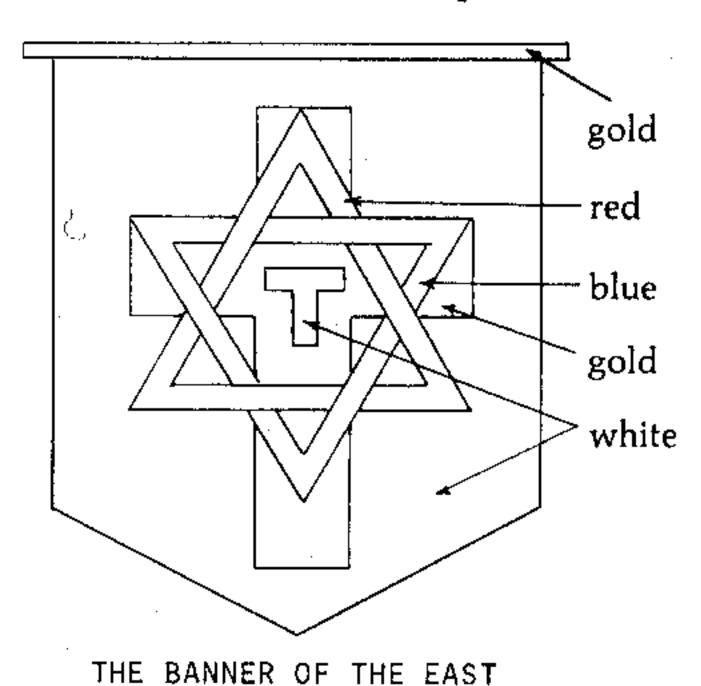

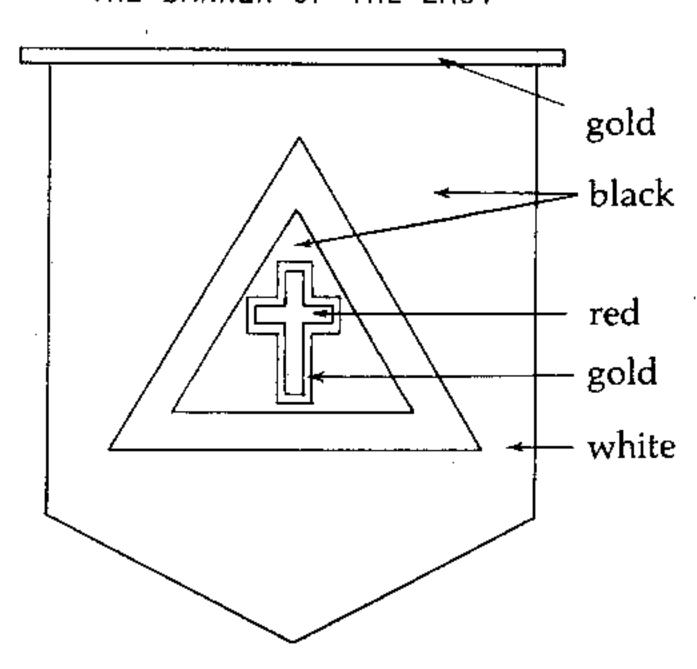

### Hanging the Banners

Both Banners have red tassels (available in most fabric stores) at the corners, and are hung from a gold bar. On the black Banner the bar is suspended from a black cord, and on the white Banner the cord is red. The simplest way to suspend the Banners is to attach them with heavy thread. In those illustrated, a metallic gold embroidery thread is used. The cross bars

here are nothing more than simple 3/4 inch dowel rods, with small wooden drawer pulls at the ends.

The Golden Dawn papers state merely that the stand for the Banner of the East should be white, and that of the Banner of the West black. Very simple stands can be made of round or square wood mounted on a base plate. The twisted columns of the stands illustrated here are a commercially available decorative dowel often used as curtain rods. The finials are actually curtain rod end pieces, and the bases are plywood circles sold ready-cut in many hardware and lumber stores. The Banner cord is suspended from another drawer pull.

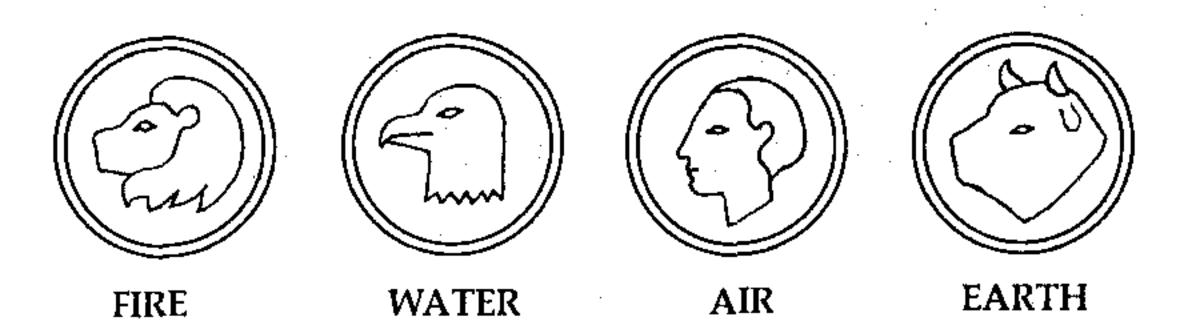

THE BANNER OF THE WEST

### 17 / The Enochian Tablets

These Tablets are placed at the four cardinal points around the Temple: The Air Tablet is in the east, the Water Tablet is in the west, the Fire Tablet is in the south and the Earth Tablet is in the North.

While these Tablets, or Watch Towers, are essential to a completely accurate Temple, particularly for group working, there are some simple alternatives. The first is the use of the Angelic Sigils above the Tablets. These can be painted on round pieces of wood and placed appropriately. A second alternative is the use of small plaques of the Kerubim, either painted or carved. The Lion is Fire, the Eagle is Water, the Man is Air and the Bull is Earth.

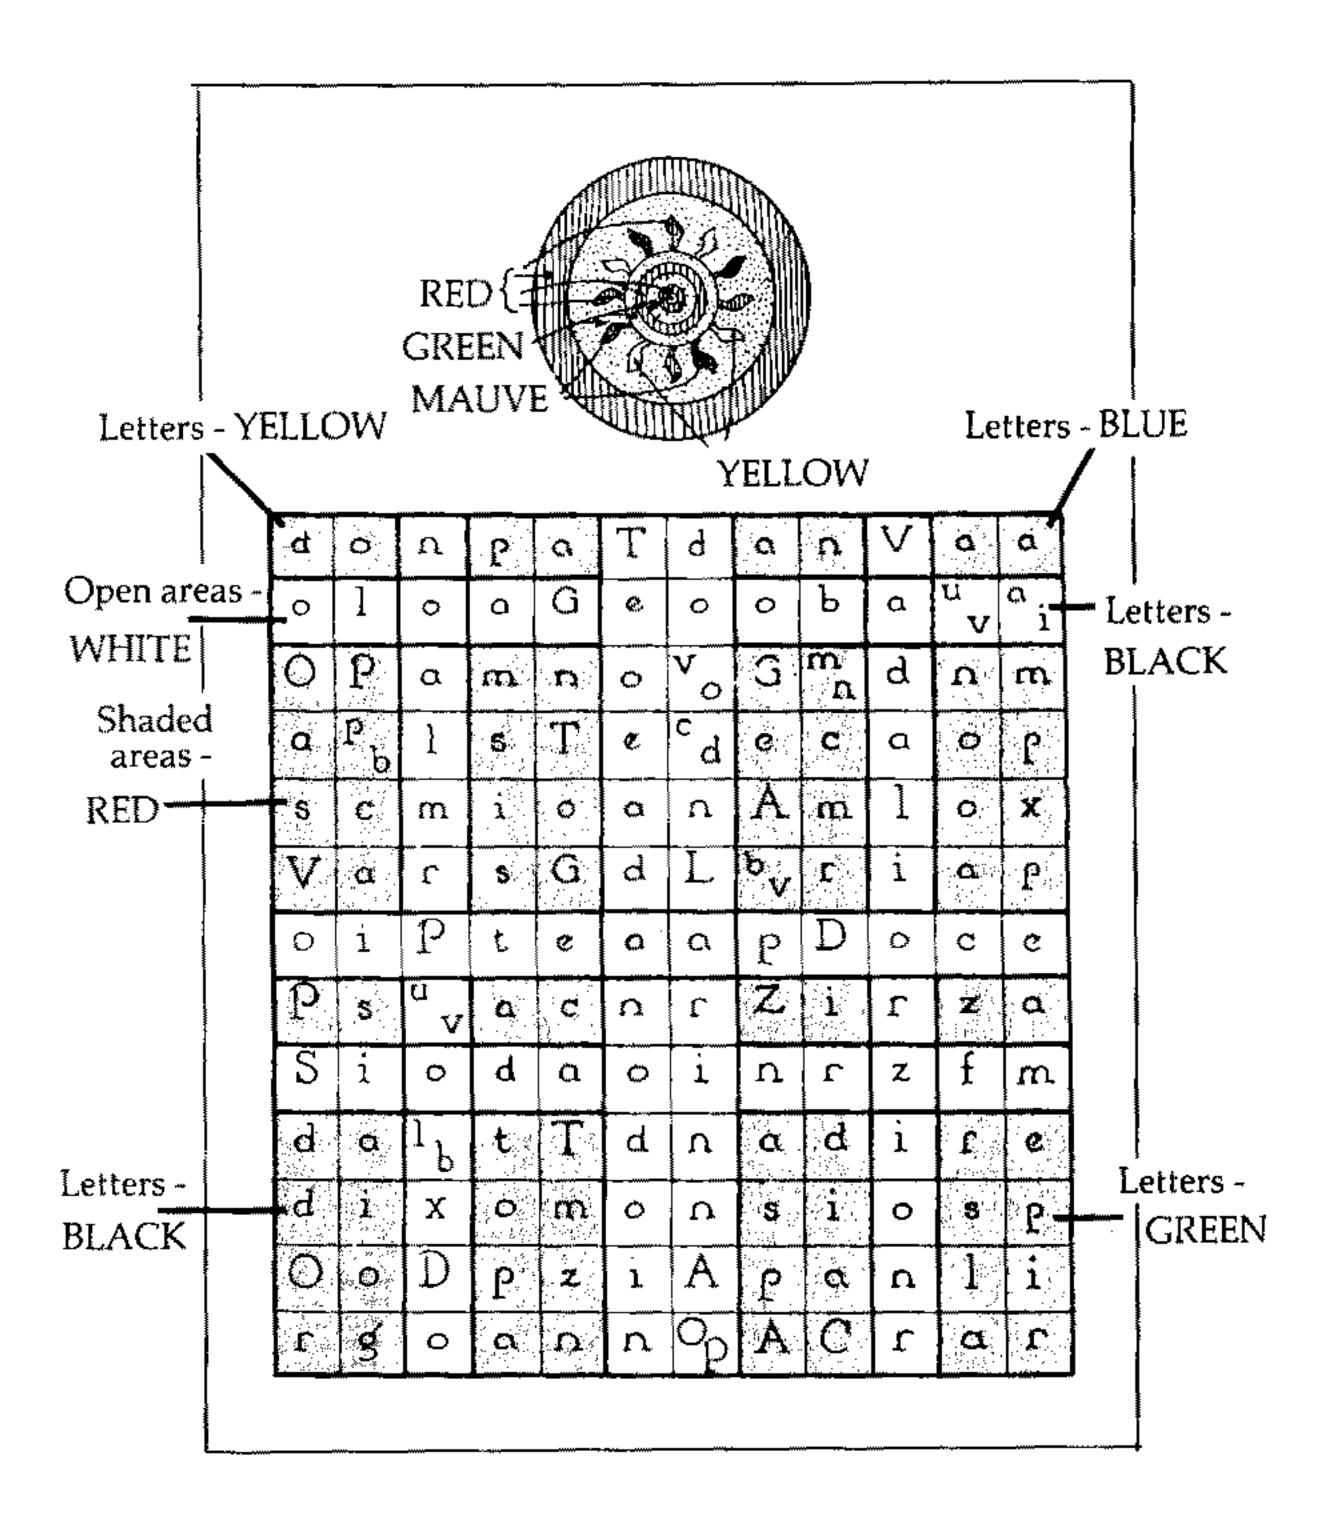

The painting of the Enochian Tablets is a very time-consuming task, but well worth the effort required. Their presence in the Temple adds extraordinary vitality.

- 1) Cut four pieces of birch plywood to approximately 16 x 20 inches. Size is less important than the proportions, since the Tablets themselves are square, but with the addition of the Sigils, the whole is a balanced rectangle.
- 2) Seal the boards, front and back, with gesso, and sand lightly.
- 3) Paint the background color of the board. The backgrounds of the boards should not all be painted at once. After an acrylic (or oil) paint has cured for some time, new paint will not properly adhere to it. And since work on the Tablets is invariably slow, it is best to complete one before beginning another.
- 4) Carefully measure the squares on the boards, and rule them out with a soft pencil.
- 5) Paint the lines with a fine brush or with thinned paint in a ruling pen.
- Paint the letters in the opposite color of the background.
- 7) Allow the paint to cure, and coat with clear acrylic varnish.
- 8) Attach picture hooks and wire to the back of the panel.

The Tablets shown in the color photograph of the Temple are arranged strictly for illustration purposes. Normally, the Air Tablet would be hung above the Altar diagram in the east. It should also be noted that these particular Tablets have the square section and the Sigils cut out and raised, which is a more interesting, though unneccessary option.

### 18 / Robes

On the basis of published descriptions, it would appear that the robes of the original Golden Dawn were extremely elaborate and beautiful. Their rituals must have been art forms in the highest sense of the word.

While a very complicated robe may be produced, the Golden Dawn papers describe one which is little more than a Tau cross. This is worn with a *Nemyss*, an ancient Egyptian form of headgear.

The basic robe of the *Adeptus Minor* is of white material edged with gold. That illustrated here is of a light polyester fabric, with stock gold trim. A hood has been substituted for a Nemyss.

This book will not attempt to give sewing instructions on robes, in the belief that those who already sew will not need such assistance, and others are likely to hand the project over to a competent tailer or seamstress.

Whatever the design or construction of the Robe, it is a most important part of the ritual apparatus. As anyone who follows these practices will attest, the wearing of a robe effects a psychological separation from normal life. The more special the robe, the more pronounced this effect is likely to be.

.

### Notes on Consecration

Rituals of consecration for each of the instruments is given in *The Golden Dawn*, Volume Three. These are composite rituals, involving the use of the Pentagrams and Hexagrams, which should be studied very thoroughly before they are actually performed. The rituals presuppose familiarity with all Banishing rituals. Moreover, a student is advised to spend some time working with the exercise of the *Middle Pillar*, which will confer no small appreciation of the energies invoked in these ceremonies.

While it is not explicitly stated in the Golden Dawn documents, some consideration should be given to the astrological aspects under which the instruments are consecrated.

A ritual of consecration may be done repeatedly, thus adding to the potency of the instruments, and increasing understanding of the nature of consecration in general. These Golden Dawn rituals seem to have been developed, partially, as an attempt to teach the methods of invocation. They are unsurpassed in that regard.

Finally, it should be noted that instruments are consecrated through their repeated use.

## the Secret Temple

This extraordinary new book (by the author of *Introduction to the Golden Dawn Tarot*) contains all that is required to produce a symbolically accurate temple and a full set of magical instruments in the Golden Dawn tradition. Full color photographs of the temple and of the instruments, as well as the precise hieroglyphs of the pillars, appear here in print for the first time. Instructions are given for the construction of the altar, pillars, Enochian tablets, Rose Cross Lamen, wands, etc., the difficult sigils and inscriptions having been worked out completely by the author. *The Secret Temple* is highly recommended to students of the Golden Dawn, Crowley, and the practical Qabalah.

#### Special Note to the Reader

At the request of the publisher, the author has removed all footnotes and endnotes from the book and placed them onto this book's dedicated website:

#### www.newscienceofheaven.com

The notes contains a great deal of additional supplementary material and information of potential interest to readers, and are not just bare references. They are therefore recommended by the author to readers wishing for further information.

The website also contains a large number of illustrations and photographs that could not fit into the book, including photos of many of the heroic scientists who battled against herd thinking and blind prejudice over the past century and a half to found and develop plasma physics as a discipline, and those who are still struggling to extend its boundaries.

#### How to Use this eBook

Look out for linked text (which is in blue) throughout the ebook that you can select to help you navigate between notes and main text.

You can double tap images to increase their size. To return to the original view, just tap the cross in the top left-hand corner of the screen.

#### Acknowledgements

I wish to acknowledge the remarkable and unswerving support of my editor, Mark Booth, who believed in this book from the beginning. Having recently retired from publishing, Mark is now lost to all the other authors who might have benefited from him as I have. I can only regret that the armies of worthy authors to come will not be able to have his firm but friendly guidance towards that ultimate end: making the book work. We authors can only repay him with our words. And these are mine.

I must thank as always my wife Olivia for her continual and devoted involvement in this book, reading it, making suggestions, expressing doubts when necessary and giving encouragement when doubts would be misplaced. I have never written a book without her help, and never more so than with this one.

I wish to thank also my very dear friend of many years, Chandra Wickramasinghe, for his vision and encouragement in exploring this exciting area of science and for co-authoring the astrophysical paper reproduced in the Appendix.

But if there be a fifth nature, such as is introduced by Aristotle, this is the essence of gods and souls –

Marcus Tullius Cicero, *Tusculan Disputations*, Book I (Anonymous translation of 1715)

#### The Discovery of the Clouds

In October 2019 a momentous event took place, but as sometimes happens in these cases, no one noticed at the time. This event could have consequences for humankind's view of its place in the Universe for what remains of human civilization. It could entirely change the 'job description' of Planet Earth. It means that the Earth–Moon system is significantly different than we thought it was. And it may well change everything.

So why did nobody draw the obvious conclusions? People did eventually notice the discovery, for the findings came to be widely reported as a news item, as may be seen from googling the subject. And there appears to have been an unchallenged acceptance of the existence of what was reported. But still there is a lack of any grasp of what it means. No one seems particularly concerned about it. It has been one of those news items that is exciting for a day and then forgotten, as new stories appear and 'the news caravan moves on'. The implications of this anomaly remain unnoticed, and the strange fact's potential to lead to great things is apparently unsuspected.

History often works in this way. Who could have known that a failed and penniless artist in Vienna could end up starting the Second World War? Who could have predicted that a spoiled six-year-old rich boy, who had continual temper tantrums and pounded the floor screaming insanely that his parents must obey him, would end up calling himself Lenin and creating the Soviet Union? Who could have predicted that a New York property developer who likes gold doors and had no political background would become the American President?

But what happened in October 2019 was not political. It was far more important than that.

What happened was that some astronomers saw something.

I happen to have a roving eye for anomalies; I am always on the lookout for things that don't fit with present scientific understanding. And so, in October 2019, I noticed that something anomalous had been observed by three Hungarian observational astronomers (who actually looked through optical telescopes, as so many astronomers today rarely do).

In fact, what they observed had first been seen by a Polish astronomer named Kazimierz Kordylewski in 1961. Kordylewski claimed to have seen a strange cloud at a particular location in the night sky, and he worked out that there must be two of them, another at a corresponding location in relation to the Earth and Moon. (See <u>Figure 1</u>.) So these soon became known as 'the Kordylewski Clouds'. However, no one else could see them, and that, everyone presumed, was that.

Fifty-eight years went by and then the Hungarian astronomers, to their great joy, observed the same cloud that Kordylewski had seen. Because it is extremely fine and emits no light it is extremely difficult to see, but they studied it as closely as they could.<sup>2</sup> It was at the exact location that Kordylewski had indicated.

This is a cloud between the Earth and the Moon, though not in a direct line of sight. It is very high above the atmosphere of the Earth and several times larger than our planet.

I was fortunate to spot the paper that the Hungarians published summarizing their research. I contacted the lead astronomer of the Hungarian team through the website <a href="www.researchgate.net">www.researchgate.net</a>, on which I am listed as she is, and asked whether they had considered any of the plasma aspects of the cloud? The answer was that they were studying the cloud 'only from celestial mechanics point of view, not from plasma perspective'.

Plasma is what this book is about. To put it very simply, plasma is matter that is made of 'incomplete or partial atoms', known as ions, and the much smaller particles known as protons and electrons. Plasma has sometimes been called the fourth state of matter, after solid, liquid and gas, but finer even than gas. We call the physical matter that is familiar to us 'atomic matter' because it is made of whole atoms, whereas plasma can also be described as non-atomic or subatomic matter.

Plasma is very familiar to us even though we may not realize it, for the Sun is entirely composed of plasma, and the stars are plasma too. Plasma also manifests itself in lightning, including ball lightning and other mysterious phenomena we will examine later. But plasma is otherwise and for the most part invisible, and we will be going into that unseen aspect of plasma a great deal as we go along.

As someone who keeps a keen eye on what is happening in plasma research, I realized that I must publish something quickly to alert people to the true significance of this cloud, since the Hungarians were not dealing with the plasma aspect.

I phoned my friend Professor Chandra Wickramasinghe, who as a retired Professor of Astrophysics is an expert on all such things, and told him about the cloud and asked if he would co-author an article for a scientific journal discussing the Kordylewski Clouds' importance from the plasma perspective. We then wrote an article together, which was published in the journal *Advances in Astrophysics* in November 2019.<sup>3</sup> It is reprinted at the end of this book as an appendix.

The fact that the Earth–Moon system contains two giant clouds that together are nine times the size of the Earth means that we might be more accurate in describing it as the two-cloud system, with the Earth and a moon thrown in. These two clouds are made of plasma.

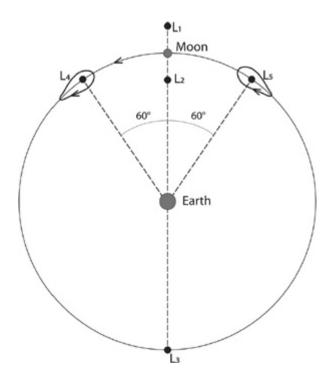

FIGURE 1. This diagram shows the locations of the 'Lagrange Points' known as L4 and L5 of the Earth–Moon system, indicating the positions of the two clouds. In this diagram, the Earth is at the centre, and the Moon is directly above it. Although distinct, bounded balls of plasma can form anywhere at modest scales (as for instance, and as we shortly see, the tiny balls of ball lightning on the Earth), for really big ones in space it is helpful for them to come to rest in spaces free of gravitational pulls, and when such a niche appears it is pretty certain that it will soon be filled by plasma which will form a ball as big as the niche allows. And that is why the L4 and L5 points are perfect homes for huge plasma clouds, for they are the only two points between the Earth and the Moon free of gravitational pull from either the Earth or the Moon. This image is not drawn to scale and the relative sizes of the bodies shown here bear no relation to their true sizes; this image is intended solely to show the geometrical spatial configuration. Seen at this scale, the Earth and the Moon would be extremely tiny or perhaps even too small to see, and as the main text explains, each of the Clouds is four and a half times the size of the Earth. (Image drawn for the author by Eric Wright)

This matters because, as I will show, there are good reasons to believe that plasma, with its ordering properties, can in certain circumstances be in some sense alive and can evolve intelligence. Because plasma is made up of charged subatomic particles, it is volatile and displays a tendency to form complex, constantly evolving patterns. This is particularly true of discrete bundles of plasma that we will call plasmoids, such as the Kordylewski Clouds. (What a plasmoid is will be explained fully later.)

Though this may surprise or even shock many readers, who may find this implausible on the face of it, I will also show that nearly all scientists in the

field believe that the Universe is more than 99 per cent made of plasma – although this too has not yet filtered down to the general reading public.

And if the Kordylewski plasma clouds are examples of an inorganic life that has existed for billions of years, they may, as I hope to show, have had a role in forming this planet throughout its long cosmic history. They may even have helped create organic life. Clearly these ideas taken together open up vast new and very fruitful areas for speculation on the origins of the cosmos and the role of intelligence within it.

In fact, I will be arguing that life in its basic state is inorganic, and is not made out of atomic matter. I suggest that it is made out of pre-atomic matter, namely the atomic particles, electrons and protons, and ions — plasma. Thus, I am suggesting that we and all living things in the Universe, whether organic or inorganic, arise from this plasma, and that the organic state is secondary to our fundamental nature as plasma beings. I believe that we can now start to articulate 'a new science of heaven'. That is what this book is about, and that is what I propose to do.

I will also show that as well as being very new, these ideas are also in another sense very old; ancient religions and philosophers in the classical world including Aristotle formulated very similar ones. They might not have been able to apply mathematical measurement to assess the levels of complexity necessary for life and intelligence that modern physicists can now apply, but a shift in perspective caused by the new physics of plasma will cause us to reassess many ways of understanding the world previously dismissed as discredited or even cranky.

I will not enter into theological discussions and will confine myself to the new science, with the exception of a brief historical review in Chapter 6 of some early religious texts that have relevance to our subject. I believe that much of what we have previously called spiritual is really plasma, and that it exists all around us and in us. Many spiritual experiences reported throughout human history are really encounters with plasma phenomena or plasma entities. What does this mean for religions? I believe it leaves them all untouched. My primary purpose is to reconcile the 'spiritual' with the 'material', and thereby to show that the dispute between them is false. There is in fact no contradiction between them when one digests the teachings of the New Science.

# Exploring the Nature of Plasma Clouds and their Energy

I first got to know Professor Chandra Wickramasinghe in the 1970s along with his colleague, mentor and former teacher, Sir Fred Hoyle. It is appropriate that this should be the case, because Fred Hoyle was famous not only for being one of the world's leading astrophysicists and theoretical astronomers, but for writing the science fiction classic *The Black Cloud*, which is about an intelligent cloud in space. I will refer to that book again later.

The Kordylewski Clouds are not clouds in the usual sense of being made of water vapour and being within our atmosphere. There are two of them, as we have seen, roughly centred round two precise points in space between the Earth and the Moon.

What kind of clouds could possibly exist at these points? After all, they are in what we used to call 'outer space', so what could be there to make a cloud?

The clouds are composed not only of the subatomic particles already mentioned, but also of dust particles. That may not sound very exciting, but that is because you may well not yet know how important, complex, and incredible a dust cloud in space is.

Space dust is described thus in a 2008 technical paper:

Dust is a generic name for minute solid particles with diameters less than 0.1 to 0.5 mm. The use of a range [of size] rather than a specific number for the cut-off indicates that this upper limit for dust size is somewhat arbitrary and scientifically insignificant. A plausible argument for the range is that particles greater than these sizes are unlikely to float in the air by themselves ... There is also a somewhat arbitrary lower limit of a few nanometres to distinguish dust grains from more fundamental particles, such as electrons, protons ... Therefore, this choice of the 'lower' limit includes small clusters as dust.<sup>1</sup>

It is useful to read this, but it is not entirely satisfactory for us, because it speaks of dust floating in air, and there is no air in space. However, it can act as a kind of approximate guideline for us about sizes of dust particles, whether single or clustered. Astrophysicists also sometimes like to speak of dust in space as 'grains'. And although much dust is spherical, in space much of it is elongated and hence grain-shaped. Also, there is a lot of lumpy, clumpy and irregular dust in space.

Not all dust contains atoms, but that will have to be explained later, when I tell how plasma makes its own dust of itself. Plasma is essentially made up of two subatomic particles: electrons that have a negative charge, and protons that have a positive charge and ions ('incomplete atoms'), which also have a positive charge. In whole atoms there is a balance between the negative and positive charges. 'Physical matter' is really atomic matter, because in order to be 'physical' it has to be made of whole atoms.

However, an atom can be turned into an ion by the simple means of stripping it of one of its electrons. It is important to realize that ions are not considered to be physical matter and that they are charged.<sup>2</sup> And to give some idea of the relative sizes, it is usual for a charged dust particle to have 10,000 electrons sticking to its surface. Because protons are larger than electrons, they do not stick to dust particles in quite so high numbers.

Contrary to what we might assume, living as we do in a material world, particles only very rarely come together to form whole atoms, and non-atomic plasma is the main constituent of the Universe – more than 99 per cent of it. As I say, we will see shortly why scientists think this, but the important point here is that from this perspective atomic matter is exceptional, and hard, rocky planets are very rare indeed.

It is because there is more plasma than there is atomic matter that I view ions, protons, and electrons as primary, and whole atoms as secondary. This way of looking at things will, I hope, become clearer as we go along.

We will see later that our Sun spews out huge quantities of positively charged protons and ions and fills the whole solar system with them. So our entire solar system, including the Kordylewski Clouds, is constantly being inundated with a never-ending flood of ions and protons.

Since space is full of furiously racing and whizzing particles, of both negative and positive charge, it is not possible for a dust cloud to exist

without each single dust particle within it being massively bombarded with thousands of subatomic particles (which as we have seen are much, much smaller than the dust particles) and thus becoming charged itself. It is well known by all scientists working in this field that the surfaces of dust particles (or 'grains') are continuously being charged by a relentless rain of thousands of electrons and positive ions striking them. When those are equal in number and the positive and negative charges balance out, the dust particle is said to have a 'net zero charge'.

However, this is a rare event, and even when it occurs it is likely to be transient and exist for only a few instants. In our own solar system the Kordylewski Clouds are exposed to this relentless and never-ending hurricane of positive charge coming from the Sun in the form of the solar wind. The Sun also emits some filaments or streams of negatively charged electrons as well, but they are far less important components of the solar wind than the positively charged ions and protons. There are such things as negatively charged ions, and they can exist within a plasma, but they are not important for our discussions in this book, and we will not refer to them again.

One might well ask, if there are sustained streams of positively charged particles being emitted by the Sun, why does the phenomenon not have a name in the way that streams of negatively charged particles (known as electrons) are called electricity? It was Peter Mitchell (1920–1992), a very dear friend of mine, who took steps to fill this gap in our language, naming such flows of positive currents proticity. Peter won the Nobel Prize for Chemistry in 1978. He even built a mechanical motor that operated on proticity! He called it a protic motor, and he built it to show that proticity could be a source of energy to drive a motor sitting in front of you in the same way as electricity can do.

So I shall use the word proticity from time to time to describe the flows of positively charged currents, even though the word is still used only rarely by others. Because Peter worked in a highly specialized and closed branch of bio-energetics, not enough people ever knew of his terminological innovation for it to spread to the wider public. Peter is so little known to the general public that his obituary (which I wrote) is included here as Appendix 2. (My efforts to locate Peter's protic motor in recent years have

drawn a blank, alas. I just hope it is still preserved somewhere, though if so, it is possible that no one knows what it is.)

Because the Kordylewski Clouds and others like them are bombarded from without by charged particles, the particles inside them and the dust interact with great intensity and complexity, evolving, as we shall see later, highly complex patterns. Such a large charged dust cloud in space is known as a 'dusty complex plasma'.

One of the things which distinguishes such an entity is that all the processes inside it cannot be described by physicists using simple linear equations. Everything taking place inside this kind of plasma operates in a manner described by non-linear equations.

When something is linear, it means there is a direct and identifiable connection between cause and effect, so that one can predict behaviour. But when linearity breaks down, everything becomes unpredictable and immensely complex.

It is important to bear non-linearity in mind, because it is a feature of quantum mechanical super computers now in development, and analogy with these will play a part in arguments later in the book to show that these clouds may be highly intelligent.

Quantum computers break their information down into a different kind of bit, now called 'qubits'. (The 'qu' stands for 'quantum'.) Because quantum theory is a bit weird, a qubit can have the values of 0 and 1 at the same time. Very much like 'having our cake and eating it'. Some say that qubits can even have any value between 0 and 1.

Meanwhile, the more restless and thrusting of the computer developers look upon qubits as being 'so yesterday'. They now say the future lies not with qubits but with 'qudits'. A qudit can have ten or more values at once.<sup>3</sup> This is like having ten cakes and eating them.

One might say that the work being done today on quantum computers is an attempt to construct computing devices that can do 'non-linear reasoning'. Direct causation is linear. But some circumstances allow all sorts of unpredictable outcomes and unexpected influences. Direct causes that might take place in an ideal world get interrupted and blocked, and things come at you from the left and the right and they change things. This, as we will see later, is the inescapable and fundamental non-linearity of dusty complex plasmas.

One useful definition of dusty complex plasma in a single sentence is by physicist Osamu Ishihara:

Complex plasma, also known as a dusty plasma, is a plasma with micron-sized (a micron is a millionth of a metre) dust particles in which charged dust particles interact with a background plasma.<sup>4</sup>

This definition dates from 2008, and things have moved on since then, and the people working in the field now just say 'dusty complex plasma'. Also, it is no longer necessarily seen to be the case that the charged dust particles and the 'background plasma' should be viewed as separate things that 'interact'. It is probably more accurate to view the dusty complex plasma as a unified entity, which happens to contain not only those two components or states, but many more besides. I will be elaborating on this last point as we move along in the discussion. And it is also not the case that the dust particles must be micron-sized. They can be much smaller than that, namely nano-sized (one billionth of a metre).

It is surprising how many scientists, including distinguished professors and experts, still do not understand what is a dusty complex plasma. Science has fragmented so much that they do not even know what the people down the hall in the next lab are doing.

There are some developments that tend to make research into plasma better known. Very fine plasmas are used to deposit circuits onto microchips, so there are large numbers of people working for the huge corporations making these semiconductor chips. And one of their greatest concerns is the various types of plasma. Indeed, there are huge profits to be made by getting a new and useful angle on this subject. Many new developments are therefore understandably subject to close corporate secrecy. In addition to these corporate considerations, the military and security people are hard at work on plasma, and they do not shout from the rooftops either.

The number of advanced plasma scientists who do openly publish new findings, and are free to do so, is very small. When one of them dies, such as Padma Kant Shukla (1950–2013), all of his colleagues in the field feel as if a whole wing of a mansion has been closed down, such was the vastness

of his knowledge, and such is the sense of loss of both himself and of his wisdom and experience.

We will see later that heroic free thinkers and researchers have suffered from the attempts of the Nazis, the Soviet military and security complex, the CIA and others to control their work.

## A Brief History of Plasma Research

If plasma research is little known even in many academic and scientific circles, it is pretty much unknown to general readers. In fact, many of the greatest and most brilliant scientists of the age have been involved in researching the area, including several Nobel Prize winners. I am proud to have counted some of them as my good friends, to have corresponded with them and discussed their ideas.

This book includes a historical view of plasma research. I have written it partly because its implications for our understanding of extraterrestrial intelligence and indeed our own intelligence are astonishing.

I will start with a brief account of how the terminology of plasma evolved, and this chapter will also introduce some of the eccentric personalities, mind-blowing ideas and amazing discoveries that feature later in the book.

In 1879, Sir William Crookes (1832–1919), an English scientist, discovered in his laboratory in London something strange, which he called 'the fourth state of matter'.

Crookes was a chemist as well as a physicist; he discovered the element thallium, for which he is also famous. In 1895, he identified the first known sample of helium. But it was the discovery by Crookes of what he called 'radiant matter', which we now call plasma, that changed the whole of physics and chemistry. He had been studying cathode rays, which are rays of electrons. He established that they travelled in straight lines, that they could cause fluorescence, and generate heat in a Crookes tube [the vacuum tube, or valve, which was first invented by him]. He had opened the door and let in subatomic particles.<sup>1</sup>

I have Crookes's first published report of it in front of me as I write, since I own an original copy of the *Proceedings of the Royal Society of London* for 1879–80, which contains it. It is on page 469, and it is entitled 'On a Fourth State of Matter'. Perhaps it is worth my quoting one of Crookes's astounding concluding remarks in that paper, which I believe has never been reprinted until now:

These considerations lead to another and curious speculation. The [general view is that the] molecule – intangible, invisible, and hard to be conceived – is the only true matter, and that which we call matter is nothing more than the effect upon our senses of the movements of molecules, or, as John Stuart Mill expresses it, 'a permanent possibility of sensation'. [But in Crookes's view] the space covered by the motion of molecules has no more right to be called matter than the air traversed by a rifle bullet can be called lead. From this point of view, then, matter is but a mode of motion; at the absolute zero of temperature the inter-molecular movement would stop.

This statement of 1879 certainly gives us something to think about at the subatomic level, and it can readily be seen also that Crookes was anticipating the phenomena later to be known as superconductivity (<a href="here">here</a>) and superfluidity (<a href="here">here</a>), phenomena we will return to when we come to consider quantum mechanical qualities in plasma that may help give rise to intelligence.

The great genius Nikola Tesla (1856–1943), who invented alternating current and thus likewise played a huge part in bringing about the existence of the modern world through making it possible for everyone to have electricity, describes frankly in his autobiography that he only decided to study electricity and commence his electrical inventions, such as the Tesla Coil, because of inspiration from Crookes.

In his 1919 account of his life, Tesla wrote:

Two or three months before I was in London in company with my late friend, Sir William Crookes, when spiritualism was discussed, and I was under the full sway of these thoughts. I might not have paid attention to other men, but was susceptible to his arguments as it was *his epochal work on radiant matter* [my italics], which I had read as a student, that made me embrace the electrical career.<sup>2</sup>

Later in life, Crookes became so interested in the possible existence of a 'spirit world' that he attempted to apply scientific techniques to psychical research. He became something of a hero to the general public of Victorian and Edwardian England for his boldness in that, but many scientific

colleagues pulled their longest faces and accused him of losing his senses and betraying science. However, as we shall see in Chapter 6 when we consider plasma and matters spiritual, Crookes's intuition may have been well ahead of his time and may have been amply justified.

Today we call matter in this fourth state 'plasma', the name given to it by the American scientist Irving Langmuir (1881–1957), who would win the Nobel Prize for Chemistry in 1932.

He coined the word because the way a charged gas carries electrons and ions reminded him of the way blood carries red and white corpuscles, so the plasma seemed to him to be 'alive'. His historic introduction of 'plasma' as a new word in physical science appeared in print for the very first time – together with the word 'sheaths' for the 'skins' of plasmas – in an article entitled 'Oscillations in Ionized Gases', which was published in August of 1928 in a scientific journal, where he wrote these memorable words:

The word 'plasma' will be used to designate that portion of an arc-type discharge in which the densities of ions and electrons are high but substantially equal. It embraces the whole space not occupied by 'sheaths' 3

It was then that the science of plasma physics was truly born; all the work that had been done since 1879 on what had been called 'ionized gases' or 'radiant matter' became known retrospectively as plasma research.

- 1941: Lyman Spitzer (1914–1997) suggested that interstellar dust particles might be acquiring charge from electrons in the form of 'ionized gas' (Spitzer's preferred name for plasma, 'ionized gas' was, as we have just seen, later abandoned). We now know that all interstellar dust is probably charged. But in 1941, this was an astonishing new idea.
- 1954: the Swedish scientist Hannes Alfvén (1908–1995) suggested that planets and comets in our solar system might have been formed as the result of the coagulation of dust particles in the solar nebula that had been charged by plasma. He won the Nobel Prize for Physics in 1970.
- 1955: Winston Harper Bostick (1916–1991) created the first artificial plasmoid (blob of plasma) in his laboratory.

- 1955: Peter [Pytor] Leonidovich Kapitsa (1894–1984) suggested that ball lightning was really a spherical plasmoid, a type of plasma. Between 1930 and 1934 he was the first Director of the Mond Laboratory at Cambridge.
- 1958: Eugene Newman Parker proposed the existence of a 'solar wind'. This proposal was first made by Peter A. Sturrock, with whom I carried on a correspondence on other subjects many years ago, and James Hartle. We now know the solar wind to be two different kinds of plasma wind emanating from the Sun. One is called 'the slow solar wind', which travels at speeds below 450 km s-1 and the other is called 'the fast solar wind', which travels at speeds of between 700 and 800 km s-1. But because the Sun is rotating clockwise, the beams do not go straight, they swirl with the rotation and form an Archimedean spiral shape in space, and hence swish across us rather than blasting straight at us, as illustrated in Figure 2.

Inherent in them is a powerful magnetic field. The Ulysses spacecraft, launched towards the Sun in 1990, detected and thus confirmed the existence of these separate solar wind components in 1994/5. The space between the Earth and the Sun is completely filled with solar wind plasma. But prior to 1958, the 'establishment scientific opinion' said that 'outer space is empty' and was composed solely of vacuum.

• 1958: the Van Allen Radiation Belts – two doughnut-shaped belts made of plasma surrounding the Earth – were discovered, which we now know to be made of plasma: these will be considered in Chapter 4, (here).

Also in 1958, the United States exploded a ten megaton atomic bomb in the high atmosphere (at 75 kilometres, or 46.6 miles) in order to produce an artificial aurora and study the plasma regions above the planet. (The follow-up studies were still going on a year later, so lasting was the damage to the high atmosphere.) Many more such atomic blasts followed. It is now believed that all of these atomic explosions, apparently about one hundred of them, and other crazily ill-advised military 'tinkering' with the high atmosphere by

both sides in the Cold War, contributed to the instabilities of worldwide climate that we see today.

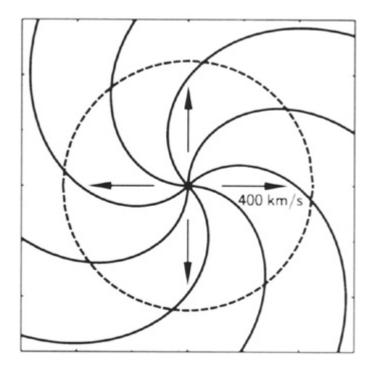

Figure 2. The central dark spot is the Sun. The dotted line is the orbit of the Earth, intentionally simplified here to look like a circle. The solar wind is not blasting straight at us, but is swirling in this way, with the swirls sweeping across us. This drawing is taken from Alexander Piel's excellent book *Plasma Physics* (2nd edition, Springer Verlag, Heidelberg, 2010). He does not give his source for it, and the speed has been indicated wrongly by the unknown artist, nor is the rotation taken into account for the speed indication. But the basic idea is clear, namely the Archimedean spiral form of the solar wind which fills our solar system.

- 1959: my friend Thomas Gold (1920–2004) coined the term 'magnetosphere' to describe a tear-shaped region of magnetized plasma surrounding the planet, which protects it from harmful aspects of the Sun's solar winds. Tommy also conducted important research on the Universe's continuous creation of matter, an important area of study that is very relevant to complex dusty plasmas, as we will see later.
- 1960: Theodore G. Northrop and Edward Teller (1908–2003) provided the theoretical explanation for the existence of the Van Allen Belts.

- 1961: in the Soviet Union David Albertovich Frank-Kamenetsky (aka Frank-Kemenetskii, but also mistakenly aka Kamenezki or Kamientsky) (1910–1970), suggested in an article for a technical journal that plasma may exist within living organisms. He thus anticipated much of the subject of the latter part of this book.
- 1962: Chandra Wickramasinghe, while still a PhD student of Sir Fred Hoyle (1915–2001) at Cambridge University, proposed that the dust known to exist in interstellar and inter-galactic space, until then thought to be ice grains, was really made of carbon. This entirely revolutionary idea important to this book, because as we have seen, complex dusty plasmas contain such dust was accepted by the astronomical community five years later.
- 1963: David Pines laid the foundations for quantum plasma physics and collective behaviour in 'solid-state plasmas' by his studies of 'the properties of electron plasma oscillations in high-density low-temperature quantum plasmas', in other words, the wobbles that happen in plasmas at extremely low temperatures. This may sound very obscure and technical, but we will see later that it was fundamental to the advance of plasma physics, including with regard to plasma's capacity for bringing some of the weirder quantum phenomena into the macro world.

At the same time, my friend Peter Mitchell (1920–1992) published his full 'chemiosmotic theory' explaining that the energy functions of biological systems are based upon subatomic currents. This explanation came to be known as 'vectorial metabolism', because it describes the directions in space of energy usage within the body. In 1972, Peter introduced the term proticity, as already mentioned. He was awarded the Nobel Prize for Chemistry in 1978.

• 1982: Jay Hill and Devamitta Asoka Mendis suggested that the 'spokes' (so called by astronomers because they resemble the spokes of a wheel) found in the rings of Saturn the previous year by Voyager 2 consist of dust that has been charged in a plasma.

- 1986: Hiroyuki Ikezi predicted that plasma could exist as crystals. He called them 'Coulomb Crystals', named after Charles-Augustin de Coulomb (1736–1806), a pioneer of studies of electricity. He said these crystals could be formed by dust particles in a plasma. This is one of the key discoveries concerning the subject of this book, because crystals can play a vital role in storing information in ways necessary for the evolution of intelligence and for communication. As we will see later, it would be seven years before Ikezi's prediction was proved to be correct.
- 1989: Gary S. Selwyn and his team at IBM published his discovery that plasma actually manufactured dust, and that the dust found inside fusion reactors and other sources was not dirt or contamination, as had been assumed, but was created by the plasma itself.<sup>5</sup> In his dramatic experimental discovery, Selwyn was able to show by laser light scattering that, starting from single molecules, dust grew naturally from nanometre sizes up to micrometre sizes within the plasma.

This changed the whole of the science of plasma research. Until then plasma dust had been viewed as 'dirt', and how to avoid the 'contamination' by the dust or dirt was the focus of research attention. But once it had been demonstrated by Selwyn that plasma made its own dust, everything changed, and it was at this point that it became possible to envisage what we now call dusty complex plasma as a unique and very special type of plasma.

• 1993: Hubertus M. Thomas and Gregor Eugen Morfill announced at a plasma conference that they had discovered that the plasma crystals predicted in 1986 by Ikezi do really exist. In 1994 they published their research. At about the same time two other teams published papers making the same claim, one by Jiun-Haw Chu and Lin I, and the other by Yasuki Hayashi and K. Tachibana. As I will explain later on, dusty complex plasmas tend to contain plasma crystals, but it was only in 1993 that it became possible for scientists to make this assumption with confidence, to begin searching for them in earnest, and to include the crystals in their models of the complex interior structures of the plasmas.

• 1997: Jesper Schou, Philip Scherrer, and their team at Stanford University discovered gigantic plasma rivers flowing beneath the photosphere (commonly called the 'surface') of the Sun. A NASA press release from the Goddard Space Flight Center at Greenbelt, Maryland (Release 97-184, dated 28 August 1997) announced the discovery of "jet streams" or "rivers" of hot, electrically charged gas called plasma flowing beneath the surface of the Sun'. The press release quoted Jesper Schou: 'Moreover, in what is a completely new discovery, we have found a jet-like flow near the poles. This flow is totally inside the Sun. It is completely unexpected, and cannot be seen at the surface.'

Schou's colleague Philip Scherrer was quoted as saying:

These polar streams are on a small scale, compared to the whole Sun, but they are still immense compared to atmospheric jet streams on the Earth. Ringing the Sun at about 75 degrees latitude, they consist of flattened oval regions about 17,000 miles across where material moves about 10 per cent (about 80 mph) faster than its surroundings. Although these are the smallest structures yet observed inside the Sun, each is still large enough to engulf two Earths.

Schou and Scherrer also discovered that these rivers of plasma extend at least 12,000 miles below the Sun's 'surface' (i.e., the photosphere). Even more extraordinary, Schou and another colleague, Alexander G. Kosovichev (known as 'Sasha'), also discovered six additional plasma belts flowing beneath the 'surface', each of which is more than 40,000 miles across. If you add the widths of these flowing plasma regions together, they come to 257,000 miles total width of flowing plasma streams beneath the Sun's 'surface'. Just to put this number in perspective, it is greater than the average distance of the Earth from the Moon, which is 238,855 miles. (The orbit is not a perfect circle, hence the 'average'.) This discovery showed that dusty complex plasmas can contain fantastically intricate internal structures consisting of gaseous, liquid, and solid crystal plasma components, and that the crystals can liquefy and the liquids can crystallize.

Dust and dusty plasmas are ubiquitous in nature, occurring in interplanetary and interstellar clouds, dust rings around planets like Saturn, on the surface of the moon, noctilucent clouds [night-shining]

clouds] in the mesosphere [the third layer of the atmosphere, just above the stratosphere], or thunder clouds.<sup>6</sup>

The ways in which charged dust forms 'self-organized systems' in plasma is key to this book. But because dust can be so varied, we might well ask if we need special kinds of dust in order to have self-organization take place, or will any old dust do? On this point there has been a surprising recent discovery, announced on 28 November 2019 in *Nature*. It was a news story about a paper just published in *Physical Review Letters*, whereby some scientists at Northwestern University in America had shown that 'tiny plastic beads wandering aimlessly through water can spontaneously form organized swarms and clusters – just like swimming bacteria.' The polystyrene spheres 'artificially replicate bacterial swarming'.

This was accomplished by putting the microspheres in oil and subjecting them to pulses from an electric field. As a result of this, the spheres became electrically charged and began 'to suddenly spin and propel themselves through the fluid'. By altering the pulses, the spheres were made to cluster together into large clumps. After this, by shortening the pulses, the result was 'the formation of one continuous, roiling swarm of beads', which resembled the swarming of bacteria.<sup>7</sup>

When confronted by this kind of behaviour in inanimate particles, simply as a result of the influence of electrical fields, one realizes that what seems to be 'informed behaviour' or 'self-directed behaviour' can manifest without life in the conventional sense even being present, much less in charge. This is a rather sobering realization. If the same behaviour exhibited by bacteria can also be seen in inanimate plastic spheres, then what does this really mean? At a fundamental level, we see here with the lifelike behaviour of inanimate particles so precisely mimicking living things that even the very definition of 'life' is threatened.

We need to keep uppermost in our minds that the question 'What is life?' is not going to go away, and we will need to bring it to bear when we consider the question of whether or not plasmas can be said to be living, intelligent and conscious.

The phenomenon of the patterned clustering of micro-particles is fundamental in dusty complex plasmas. When it happens, the clumps are known either as 'Coulomb Balls' (once again, named after the scientist Coulomb, as with the earlier case), or as Yukawa Balls. The latter are named after Hideki Yukawa (1907–1981), the Japanese Nobel laureate physicist.

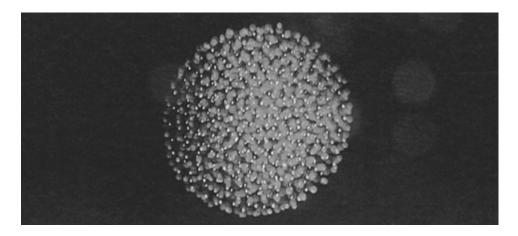

Figure 3. A Yukawa Ball, which consists of several hundred dust particles clustered together. The ball, which is a 'strongly coupled' (a term for describing elements of a system, such as particles, which have powerful interaction energies holding them together) dusty complex plasma structure, is approximately 7 mm across. The spherical cluster has a nested shell structure and is not just random inside. These balls are self-assembled. Such Yukawa Balls can form even at room temperature and do not need to have an exotic environment of very high or very low temperatures.

From Torben Ott, et al., 'Molecular Dynamics Simulation of Strongly Correlated Dusty Plasmas', 2010.8

Turning back to the question of where the dust comes from, in addition to the discovery that plasma manufactures its own dust, in 2017 Hamish Gordon and his collaborators revealed that the atmosphere also manufactures its own 'new particles' spontaneously from gas within the air itself. The new particles are nano-sized and they form in clouds in the Earth's atmosphere from condensable vapours.<sup>9</sup>

The authors of this report in the *Journal of Geophysical Research* state: 'New Particle formation has been estimated to produce around half of cloud-forming particles in the present-day atmosphere.' They define new particle formation as 'the process by which gas molecules collide and stick together to form atmospheric aerosol particles [particles floating in the air]. Aerosols act as seeds for cloud droplets ...'

A paper later in the same year by Robert Wagner and his collaborators, which included Gordon, reported further: 'The formation of secondary

particles in the atmosphere accounts for more than half of global cloud condensation nuclei.'

They went on to say that their experiments at CERN revealed that the formation of these particles was aided by ions in a positively charged plasma:

Our results indicate that ions enhance the nucleation process [the formation of nuclei around which particles can grow] when the charge is necessary to stabilize newly formed clusters. <sup>10</sup>

In the autumn of 2018, a further paper appeared on this subject by Dominik Stolzenburg, Paul M. Winkler and their collaborators. <sup>11</sup> They said:

Nucleation and growth of aerosol particles from atmospheric vapors constitutes a major source of global cloud nuclei ...

And further work on this subject was published in *Nature* in October of 2019, when Christina J. Williamson and her collaborators reported crucial new findings about the subject. <sup>12</sup> This team of researchers has discovered that new particle formation in the atmosphere 'persists at all longitudes as a global-scale band in the tropical upper troposphere, covering about 40 per cent of Earth's surface.' They say that global climate models do not take account of this and the existing climate models 'underestimate both the magnitude of tropical tropospheric NPF [new particle formation] and the subsequent growth of new particles to CCN [cloud condensation nuclei] sizes.' Accordingly, all public climate change discussions at the moment are deeply flawed because they rely upon inaccurate models.

This team says: 'New particles form in the atmosphere when condensing gases form stable clusters with diameters of more than 15 nm [nanometres] or so.' They then say that these particles are too small for detection by satellites, which are unable to detect particles smaller than 100 nm. That is why this important phenomenon has been missed, because it is so difficult to detect by our existing technology. As a result of these new findings, NASA has recently set up a programme to try to obtain more detailed information about these new particles in the atmosphere, so that we can know how they affect our climate models and, of course, our climate itself.

The formation of these tiny particles out of 'nothing' in our atmosphere is very similar to the formation of tiny particles out of 'nothing' in plasma,

as both are a result of clustering processes within the two separate media of plasma and air. And both processes are quite recent discoveries: the plasma processes have been known for several years now, though not widely so, and as we have just seen, the atmospheric processes are an even newer revelation. The similarities of 'appearing to get something out of nothing' in both plasma and in air suggests that a universal process is being manifested in the two different cases.

And considering that, it is perhaps not surprising there is also another way of getting 'something out of nothing', which has been known since the 1990s, and it operates at an even more fundamental level. I am referring to the creation of a type of subatomic particle known as a baryon.<sup>13</sup>

Experiments have verified that the creation of baryon particles can occur when whirling vortices are created in a fluid medium such as Helium 3 (3He), a form of helium with the quality of 'superfluidity'. This phenomenon is an important part of some of the weird quantum effects associated with plasmas, as we shall see shortly, and it arises where liquids can flow without resistance. A key article revealing a particularly important finding about this was published in *Nature* in 1997, and I have kept that issue of the magazine folded over to that article to remind me ever since its publication in the spring of that year.

It was the group led by T.D.C. Bevan who published this key article about what they called 'baryogenesis' (baryon creation). <sup>14</sup> Bevan went on to publish much more about this type of thing over the succeeding years, but this particular article was the first time that the creation of baryons by this method had been demonstrated in a laboratory:

Here we describe experiments on 3He that demonstrate the creation of excitation momentum (which we call momentogenesis) by quantized vortices (flows around an axis at a quantum level of smallness) in the superfluid ... our results provide quantitative support for this type of baryogenesis [creation of baryons].

I cannot take space to explain this fully or do justice to the details, especially as it involves discussing quarks, chirality, 'spectral flow', and all kinds of things of that sort which are not necessary in this book, but may be found by consulting the many papers of Bevan and his teams directly.

The main thing to come out of all this is the demonstration that those nuclear particles known as baryons have been created in the laboratory, and

that they are also being created in a similar manner throughout space in superfluids, such as those to be found – as we shall discuss later – in dusty complex plasmas.

So we see clearly and repeatedly that it does not take something to create something, as it can just as readily be created by nothing.

So what is existence, if it can suddenly appear like that?

The plasma physicist who has done the most to call attention to the creation of matter within dusty complex plasma clouds is without question the Russian scientist Vadim Nikolaevich Tsytovich (born 17 March 1929 in St Petersburg, then called Leningrad, died 2015). For many years he published articles and books reporting on advanced findings from dusty complex plasma research showing that something which looks very like life can be produced in charged dust clouds.

In one article in 2007 he stated clearly:

It is concluded that complex self-organized plasma structures exhibit all the necessary properties to qualify them as candidates for inorganic living matter that may exist in space, provided certain conditions allow them to evolve naturally. <sup>15</sup>

Tsytovich and three colleagues including Sadruddin Benkadda were very specific about the self-organization within dusty plasmas of life-like phenomena, especially in an article that they published in 2000 and which I shall quote in a moment. But one technical word – dissipative – needs to be explained first. It does not refer to the common use of the word 'dissipation' to describe overindulgence in sensual pleasures. 'Dissipative' in this sense was first introduced into science in 1972 by the Belgian mathematical theorist Jan Camiel Willems (1939–2013), and became widespread because of its adoption and development by Ilya Romanovich Prigogine (1917–2003), the Nobel Laureate for Chemistry in 1977.

Prigogine entirely revolutionized the science of thermodynamics, which is essentially the study of the actions of heat and all that follows from them. Until Prigogine, it was widely believed that the Universe was steadily running down, that things slow down and fall apart, as the Second Law of Thermodynamics says they will.

What Prigogine discovered and proved was that energy brought into a chemical system, instead of always contributing by a process known as the increase of entropy ('the progressive increase of disorder'), could be

dissipated away into other directions and purposes that were productive and could form open, interactive structures such as life forms, known technically as 'dissipative structures'. These structures, being like isolated islands of positivity in a sea of increasing entropy and hopelessness, could instead become increasingly complex and self-organizing systems.

Prigogine built upon these discoveries his concepts of self-organization, which are now at the heart of what we are finding in dusty complex plasmas. So what Prigogine did was no less than explain the central role of life in the Universe. Although this was by no means heard by everyone, it was the philosophical death knell for the mechanical Universe.

And so we return to Tsytovich and his colleagues, and to plasma. Here are further comments made by Tsytovich and three colleagues in 2000:

Self-organization processes in dusty plasma are expected to be very important since the latter is an open system with a high rate of dissipation ... a high rate of dissipation provides rapid development of self-organization processes and formation of long-lived dissipative structures ... Dusty plasma is an open system where the rate of dissipation is high and there is a tendency to self-organization. New types of nonlinear interactions are possible in dusty plasmas. <sup>16</sup>

The importance of dusty plasmas being 'open systems' is that they can absorb energy from outside, which then fires the growth of complexity. The Kordylewski Clouds undoubtedly 'feed' on energy from the Sun in this way.

The next year, in 2001, Tsytovich published a paper 'Evolution of Voids in Dusty Plasmas' on the important subject of voids, or empty spaces, inside dusty complex plasmas. 'It is shown that formation of dust voids is a general phenomenon in dusty plasmas.' Voids are of immense importance in general, though rarely recognized. He went on to explain that whereas both dust structures and dust voids are formed in some plasmas, this cannot happen in a purely homogenous dusty plasma. There can be no internal architecture if the dust structures are not separated from one another by voids. A structure must be separated from the rest of the mass by a space, for otherwise it is no longer a distinct structure.

It is surprising how rarely people think of this. The human body is full of voids, and if it were not, you could not differentiate the kidney from the liver or the stomach from the lungs. Technically, these voids within our bodies are known as body cavities. And if the Kordylewski Clouds are to

have the complex internal structure that we know dusty complex plasmas to have, then they too must contain voids, or cavities.

In 2004, Tsytovich and his friend Gregor Eugen Morfill (another of the world's most distinguished plasma scientists) published a paper making clear that it is the non-linear character of the dusty complex plasmas which makes the self-organization of the internal structures possible:

Dusty plasmas are unusual states of matter where the interactions between the dust grains can be collective and are not a sum of all pair particle interactions. This state of matter is appropriate to form non-linear dissipative collective self-organized structures. <sup>18</sup>

They pointed out that such findings were compatible 'with recent results of structure observation in the experiments on the Inter-national Space Station.' There were numerous plasma experiments carried out on the Space Station, because scientists were eager to see how plasmas behave in a gravity-free environment. Many results have come from this work.

In 2014, a major paper was published by Tsytovich with Alexey Ivlev, Andreas Burkert, and his old friend and colleague Morfill. It was a long and important review article entitled 'Compact Dusty Clouds in a Cosmic Environment'. <sup>19</sup>

In this paper, Tsytovich and his colleagues pointed out that in order to be stable, a dust cloud must self-organize and fill itself with 'clumps' and internal structure. If a dust cloud remains smooth, it will be destroyed. They also said that such stable clouds can be as small as one-thousandth the size of the Earth and still cohere. So we have their assurance, therefore, that the Kordylewski Clouds must contain internal structure and be self-organized in order to have survived. And they further add that this is all possible while remaining 'optically thin', in other words, being invisible.

The authors also say that within dusty plasmas dust can confine itself into stable spherical clusters:

Spherical dusty clouds can be formed ... suggesting that this process of dust self-organization might be a generic phenomenon occurring in different astrophysical media. We argue that compact dusty clouds can represent condensation seeds [in other words they can provide the necessary conditions] for a population of small-scale, cold, gaseous clumps in the diffuse interstellar medium. They could play an important role in regulating its small-scale structure and its thermodynamic evolution ... Self-organization of dusty (complex) plasmas has been observed in numerous experiments. Different types of structures formed in dusty plasmas under microgravity conditions (in experiments performed on the International Space Station) as well

as on the ground include compact clusters, voids surrounded by dust shells, vortices, etc ... We predict that this process can occur in a broad range of plasma parameters, which indicates that such self-organization might be a generic phenomenon operating in different astrophysical media.

The giant spherical cosmic clouds discussed by Tsytovich and his colleagues, having between ten and a hundred times the distance of the Earth to the Sun as their diameters, are much bigger than our Kordylewski Clouds. And the giant ones he is discussing are also seen as forming in interstellar space between the stars, in a far thinner medium, whereas the smaller Kordylewski Clouds are in our own solar system, with a much denser medium, and with the constant feeding of energy into them by the solar wind.

Sergey Vladimirov, another of the most famous plasma scientists, has written:

The dust-plasma system is an open system. Strong interactions of dust particles and the openness of the system lead to self-organization and 'structurization' of initially homogeneous dust clouds into a complex aggregate of dissipative dust structures. These structures become quasi-stationary within short time scales [in other words, they very rapidly become almost stationary]  $\dots^{20}$ 

In another paper, Tsytovich, Morfill and four other colleagues stressed how plasma crystals inside the dusty complex plasmas could spontaneously form helical structures resembling DNA:

Complex plasmas may naturally self-organize themselves into stable interacting helical structures that exhibit features normally attributed to organic living matter. The self-organization is based on ... physical mechanisms of plasma interactions ... As a result, each helical string composed of solid microparticles [dust] is topologically and dynamically controlled by plasma fluxes leading to particle charging ... These interacting complex structures exhibit thermodynamic and evolutionary features thought to be peculiar only to living matter ... We examine the salient features of this new complex 'state of soft matter' in light of the autonomy, evolution, progenity and autopoiesis [autopoiesis refers to a system capable of reproducing and maintaining itself] principles used to define life. It is concluded that complex organized plasma structures exhibit all the necessary properties to qualify them as candidates for inorganic living matter that may exist in space provided certain conditions allow them to evolve naturally. <sup>21</sup>

This outspoken declaration could almost constitute a manifesto for the Kordylewski Clouds (though it was published twelve years before their existence was confirmed). Of course helical structures in humans have functions of storing and communicating information, so the crucial question

raised here is: could helical structures in plasma have the same function? And could these be the seeds of an alternative, evolving form of life? The authors go on to say:

Memory and reproduction are necessary for a self-organizing dissipative structure to form a 'living material'. The well-known problem in explaining the origin of life is that the complexity of living creatures is so high that the time necessary to form the simplest organic living structure is – 'seems' – too large compared to the age of the Earth ... Can faster evolution rates be achieved for non-organic structures, in particular, in space consisting mostly of plasmas and dust grains, i.e., of natural components spread almost everywhere in the Universe? If yes, then the question to address is: are the above necessary requirements of self-organization into a kind of 'living creature' present in plasmas containing macro-particles such as dust grains?

Here, we discuss new aspects of the physics of dust self-organization that can proceed very fast and present an explanation of the grain condensation into highly organized structures first observed as plasma crystal ... Our analysis shows that if helical dust structures are formed in space, they can have bifurcations [instances of splitting] as memory marks and duplicate each other, and they would reveal a faster evolution rate by competing for 'food' (surrounding plasma fluxes). These structures can have all necessary features to form 'inorganic life'.

This should be taken into account for formulation of a new SETI-like program based not only on astrophysical observations but also on planned new laboratory experiments, including those on the ISS [International Space Station]. In the case of the success of such a program, one should be faced with the possibility of resolving the low rate of evolution of organic life by investigating the possibility that inorganic life 'invents' the organic life.

The passage specifically says that helical dust structures can replicate, in other words, like helical DNA molecules, inside dust clouds. Inorganic living entities are then formed that 'compete for food' in the form of sources of incoming plasma, which they eat. (As we have seen, in the case of the Kordylewski Clouds, most of their 'food' consists of the solar wind coming from the Sun.) All of this happens at a far faster rate of evolution than is the case with organic life, and in its development would outpace organic evolution by billions of years, hence clearly gaining dominance.

From this point of view, we as organic humans are rather primitive latecomers to a fantastically ancient tradition of inorganic life forms. And as they say, 'a new SETI-like program' should be started. SETI, as many readers know, stands for Search for Extraterrestrial Intelligence. After all, who needs little green men when you've got gigantic intelligent clouds on your doorstep, which are billions of times more intelligent than any little green man could ever be, billions of years older than any possible organic life form, and the entities who must in effect be the true Masters of the Universe?

Throughout this book we will be looking at research from around the world, particularly America, which complements and reinforces the work of Vadim Nikolaevich Tsytovich and his colleagues.

With 'dust' made by the plasma itself replacing 'atoms' as the building blocks, living bodies can be formed. We might consider the charged dust to be 'dust atoms', or perhaps more accurately, 'dust molecules'. And from them, charged plasma entities can emerge by the process called self-organization. That means that no outside source needs to create them, as they can create themselves.

By this means, plasma people can exist, who are imperceptible to the optical nerves of the 'physical people' who are made not of plasma but of flesh and blood. Because we are incapable of directly perceiving the plasma people, we do not know they are there. And furthermore, they may be of such diffuse matter that they can pass through our dense physical matter and emerge intact. Scientists know that ball lightning does this, as we will discuss in Chapter 4. Spiritual beings such as angels are also said to have this capability, which we will come to in Chapter 6.

If what these scientists are showing – and I for one think they are – is that the internal structures of the two clouds could be so complex, and at such a vast scale, then they surpass any possible human knowledge at this time. The storage capacity for information would easily include the ability to retain full knowledge of everything that has ever happened in our local cosmic environment for four billion years. Everyone who has ever lived will be recorded. Every creature that has ever roamed the surface of the Earth will be recorded. Every plant which has ever grown will be as well. The presiding consciousnesses, or what psychologists call 'the executive ego states', of the two clouds will have personalities so alien from our own that we cannot conceive of them. Since the clouds evidently exist as a pair, they may be 'married'. (Or at least in a civil partnership?)

The questions are only just beginning.

### The 99 Per Cent

One accepts those incompatible things which, only because they coexist, are called the world

— Jorge Luis Borges

In this chapter, I want to discuss a very surprising assertion that is not at all well known to the general public and perhaps not well known even by scientists who work in other fields, but is universally accepted by scientists who do work in the field of plasma research. Alongside our atomic, visible world is the subtler universe of plasma. It is in our understanding of that 'other kind of matter' that ground-breaking progress has been made recently.

Some will no doubt say there is no 'other kind of matter', and that I must be talking nonsense. But the fact is that the existence of other kinds of matter, several of them, has been now proved. In fact so much has recently become known about them that we can now begin to have some proper understanding of them.

Let us start by talking about the most basic 'other kind of matter', which is called plasma today, and which was first properly 'discovered' as long ago as 1879, though not named until 1928 by Irving Langmuir, as we have seen.

We have already seen, too, that plasma is very different from 'physical matter'. 'Physical matter' is very rare in the Universe. At least 99 per cent, and some say more than 99.99 per cent, of the Universe is composed of plasma. We therefore live in a plasma universe, not a physical matter universe. But what does this mean?

What it means is that everything familiar to us on Earth is abnormal. What we call 'physical matter' exists in three familiar states: solid, liquid, and gaseous. These are, of course, exemplified in the three states of water: ice, liquid water, and steam. And until 1879, those were thought to be 'the three states of matter', beyond which there were no others.

Nowadays the fact that the Universe is made of at least 99 per cent plasma is accepted by all astronomers, astrophysicists, cosmologists and the other scientists concerned with those subjects, but the implications of this remain obscure.

And the fact that new kinds of plasma keep being discovered does not make it any easier. The latest forms of plasma are so extraordinary that they are frankly baffling. And the very small community of plasma scientists at work on these problems, some of whom I quoted in the previous chapter, are making an astonishing amount of progress, but are doing so largely without the knowledge of other physicists and astrophysicists.

Here is what some of the leading scientists in the field have to say:

Nearly all the matter in the universe exists in the plasma state, occurring predominantly in this form in the Sun and stars and in interstellar space.

(Anthony L. Peratt, *Physics of the Plasma Universe*, 2nd edition, 2015, p. 2.) Peratt was Scientific Advisor to the United States Department of Energy between 1995 and 1999. He was Acting Director of National Security, Nuclear Non-Proliferation Directorate, in 1998. Since 1981 he has been associated with the Los Alamos National Laboratory.

All but an infinitesimal part of the universe appears to be made up of plasma, probably all of it magneto-plasma. Thus in most problems in cosmic electrodynamics we are dealing with a non-rigid and electrically conducting medium extending to infinity ... the remainder of the universe is made up of various plasmas ... The plasmas with the lowest degrees of ionization are the lower parts of the ionospheres of the Earth and other planets. These regions are really boundary regions between the universal plasma and the small insulating, atmospheric shells.

(John Hobart Piddington, *Cosmic Electrodynamics*, 1969, pp. 24–5). 'Jack' Piddington (1910–1997) was Chief Research Scientist at the National Measurement Laboratory in Sydney, Australia, from 1966 to 1975.

It is likely that 99 per cent of the matter in our universe (in which the dust is one of the omnipresent ingredients) is in the form of a plasma. Thus, in most cases a plasma coexists with the dust particulates. These particulates [matter in the form of minute separate particles] may be

as large as a micron. They are not neutral, but are charged either negatively or positively depending on their surrounding plasma environments. An admixture of such charged dust or macro-particles, electrons, ions, and neutrals forms a 'dust plasma'.

(Padma Kant Shukla and Abdullah al Mamun, *Introduction to Dusty Plasma Physics*, 2002, p. 1.) Shukla (1950–2013) was Distinguished Professor and Director of the International Centre for Advanced Studies at Ruhr-University Bochum in Germany. Mamun is Professor of Physics at Jahangirnagar University, Dhaka, Bangladesh.

The three states of matter which occur at the surface of the earth are however not typical of matter in the universe. Most of the ... matter in the universe exists as plasma ...

(Marcel Goosens, An Introduction to Plasma Astrophysics and Magnetohydrodynamics, 2003, p. 1.) Goosens is Professor of Applied Mathematics at the Catholic University of Leuven in Belgium.

Scientific interest in high-energy plasmas has also been rekindled along with pragmatic interest, because the great bulk of matter in the universe is in precisely this exotic state. For about 95 per cent of the mass (neglecting dark matter), according to modern estimates, is the plasma of ordinary and neutron stars, pulsars, black holes, and giant planets of the solar system, as well as the recently discovered hundreds of planets beyond the solar system.

(Vladimir Yevgeyevich Fortov, *Extreme States of Matter on Earth and in the Cosmos*, 2011, p. ix.) Fortov is one of the leading scientists in the world in his field, and is currently President of the Russian Academy of Sciences.

... in most of the universe, plasma is actually the 'first' state of matter, and by a very large margin. Out there, fully intact atoms are abnormal in the extreme. Practically all the visible contents of the cosmos – not just stars, but even regions of rarefied interstellar dust containing barely a million particles per cubic metre – are in a plasma state.

(Curt Supplee, *The Plasma Universe*, 2009, p. 1.) Supplee is a science writer who has won the Science Journalism Award from the American Association for the Advancement of Science, and other such awards, and has been nominated twice for the Pulitzer Prize. At one time he was Director of the Office of Legislative and Public Affairs at the National Science Foundation in the USA

Plasma physicists know that ... the universe is not made up of 'invisible matter' but rather of matter in the plasma state ... electric plasma ... fills more than 99 per cent of the universe.

(Donald Edward Scott, *The Electric Sky*, 2012, p. 3.) 'Don' Scott is retired Professor of Electrical Engineering at the University of Massachusetts/Amherst.

Among all objects observed in nature, about 90 per cent exist in ionized form. Plasmas, often considered the fourth state of matter, span a huge diversity of parameter scales and exist throughout the universe.

(Michael Bonitz, et al., *Introduction to Complex Plasmas*, 2010.) Bonitz is Professor and Chair of Statistical Physics at the Institute of Theoretical Physics and Astrophysics at Christian-Albrechts-University at Kiel in Germany.

Under ordinary terrestrial conditions the plasma state of matter is quite rare and unusual. But in the universe, cold solid bodies such as our Earth appear to be a rare exception. Most of the matter in the universe is ionized, i.e., it exists in the plasma state ... In our own solar system the Sun consists entirely of plasma, its mass being three hundred and thirty thousand times larger than the mass of the Earth. The upper layers of the Earth's atmosphere are ionized by the Sun, i.e., they consist of plasma ... Many plasma phenomena are evident on a colossal scale in deep space ... In our opinion mankind is entering into the space age which, to a considerable degree, is also a plasma age. This new stage in the growth of science and technology imposes increasing requirements on the youngest branch of physics, plasma physics.

(David Albertovich Frank-Kamenetskii, *Plasma: The Fourth State of Matter*, 1972, pp. 2–8.)

... space is not empty. A percentage of atoms in space are positively charged due to the loss of one or more electrons. The resulting exceedingly thin medium, containing positive 'ions' and negative electrons, is plasma, sometimes called 'the fundamental state of matter' since it constitutes more than 99 per cent of the visible universe. The electromagnetic behaviour of plasma clearly distinguishes it from solids, liquids, and gases.

(Wallace Thornhill and David Talbott, *The Electric Universe*, 2008, p. 6.) Thornhill studied physics and electronics at the University of Melbourne and subsequently became an independent scholar. Talbott is an independent scholar.

The properties of plasmas are of paramount interest in cosmical physics because most of the matter in the universe is in the plasma state. In the interiors of stars the gas is almost completely ionized ... Vast regions of interstellar space around the stars ... are highly ionized ...

(Hannes Alfvén and Carl-Gunne Fälthammar, *Cosmical Electro-Dynamics: Fundamental Principles*, 1963, p. 14.) Hannes Alfvén won the Nobel Prize for Physics in 1970. Fälthammar is Professor Emeritus at the Royal Institute

of Technology in Stockholm, where he succeeded Alfvén as Professor of Plasma Physics.

Most of the universe is plasma ... As astronomers began to realize that the universe is mostly plasma, they also came to the conclusion that plasma physics might help to explain many of the unanswered questions about how stars are created, and how they die out. Plasma physicists began making important contributions to astronomy and cosmology in the 1950s. Then, in the 1960s, startling discoveries burst upon the astronomers. Quasars and pulsars, exploding galaxies and disappearing stars all clamoured for explanation. In all of these exciting and strange new phenomena, plasma physics plays a key role. For there are cataclysms exploding in the heavens of a violence undreamed of even a few short years ago. And only plasmas are energetic enough to undergo such shattering catastrophes. To understand what's happening in the heavens – to understand how our own Sun and Earth were born and how they will die – we must understand plasma physics ... The 'emptiness' between Sun and Earth, then, is actually a rich domain of plasmas and electromagnetic energies.

(Ben Bova, *The Fourth State of Matter: Plasma Dynamics and Tomorrow's Technology*, 1971, pp. 28–31, 90.) Bova is a popular science writer, former editor, and former President of the National Space Society in the USA.

It is often said that 99 per cent of the universe is in the plasma state ... The Earth's atmosphere, too, becomes a plasma beginning about 100 km above the Earth's surface.

(Atsuhiro Nishida, *Atmospheric Plasma Physics*, Vol. 4, 1982, p. vii.) Nishida is Professor Emeritus of the Institute of Space and Astronautical Science in Japan.

From the range of authoritative comment shown here, we can see now that there is an overwhelming consensus among scientists researching in this area that the Universe is mostly a plasma universe, and that what we call 'physical matter', or what I prefer to call 'atomic matter', since it is not plasma, must be very rare indeed. And plasma is the fundamental building block of atomic matter:

 $\dots$  a plasma is the first state of matter out of which all the other states of matter originated  $\dots$  Nature began with the plasma.

(Vinod Krishnan, *Introduction to Dusty Plasma Physics*, 2014, pp. 1, 2.) Krishnan is Senior Professor and Dean of Sciences at the Indian Institute of Astrophysics, Bangalore, India.

Nature began with the plasma. Cooling of the plasma converted it into a gas. Cooling of the gas converted it into a liquid. Cooling of the liquid converted it into a solid ... That plasmas are the first state of matter out of which arose the other three states of matter has been amply

demonstrated. The ubiquity of plasmas in the universe needs no demonstration. The phenomenal diversity of plasmas is there all over the universe for all to see.

(Vinod Krishnan, *Plasmas: The First State of Matter*, 2014, pp. 1, 40.) See above.

#### Turning everything upside down

Anyone who thinks he or she has never seen plasma hasn't been outside lately. As we have mentioned, the Sun and stars are made entirely of plasma. It seems likely that the giant planets Jupiter, Saturn, Uranus and Neptune are also made largely of plasma. There is a sphere of plasma surrounding the Earth, called the ionosphere. Above that is the magnetosphere, which was given its name in 1958 by Professor Tommy Gold.

The magnetosphere contains huge regions of plasma within the Van Allen Radiation Belts, which were named after their discoverer, James Van Allen, who found them in 1958. (Later we will learn the details of how that occurred.) We see plasma in thunderstorms, because lightning is plasma. Fluorescent lighting occurs when you turn on the switch and electricity shoots through a tube containing a gas such as neon; during the time it is turned on, that tube contains plasma. When you turn it off, the contents of the tube revert to ordinary neon again, which no longer emits light, and all the plasma is gone. Your flat TV screen contains plasma when it is turned on. So you see, plasma is everywhere and we see it every day that the Sun shines or when we are watching television. It is simply a matter of knowing what you are seeing (or not seeing).

In light of what we now know about the predominance of plasma in the Universe, we really need to turn our physics on its head. Instead of trying to model the Universe on the basis of the very rare and specialized form of dense matter found on our planet, we need to treat dense 'physical matter' as an exceptional form of the true 'universal matter', plasma. There is no use in our trying to establish universal laws on the basis of a tiny sample of far less than one percent of what exists. We need to establish physical laws on the basis of plasma and specify what we call 'physical matter' as a very

special and limited case, which has no justification for being used as a basis for describing the majority constituents of the Universe.

So drastic does our rearrangement of science need to be that we can take our present physics, shrink it and plonk it into a tiny corner of the representation of the wider truth, where it can describe those minority conditions appertaining to planets and other such 'solid' bodies, as a kind of footnote or addendum to a true universal science. None of our human scientific work so far need be wasted, for it can all provide a very useful account of what goes on in those rare, small 'solid' bodies where dense matter predominates and where such atypical conditions apply.

Scientists residing in the plasma realm could read and study this with the greatest of interest, in the way that we study the strange conditions found in deep-sea thermal vents, astonished that such life forms can exist. Indeed, we as humans might even attract some useful attention to ourselves and find ourselves becoming a niche attraction, like bearded ladies in a circus.

We cannot therefore draw conclusions about universal truths based upon a highly divergent, atypical, and almost infinitesimally small percentage of what exists. We cannot be certain that any of our physics is universally applicable and hence 'true' in the sense that we have complacently assumed.

Before I begin the history of human encounters with and understanding of plasma, I want to return to the subject of a seemingly naturally occurring manifestation of plasma which, although relatively rare, is dramatic and may help us understand the descriptions of various religious phenomena in ancient history, as well as helping us to understand a way that plasmas such as the Kordylewski Clouds might interact with us.

## Great Balls of Fire

Ball lightning has been puzzling people for thousands of years. It is surprising that, despite the fact that numerous photos and film of ball lightning exist, and the fact that it can even be artificially created in the laboratory (this was first achieved in St Petersburg in 1753 by Georg Richmann, though it killed him), there are still people who grumble and complain that it doesn't exist.

Ball lightning is a 'plasmoid', which is to say a blob of plasma. There are several fascinating books about ball lightning. One of them, *Ball Lightning* by Mark Stenhoff, published in 1999, has however the ominous subtitle *An Unsolved Problem in Atmospheric Physics*. Ball lightning is indeed still an enigma, and it may have some connection with the Kordylewski Clouds, as I shall also explain later.

Very briefly, ball lightning is generally a spherical or nearly spherical glowing ball of fiery light that rolls along the ground or flies through the air, and sometimes passes through solid walls and emerges intact on the other side. It has sometimes been seen rolling down the aisles of passenger planes and frightening people.

The first book on ball lightning ever published in Britain, and the first I ever saw, was *The Taming of the Thunderbolts: The Science and Superstition of Ball Lightning*, by C. Maxwell Cade and Delphine Davis.<sup>2</sup> It was published in 1969, and I came across it and bought a copy in the very early 1970s. They used the word 'thunderbolts' to describe ball lightning, because that is what it was called in ancient times, and the early part of the book traces the history of accounts of what was probably ball lightning in the Bible (Ezekiel) and the classical authors Pliny and Lucretius up until modern times. They collected 107 case history accounts and in their

Acknowledgements they said that they spent five and a half years researching the book and wrote 'almost 1000 letters with correspondents in sixteen different countries'.

At the time the book came out and in the years immediately following, there were derisory reactions, and the authors were assailed by many scientists as having written about something that did not exist and was a mere fantasy. There are now hundreds of scientific publications about it, it has often been photographed, and there are many films of it easily available on YouTube. There is no doubt that it not only exists but has existed throughout the whole of recorded human history, and doubtless for the whole period of existence of our planet.

Ball lightning is indisputably electrical in nature (whatever theory one has for how and why) and has several characteristics in common with traditional descriptions of ghosts. For instance, if there is a high wind and a sphere of ball lightning appears in the air, it can move steadily against the wind as if the wind were not blowing. In other words, the wind does not appear to effect it in any way, even though the glowing sphere is generally rather small, so that it should be so light in weight that the wind would blow it away very fast. Spheres of ball lightning can also, as I say, sometimes pass through solid walls and emerge intact on the other side as if the walls had not been there. This is what ghosts are often claimed to do.

I am not necessarily suggesting that most ball lightning of the usual sort is intelligent, but it is also possible that some ball lightning phenomena are associated with intelligent entities, and are even 'plasmic drones'. I say this because a minority of reports describe their behaviour in such a way that suggests intelligent control of their movements, as they seem to be inspecting people and things, and also spotting, pursuing, and entering aircraft in flight, which presumably would be impossible for a mindless entity, or one that was not remotely controlled by an intelligent entity as a probe.<sup>3</sup>

Considering the existence of the Kordylewski Clouds, and my suggestion that they are intelligent, it makes sense that they would want to monitor what is going on here on Earth. And so what would make more sense than to have plasmoid reconnaissance? I therefore suggest that many of the balls of lightning and similar phenomena, and hence also many UFOs, are scouts

and surveillance drones operated by the clouds. The sudden movements observed in so many glowing UFOs, the right-angled turns, the rapid disappearances, the vast speeds, the ability to go underwater and re-emerge, and so on, all make instant sense if one assumes that they are probes from the plasma clouds.

The storage capacity for information of the two clouds, which together are nine times the size of the Earth, means that the entire history of humanity could be stored in them, as suggested earlier, and that the US National Security Agency's super-computers in Utah, which store all the telephone and internet communications on Earth, are ridiculously puny by comparison. It is impossible to resist the suspicion that the clouds know so much more about Earth events than all the security agencies in the world combined that any attempt to equal their surveillance powers would be futile. Plasmoid reconnaissance and surveillance drones would not need to be operated by anyone, but the clouds may have created robotic physical entities to act for them.<sup>4</sup>

In considering ball lightning further, there are certain fundamental texts that must be consulted. There is, for instance, a group of three inter-related books by three different authors who all assisted one another. Two of them were Americans with access to extensive files of defence contractors, NASA, and the US Air Force and US Navy, and the third was a British friend of theirs. The three books are:

The Nature of Ball Lightning by Stanley Singer (1971)

Ball Lightning and Bead Lighting: Extreme Forms of Atmospheric

Electricity by James Dale Barry (1980)

Ball Lightning: An Unsolved Problem in Atmospheric Physics by Mark

Stenhoff (1999).<sup>5</sup>

The authors of all three of these books shared the same basic bibliography, which is a truly enormous one. Singer's book (which lists 594 references in many languages) was largely funded by defence sources. As he says in his Preface: 'A major portion of the work was supported by the Office of Naval Research.' It was clearly through these defence contacts that many reports, translations of foreign works, and publications that have never been made

available to the public were included in the bibliographies and apparently shown to the authors for personal consultation.

These include, for instance, private reports or translations on ball lightning commissioned by the private defence contractors Raytheon Corporation and Avco Corporation. (The latter company in 1960 built an experimental aircraft for the US Air Force that was shaped like a flying saucer or 'flying disc'. As for Raytheon, 'everyone knows about them', by which I mean that one is continually reading and hearing that they are part of the 'military and security establishment'.) By looking through the bibliographies of these three books, we can see how seriously the American and Soviet governments were taking research into anything to do with plasma.

Numerous researchers thought ball lightning might be harnessed for weapons, such as the directing of balls of lightning at enemy tanks and planes. So, of course, when there is any possibility of devising new and improved ways of killing people, the money always pours in to support research. A very large proportion of the research that was carried out in America and the Soviet Union on ball lightning remains secret and will probably never be released.

Singer and Barry, mentioned above, collaborated on a joint paper delivered to the First International Symposium on Ball Lightning, which was held at Waseda University, Tokyo, on 4–6 July 1988. Singer was also an advisor to the Organizing Committee of the conference. The conference was attended by fifty-four scientists from eight different countries, under the Chairmanship of Professor Yoshi-Hiko Ohtsuki. The conference was held outside of government sponsorship or control, and was sponsored by a group of nineteen major Japanese corporations, including Fuji, Honda, and Sony. The Proceedings of the conference were published in 1988 and contain a great deal of important information, and although I have a copy myself, these Proceedings are now unobtainable for sale. Anyone interested in ball lightning should try to find library copies of these important Proceedings.

Skimming quickly over some of the strange ball lightning phenomena that have been discussed at such length in numerous books and articles, with hundreds of case reports, we find that ball lightning can enter closed rooms and buildings; it appeared frequently inside Second World War American submarines running along the floor; and it has often occurred in airborne planes. It also goes up and down chimneys, and it sometimes appears to 'inspect' things such as patterns on carpets; it can explode, it can be dangerous, and it can even kill people on rare occasions. Usually it is harmless, but sometimes it is deadly.

Another more recent book on ball lightning is *Ball Lightning: Paradox of Physics* by Paul Sagan (2004).<sup>7</sup> This interesting book concentrates on classifying the bizarre phenomena associated with ball lightning, which the author often calls 'fireballs'. The author has headings such as 'fireballs endanger Hill Air Force Base', 'fireballs defy gravity', 'line rollers', 'flyers and bouncers', 'airplane crashes', 'dazzlers and hissers', 'mechanical damage', 'electrical and heat damage', 'electrical effects', 'trees emit fireballs', 'atop cooling towers', 'fireballs eat lightning', 'colliding fireballs', and 'shrinkers and expanders'.

These things are not made up, they are real phenomena. All of these bizarre events represent intrusions of plasma into our world of dense physical matter. Sagan has an important section called: 'Do Flying Fireballs "Think"?' This is not as fantastic as it sounds. Here is some of what he says:

But fireballs possess sensory, energy generation, navigation and propulsion systems. Since ball lightning is buoyant, how come some fall rapidly from clouds like falling cannonballs, rebound before hitting the ground, and then float lazily against the wind or rapidly shoot back up to the clouds? How does a ball 'know' where an aircraft is, follow it closely and not be affected by the 500 miles-per-hour airflow and turbulence, and not just tumble or be swept away in the wind and turbulence? What possible detection, sensory, energy generation, navigation and propulsion system do fireballs possess? No other natural or man-made control feedback system matches their incredible behaviour.

A microprocessor-based system or fireball with sensors that can materialize and fly, then detect electromagnetic, electrostatic, metal, solid objects, chimneys from a distance, distinguish a standing person from a post, and so on, would be an amazing feat of technology. But, for a supposedly hot ball of gas – it is not made of semiconductors and wires – to do these tasks of sensing, control and navigation is not a question for technology, but a mystery of physics. <sup>8</sup>

Paul Sagan has made one major error in this passage from his book. He implies that these 'balls of gas' are not made of semiconductors and wires. On the contrary! As we will see in Chapter 11, plasmoids can indeed have the equivalent of semiconductors within them, and as for 'wires', Sagan is

referring to copper wires no doubt, but much more efficient means of carrying directed current exist than 'wires'! We have to stop thinking in terms of physically dense matter. As we will see shortly, semiconduction does not require physically dense substances like silicon and germanium microchips, and the transmission of current does not require wires of any kind!

Plasma equivalents of both semiconduction and wires are fundamental to complex plasmas, especially to plasma crystals. And it appears that some fireballs, or lightning balls, are indeed complex plasmas, and as we will see later, the ones that are of that kind can be full of internal 'cells', semiconductor regions, and filamentary current carriers galore. We have begun building the argument to show that internal structure self-organizes and 'emerges' from dusty complex plasmas, and some of the lightning balls are probably of that category of plasma.

There are so many fantastic aspects to ball lightning, recounted at great length in the various books and hundreds of articles, that it would be pointless for me even to begin to try to summarize them all here. Ball lightning has clearly often been responsible for some UFO sightings, and that is something that requires no imagination to understand. More troubling are the connections of ball lightning with poltergeist phenomena and spontaneous combustion of human beings. There are accounts of people having been burnt alive, but their clothes left unharmed by the 'fire', and sometimes even their skin has been left unharmed.

And as for poltergeist connections, lightning balls have been associated with strange incidents where the contents of closed rooms have been smashed as if by angry ghosts. Psychical researchers have often been called in to cases of apparently paranormal phenomena, which are associated with lightning balls, just as UFO researchers have often had reports of UFOs that turned out to be ball lightning.

Two other major efforts to deal with ball lightning in book form need also to be mentioned. The first is an entire volume on the subject issued by the Royal Society in London in 2002. This was edited by John Abrahamson. It formed an entire theme issue of the Philosophical Transactions. This was a remarkable breakthrough for ball lightning research, because it showed that the highest levels of Scientific

Establishment respectability were being accorded to the subject within the civilian context (as opposed to the secret military and security contexts). In short, ball lightning research had now 'come out of the closet'. No longer were stuffy scientists going to say that only cranks and lunatics could discuss this subject, and treat those scientists who dared to do so as renegades.

The Royal Society volume included a contribution by Stanley Singer, whose important book on the subject of 1971 (supported by the US Navy) I have already mentioned. At last he could come fully out of the shadows on this subject! The volume also included contributions by the Russian scientists Alexander Vladimirovich Bychkov and Vladimir Lvovich Bychkov, who have major international reputations. (Vladimir Bychkov is a co-editor of the book *The Atmosphere and Ionosphere: Elementary Processes, Discharges, and Plasmoids*, published in 2003 by Springer Verlag, which also contains some material about ball lightning.) The other publication deserving of attention, by the Torchigins, for reasons of space is described in a footnote. <sup>10</sup>

Going back a bit in time, in 1943, the Mexican scientist Manuel V. Cerrillo was the first person to suggest (in a report written in Spanish for the Mexican Government) that ball lightning is a 'standing wave' or 'soliton' phenomenon. We will come to an examination of these in Chapter 11. What is important here is that lightning balls are, as I have already suggested, an example of extremely fine structures that are able to move through space and also through denser objects while keeping their shape and internal structure. In this way one of the weird phenomena at the subatomic level described by quantum mechanics – called solitons – can also happen at the macro level in plasma.

On the other hand, ball lightning sometimes seems to shatter when it strikes a surface. It can hit you with a whammy and electrocute you, or it might strike you and be harmless. The subject is still mysterious and there is a lot to learn. One thing does seem sure, namely that plasma is involved.

I have seen ball lightning only once. My wife and I were driving one night during the 1970s on the road north from Banbury in England. Olivia was at the wheel and I was in the passenger seat, and I saw a strange light sitting in a tree about fifty feet away to the left of the road. It was an eerie

glowing sphere of mixed red, white, pink, and orange light. My estimate of the size of the sphere is that it must have been about four feet across (about 1.3 metres). It did not move, it sat motionless on a tree branch.

Because my wife was driving very slowly on a dark two-lane road in our old Morris Minor, I was able to observe the ball for a minute or two clearly. It seemed to consist of a luminous gas, which was effervescent and fiery. If it gave out a sound or smell I could not have detected either, because of the noise of the car engine and my distance from the ball. (Ball lightning often hisses and gives off smells of sulphur or brimstone.) There was no thunderstorm activity going on at the time, and it was a quiet evening. So that is the sum of my limited personal experience!

My sighting was unusual in only two senses, first that the ball was motionless, and second, that it persisted for longer than usual, as ball lightning often vanishes very rapidly. I also had the uncanny feeling that the ball was 'alive', which I then decided could not have been true, but nevertheless, that was the subjective impression it gave, as I had a distinct feeling of being watched by it. That is the feeling one often has when being stared at from behind, and you turn around and there really is someone staring at you. And it was like the way that a barn owl perching on a gatepost seems to stare at you penetratingly in the flash of the headlights as you drive past it on a country road late at night. I wanted to go back and investigate, but there was nowhere to pull over, it was late, dark and cold, and so we did not bother.

I have on one other occasion had the impression that I was being 'observed' by a plasma, so I shall briefly mention the incident. During 2014 or 2015, my wife and I were asleep in a hotel room in Paris, where the usual flat screen plasma TV set was mounted on the wall. I woke up from a deep sleep suddenly, because I felt that someone was staring at me. I opened my eyes very quickly without moving, and I could see that the TV set had somehow turned itself on and had a grey screen showing visual static, with no sound at all. There was no broadcast being received, and the remote control was far from the bed and we had never touched it during our stay. I had the subjective impression that the TV set was alarmed to see that I had observed it watching me, and being on when it should not be, so it immediately turned itself off and faded to black.

That is the only time that has ever happened to me, but on a few occasions TV sets and DVD players have turned themselves on suddenly when I have been in the room, and in one case a machine spontaneously went through a sequence of three separate 'on' switches to start working of its own accord. However, on none of those occasions did I have the creepy feeling that someone was watching me.

One night in my office when I was working late writing something, the office printer turned itself on of its own accord and spewed out an A4 page with a photograph of my very close friend Michael Baigent, who had died not long previously. I had not touched anything but my keyboard as I worked on a document, and the printer had been turned 'off', remaining only on standby (i.e., the electric power was still on but the machine was off). The photo had been stored in my computer amongst hundreds of other photos and I had not looked at it for months. I took this as a 'Hello!' from my friend Michael.

When I told his wife Jane about it the next day and emailed her the photo that had self-printed, she was shaken, but very cheered up to think that he might have sent a message letting us know he was still alive, though 'dead'. But just so that we could not possibly misunderstand from whom the message came, there was Michael staring up at me from the paper with that mischievous look which he often had whenever he was telling me something especially provocative or unusual.

My own theory is that ball lightnings are charged plasma crystals containing a massive amount of microscopic dust particles, which become visible under certain conditions.

As early as 1955, the famous Russian physicist Peter [Pyotr Leonidovich] Kapitsa suggested that ball lightning was a spherical plasma. <sup>11</sup> He began his article of that year by saying: 'The nature of ball lightning is not yet understood.' That's for sure! His main question here is 'where does the energy for the ball come from?' He does many calculations and makes assumptions, some of which since 1955 have become obsolete, and are entirely based upon classical physics. I shall skip his discussions of energy sources, sizes, durations, wavelengths, etc., much of which I believe to be today irrelevant, and look instead at the part of his article that is still of continuing interest.

Kapitsa believed that lightning balls were formed in the following manner: 'Initially, there exists a volume of plasma, which is small ... (and) weakly ionized ...' But then it resonates with and becomes excited by radiation, which 'causes effective absorption of radio waves. Because of this, the ionization grows and with it also the initial volume of the sphere, which as yet has not reached a diameter (d). Eventually, the resonance characteristics of the absorption process will be determined only by the geometry ...'

This may sound a bit confusing, but what I want to stress is his bringing in the essential matter of geometry. To my knowledge, nobody had ever done this before. He is referring to the geometry of radiation coming from 'a source of energy still unknown to us', which is 'outside of the volume of the lightning ball' and has created an electric field. In other words, he conceives of the electric field that supplies the energy for the lightning ball as having geometry. <sup>12</sup> (See the footnote for some further details of very great interest.)

It is not necessary for the reader to know any more of the complicated technical details than this. Kapitsa is invoking what we can now see is a crystalline structure of an electric field. Electric fields always have structure of some kind, which can be suggested by drawings of shapes of the fields using the device known as 'lines of force' as visual aids. But a crystalline structure is a different matter. It is a rigidly fixed pattern, which is a more ordered kind of structure, a higher level of order for a field. Such phenomena had never been imagined before.

Of course, Kapitsa did not think of it like that or 'see' that. He was (as my footnote makes clear) thinking of nodes, antinodes, and resonance points in the sense of their being action points or foci. He did not conceive of them as being joined in a structural entity. I look at this differently, and I see those points as vertices of a geometrical plasma crystal. But having adopted my conception of the plasma crystal, we can use Kapitsa's scheme and other similar ones as the internal structural maps of those crystals. And such resonance phenomena as Kapitsa invokes from his 'unknown energy source' could even be formative causes of the plasma crystals.

Readers may wonder about what it means to call a plasma crystal a crystal. After all, we are used to holding gems and quartz and such things in

our hands, turning them around, looking at them gleam, or wearing them in rings and bracelets, etc. What possible justification can there be for calling a cloud of plasma in space or a ball of plasma 'crystalline'? Well, it is really a scientific convention, perhaps illuminated by words on 'what is a crystal' from an essay by Eugene Wigner, who won the Nobel Prize for Physics in 1963:

X-ray studies have revealed that most of the solid bodies in our surroundings are crystalline. This does not necessarily mean that they are formed by one single crystal – although even this can be true for bodies of such enormous size as icebergs. More commonly, they are polycrystalline, like the metal parts of ordinary tools, i.e., a conglomerate of microscopic crystals of various sizes. Crystalline in this connection does not mean a regularly shaped body of the kind we see in our crystallographic collections [such as museum crystal mineral specimens], but only that the grains have a regular inner structure arising from the arrangement of the atoms in surprisingly regular lattices ...

The crystalline and polycrystalline substances constitute by far the greater part of all solid bodies found in nature. Practically all rocks are conglomerates of crystals, ice is crystalline, and so are all metals. The grains of sand are minute crystals and loam also is crystalline. Apart from the glasses and substances of organic origin, like wood, there are very few non-crystalline solids

The enormous differences between the physical properties of different kinds of lattices make it evident that the forces holding the atoms or molecules together are very different ... in the ionic lattices [the constituents] are charged particles. The electric forces between ions are very strong ... These lattices are always so constructed that the positive ions are surrounded by negative ions, the negative ions by positive ones ... Since opposite charges attract each other, there are considerable forces holding these lattices together. <sup>13</sup>

Wigner thus explains crystals in the wider sense to his readers: the constituents of a crystal (which for a plasma crystal means positively and negatively charged ions and particles) form a lattice. This means that the crystal has an ordered inner structure. As we will see later, this inner structure can be very useful in the storage of memory, computation and other faculties of intelligence.

And in space, plasma clouds that are crystalline are undoubtedly polycrystalline and consist of myriads of smaller crystals. If you or I were able to stand in space next to a plasma crystal we could only 'see' it if we had magic powers. Its constituent particles are far too small for the human eye to see, even with our microscopes. So there might appear to be nothing there. And such plasma crystals, especially if they are polycrystalline, can extend for gigantic distances. As Wigner pointed out, an iceberg can be a single crystal. And they can be huge. So we must never assume that a

plasma crystal, or a plasma polycrystalline cloud, need have any size restrictions such as a non-scientist might otherwise imagine. And frankly, there is no reason why such clouds cannot be the size of a whole galaxy.

From such a perspective, our local Kordylewski Clouds are tiny and verging on being insignificant. They only seem large to us. I will add one more thought: try and imagine the intelligence of a plasma cloud the size of a galaxy. People are always talking about 'intelligent life in space' and wondering where 'they' are. But 'they' may be hiding in plain sight. Considering that our sun is made of plasma and that stars are therefore also made of plasma, it is entirely possible that everything you can see in the night sky that is not one of our own satellites is alive and intelligent. Big red, white, yellow, and blue stars may really be the 'little green men'. Time to rethink.

In 1975, the British mathematician and scientist Harry Jones published a brilliant book about electrons.<sup>14</sup> The gist of it is that free energy in the form of electrons that are bouncing around in a crystal will form complete spheres.

This helped me to understand in more depth what Kapitsa said in 1955 and to develop my own ideas. When I read this, it became immediately apparent to me that if we visualize ball lightning as charged dusty plasma crystals, the fact that the surfaces of crystals containing constant energy form complete spheres when freely suspended in a medium, explains the spherical shapes of lightning balls, which has been puzzling scientists forever.

Convincing graphic evidence of the crystalline structure of ball lightning may be seen in an astounding photo taken in 1955 by a Swiss amateur photographer named F. Goepfert, which was published for the first time in 1965. I reproduce a section of this black and white photo in Figure 4. The full photo shows three successive images of ball lightning flashes side by side, which because they took place within 40 to 100 microseconds of each other all appeared on the same photo (which had an exposure time longer than that).

The portion reproduced here (reduced from three to two images because of space) shows two of them side by side. They are essentially identical. (The third, not shown here, was the same.) What this demonstrates is that

the visible electric charges were following the same complex paths repeatedly within the same crystalline structure. Otherwise, the flashes would have been random and would have varied, but they could not have replicated themselves.

We need to think in terms of three dimensions when looking at this two-dimensional image, noting that some of the lines cross one another when seen on the flat, but that is an illusion because of flattening the three-dimensional image. The electricity was in fact flowing along surfaces, points, and interstices and turning at vertices within the crystal. A clever geometer could probably even reconstruct the crystal from the path of the electric current. This kind of behaviour is typical of the phenomena studied in a new discipline known as 'topological physics', where currents run along edges and hinges of solid geometrical forms. Plasma crystals have geometrical configurations, with surfaces (called 'boundaries' when speaking of plasma), edges (or 'hinges'), and vertices (or 'nodes').

Figure 4. A portion of Goepfert's photo taken in 1955 showing two of the three identical current paths of arc-mode current flashes travelling through the same lightning ball and occurring microseconds apart so that they all appeared on the same photograph side by side. This evidence substantiates the theory of ball lightning being charged dusty plasma crystals. If plotted in three dimensions, the current path would help us to reconstruct the invisible host crystalline structure. If the current paths had been randomly created, they could not have been the same like this. Just to be clear, this is a photo not of a lightning ball itself but of current flashes travelling through part of a

lightning ball, showing only a portion of that ball, which is why the image itself does not look like a ball!

We have just seen Eugene Wigner's helpful explanation of crystals that are not the solid objects with which we are all familiar. Plasma crystals are not solid and they are made of charged particles and ions, containing a crucial admixture of microscopic dust particles that make the crystalline structure possible. Most of them are invisible to our eyes and weigh essentially nothing.

As I explained early in this book, when I stressed that the Universe is made of 99.9 per cent plasma, so that solid dense matter is very rare and atypical, so I must now stress that it follows that plasma crystals are very common and pieces of quartz and gems are very rare. We must not take what is familiar to us in daily life as the basis for trying to understand the Universe, as that gives us a wholly distorted picture of reality. Let's put it like this: no one living in the plasma universe would have any interest in our quartzes and gems made of atoms of dense solid matter. They are only important to us. We need to stop being flat-Earthers and 'get real'.

This means that there may be 99.9 per cent more plasma crystals in the Universe than there are dense matter crystals like quartz. So if we can get our heads around that, we can begin to see the light. We simply have to keep struggling to pull ourselves out of an Earth-centric view of things and get a plasma-centric one instead, if we want to understand the Universe properly.

This has all kinds of implications. Plasma crystals are capable of being fantastically complex, and complex in an ordered and dynamic way needed for intelligence.

In this chapter we have seen that ball lightning, made of plasma, has the ability to move through solid objects with its form unchanged. In this it exhibits the same weird behaviour that is observed in the quantum realm in the form of what are called solitons. We have seen that complex dusty plasmas contain crystals that give them form, and we shall see later are crucial to understanding why plasmas may develop intelligence.

In the next chapter we will look at human experience of the intelligent behaviour of plasma phenomena in ancient times, some of which seem much like experience of lightning balls. In Chapters 7–10 we will look at the observations, research, calculations and theories of astronomers and astrophysicists regarding plasma in space in modern times.

In Chapters 11–13 we will see how work on plasma in laboratories has confirmed and intertwined with the work of the astronomers and astrophysicists.

In Chapter 14 we bring all this together to summarize the arguments that complex plasma can be intelligent. We will see that intelligence of complex plasmas such as the Kordylewski Clouds may not be exactly like ours, and speculate that it may be more like the artificial intelligence and quantum computers now in development.

Then in the last section of the book, Chapters 15–17, we will look at the plasma inside our bodies and ask what the implications are. Is our own intelligence in some way dependent on this plasma?

## When Heaven Was Young

For the whole of recorded human history, many traditions and tales have survived where humans in a state of meditation or reverie have encountered glowing balls of fire of a divine nature. Let us take a look now at some of these ancient accounts. They provide historic evidence of great importance to us.

About two thousand years ago, there was a very widespread religious tradition in the Middle East and Mediterranean based upon what we would now call plasma entities. It was a 'light-theology' called Gnosticism. There were many 'schools' and groups and churches of Gnosticism, somewhat similar to the way in which there are many Protestant sects today. The word 'gnostic' is a modern invention, which scholars use to describe them collectively. It comes from the Greek word *gnōsis*, which means 'knowledge', but amongst the people we now call the Gnostics, the word took on a deeper meaning of 'sacred knowledge', or of 'higher knowledge'.

The Gnostics believed that an elect group of people of spiritual inclinations who pursued sacred knowledge would constitute the section of the human population, who would survive the vicissitudes of the corrupt world of physical matter, and after their physical deaths would enter a Kingdom of Light, in which resided a variety of plasmic deities culminating in 'the Father'. This was a name they used for the highest god of all. Jesus used this very term himself and instead of speaking of the Kingdom of Light, he spoke of the Kingdom of the Father. The light emitted by 'the Father' is described in Gnostic texts as being stronger than 10,000 times 10,000 suns. 'The Father' had no physical body, but was essentially what might perhaps be called a light-ball, or plasma-ball. Those who were

'saved' would themselves put on 'vestures of light' and become mini plasma-balls and would live forever in a heavenly plasma world.

In the lengthy and well-preserved Gnostic text known as the Pistis Sophia, the following conversation between Mary Magdalene (who in the Gnostic tradition was one of the main disciples of Jesus) and Jesus is recorded:

Maria came forward. She worshipped at the feet of Jesus and said: 'My Lord, be not angry with me, that I question thee ... For thou hast once said to us: "Seek and ye shall find ..." ... My Lord and my Saviour, of what kind are the twenty-four invisible ones, and of what type, or what form are they, or of what form is their light?'

Jesus answered however and said to Maria: 'What is there in this world that resembles them, or rather, what place is there in this world that is comparable to them? ... Truly, truly I say to you, the twenty-four invisible ones are lighted ten thousand times more than the light of the sun which is in this world, as I have already said to you at another time. For the light of the sun in its true form is not in this place, because its light passes through a multitude of veils of places. But the light of the sun in its true form, which is in the place of the Virgin of the Light, is lighted ten thousand times more than the twenty-four invisible ones and the great invisible forefather and also the triple-powered God, as I have already said to you at another time.

'Now at this time, Maria, there is no kind in this world, nor light, nor form, which compares with the twenty-four invisible ones, but yet a little and I will take thee with thy brothers, and fellow disciples to all the places of the height ... And you will look forth upon the whole world of mankind, and it will become the size of a speck of dust before you as a result of the great distance. ,1

Gnosticism was strong in both Judaism and in Christianity, though we know that it existed in Judaism long before Jesus, so was earlier than the earliest forms of Christianity. We should bear in mind that Jesus was not a 'Christian' but a Jew. 'Christianity' had not been invented yet. It was named later, based upon his sayings, after the Greek word *christos* meaning 'anointed', which was itself a direct translation of the Hebrew word *messias* that we pronounce Messiah, which also means 'anointed'.

The Jewish Gnostics had an esoteric and secret reinterpretation of the Old Testament texts, maintaining that the Book of Genesis was an allegory. Some extremely strange interpretations are put forward in their writings. For instance, they maintained that Noah did not really build an Ark at all, but that he hid inside a glowing light-cloud, which we would call a plasmoid.<sup>2</sup>

The Gnostic texts are full of descriptions of plasma and plasmoids, often in surprising detail. When gathered together from the many texts that we now have (vastly expanded by the discoveries at Nag Hammadi in 1945, the finally edited, annotated and translated texts of which became available at last towards the end of the twentieth century), a whole world of plasma entities is revealed. Gnosticism conceived of an entire Plasma Universe. It seems that ancient seers were able to perceive clearly what we are only now able to demonstrate scientifically and recreate in advanced modern laboratories.

Manichaeanism, founded by a prophet called Mani, once stretched from Europe to China, though it has now vanished. It too was a 'light-religion' describing plasma phenomena, its origins lying partly in the earlier Gnosticism. Gnosticism itself survived as a mass movement until the extermination of the Cathars in southern France during the Middle Ages, and the fading away of the Bogomils of Bulgaria and the Messalians of Slavic Europe at some unknown time, apparently by the sixteenth century.

The most famous example of an intelligent glowing plasma in ancient 'Western' religious literature is probably 'the burning bush' encountered by Moses on the top of Mount Horeb in Sinai. I should point out to all the modern tourists who mistakenly climb Mount Sinai that it is the wrong mountain, Mount Horeb being further south and rarely visited because there is no easy way up it; at its summit is a magnificent Temple of Hathor, whose cult image was the face of a calf. A golden Hathor calf of that temple was the 'golden calf' of the Bible, though no one has realized this yet.

The Moses story is well known to all Christians and Jews, and to Muslims as well (since Muslims are 'Abrahamic' by tradition, and Moses preceded Abraham). The account is to be found in the book of Exodus (3:2), the second book of the Old Testament of the Christian Bible as well as of the Jewish Torah. Moses encountered this brilliantly shining and burning plasma, which spoke to him, and he described it as being like a burning bush that was however not consumed by its own flames. In other words, it was not a real bush but was round and 'burning' as if it were a bush, which is the only way a person of that early pre-scientific time could hope to describe it.

The voice may have been audible to the ears or it may only have been 'mentally audible' (telepathic). Although many deeply religious people who do not necessarily study the texts carefully believe that the burning bush was 'God', or Jehovah, the text is not clear on that point. It says actually that 'the Angel of the Lord' appeared to Moses as a burning bush, not that

the Lord himself appeared to Moses. That is very different! In one of the translations, the English Standard Version, we are told: 'And the Angel of the Lord appeared to him [Moses] in a flame of fire from the midst of a bush ...'<sup>3</sup>

The Septuagint is also confused, because although the apparition is said to be 'the Angel of the Lord', the Lord himself is also apparently watching, and when he sees Moses approaching, he too cries out from the bush himself and calls Moses by name, telling him not to approach closer. So who was it, the Angel of the Lord or the Lord himself? As I say, this is not at all made clear by the text.

This confused story seems to have only one reliable element to it, in the absence of the original Hebrew text, which was lost more than two thousand years ago, and that element is the bush-like burning apparition that 'did not consume itself' but continued to burn apparently without any fuel. In other words, this seems to be a description of an encounter with a glowing plasma ball, or blazing plasmoid, which spoke. And encounters with such apparitions are to be found throughout the religious and sacred literatures of many countries over the millennia, and are also recorded by the more mystically inclined ancient Greek philosophers.

In fact, what is described as happening to Moses is something that has happened countless times to sages, shamans, meditators, yogis, and holy men throughout the ages. An analysis of many of these encounters could shed a great deal of light upon the interactions throughout history between 'spiritual' plasma forms of beings, whether 'higher entities' or deceased persons.<sup>4</sup>

Figure 5. The Angel of the Lord speaks to Moses from the Burning Bush (top left corner). The snake may refer to the transformation of Moses' staff. This image is from an illustrated Latin Bible of 1567.

The great scholar of Judaism, Gershom Scholem, argues that the figure known as Moses (whether mythical, real, or partially real and partially mythical) seems to have been responsible for changing the religion of the Jews into a monotheistic religion, and for treating the earlier Jewish ideas as 'heretical'. But those 'heresies' persisted nevertheless for centuries, and today we describe them as 'Gnostic Judaism'. They were in turn taken over by 'Gnostic Christianity', which was as ferociously persecuted by the Roman Catholic Church (self-styled 'Christian orthodoxy') as the Pharisees were by the Sadducees (self-styled 'Jewish orthodoxy'). But now we turn away from Moses to consider another early Jewish prophet, Enoch.

Here is an encounter of the prophet Enoch with divine radiance as recounted in the Book of Enoch, in which we must note the mention of an entity called 'the Great Glory', which is reminiscent of 'Angel of the Lord', who was called 'the Glory' by the Samaritans:

And the vision appeared to me thus; behold in the vision clouds invited me ... I drew nigh to a wall which is built of crystals and surrounded by a fiery flame: and it began to affright me. And I went into the fiery flame and a flaming fire surrounded the walls of the house, and its portal blazed with fire. And I entered into that house, and it was hot as fire ...

And lo! There was a second house, greater than the former, all the portals of which stood open before me, and it was built of flames of fire ... And its floor was fire, and above it were lightnings ... and its ceiling also was flaming fire. And I looked and saw therein a lofty throne ... as a shining sun ... And from underneath the great throne came streams of flaming fire so that it was impossible to look thereon. And the Great Glory sat thereon and His raiment shone more brightly than the sun and was whiter than any snow ... A flaming fire was round about Him, and a great fire stood before Him ... And until then I had had a veil on my face, and I was trembling. 5

Later Enoch also relates: 'And they took me away to a place where there were forms like flaming fire, and when they wished they appeared as men.' In other words, he is describing higher beings who normally had the forms of plasma entities, but who could take on human form for interactions with humans. It should be noted that the Book of Enoch is an ancient Jewish work, dating from before the time of Jesus, which clearly discussed divine beings capable of incarnating as men. The Book of Enoch is regarded as a canonical work of scripture by the Ethiopian Orthodox Church, which is one of the earliest Christian churches.

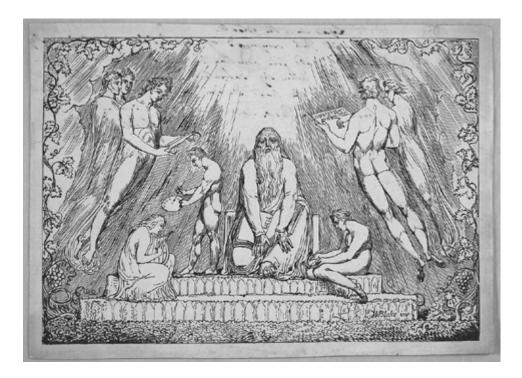

Figure 6. William Blake's 1807 lithograph of Enoch in Heaven.

The Platonic philosopher Damascius (458–550 AD) believed that the human spirit was 'a radiant body filled with heavenly radiance, a glory that

streams through its depths, and lends it a divine strength; but in lower states, losing its radiance, it is dirtied, as it were, and becomes darker and darker and more material.'6

The philosopher Philoponus of Alexandria (490–570 AD) believed that this spirit was a higher soul attached to the basic soul. In other words, he believed, as did the ancient Egyptians, in more than one level of soul for each person. He wrote: 'There is, moreover, beyond the soul another kind of body, that is forever attached to the soul, which they call radiant or starlike ... (and) it forever keeps its radiant body, which is of an everlasting nature.'

The Jewish Gnostic treatise discovered at Nag Hammadi in 1945, *The Apocalypse of Adam*, <sup>8</sup> features Adam speaking to his son Seth and saying that before he and Eve were thrown out of the Garden, they had gone about in a radiant and glowing condition. He says that when the descendants of Seth return eventually from Earth to the divine regions, they will all become clouds of great light. And he also speaks a great deal in general about radiant clouds of glory.

In the early Christian Gnostic text discovered at Nag Hammadi in 1945, entitled *Marsanes*, <sup>9</sup> the narrator says: 'The third shape of the soul is spherical.' There is considerable unanimity amongst many of the mystical texts of antiquity that men and higher entities alike have souls that are radiant and glowing spheres. Men who become too attached to Earth cease to radiate light and go dark, thus resembling the fallen angels who have become demons of darkness.

Another Nag Hammadi Gnostic text, *The Paraphrase of Shem*, <sup>10</sup> is full of descriptions of heavenly 'clouds of fire', 'garments of light', 'luminous spirits', 'images of light', 'the power of the restless fire', 'the light of spirit', 'the exalted, infinite light', 'clouds of power', 'clouds of light', 'the cloud of silence which is a majestic fire', 'garments of fire', 'a power of fire and light', 'thought that comes forth from the light', and says: 'The righteous spark is the cloud of light that has shone in your midst.'

Ideas such as the garments of light and fire seem as if they might allude to the presence of plasma in and around the human body, which we will return to in the final chapters of the book.

One of the most famous and impressive of the Nag Hammadi texts is *The Apocryphon of John*, <sup>11</sup> which is dated to the early part of the third century AD. It is full of descriptions of 'luminous clouds'. Such a luminous cloud is mentioned in particular in the text's alternative story of Noah. The text says that the story of Noah and the ark 'is not as Moses said' [Moses was here presumed to be the author of the Book of Exodus], but the true story is very different. We are told that Moses was wrong in saying of Noah that 'He hid himself in an ark' because he had been warned that the flood was coming. The text insists that it was 'not Noah alone', but 'also other men'. And we are told that 'They went into a place and sheltered themselves within a luminous cloud.'

The text also speaks of angels as being 'lights'. However, it is not only the good entities, but also the bad entities who reside in luminous clouds. The Gnostic name for the Devil is the Chief Archon, also called Samael, Yaldabaoth, and Saklas (which means 'the Fool'). The text tells us that the Chief Archon 'created for himself an Aeon [a special place] that burns with a luminous fire, the one in which he exists now'. (The Gnostics altered the meaning of the ancient Greek word  $ai\bar{o}n$  and used it in their own peculiar way. The term 'Aeon', the Latin form that we use in English, occurs constantly in their texts.)

In other words, the Devil himself lives in a fiery plasma cloud. So consequently, both the powers of Good and the powers of Evil dwell in or consist of plasma clouds. The War in Heaven is thus a war between good and bad plasmas, and the extent to which they can recruit humans on their respective sides is assumed to have a bearing on how long the world will last before it reaches its ultimate climax when the final reckoning occurs. At that time, the 'elect' amongst humanity, who have remained good despite all temptations, will rise up to the Kingdom of Light, and the powers of Darkness will be annihilated.

Humanity has been inundated with such accounts of what we would call, using the terminology of science, divine plasma entities, for millennia, but most people have tended to disregard them as either fantasies, or the enthusiastic reveries of people who were not entirely sane. But they constitute massive evidence of phenomena experienced by sensitive and meditative persons in all cultures round the world. Now at last science has

caught up with mysticism, and modern physicists are seriously suggesting that intelligent plasma beings can exist after all.

Are plasma entities to be regarded as helpful or harmful to us? The traditions are explicit that they can be both. But the helpful ones are radiant with light, whereas the harmful ones are dark and perverse, as their light has been contaminated and made obscure with the dirt of corruption. It is time that humans were given a proper briefing on this 'material world of the spirit'.

This is a short survey of some of the myriad descriptions of light phenomena in ancient religions. Of course, key events in the New Testament, such as the Transfiguration – where Jesus appeared radiant in glory and the Pentecost – where tongues of light appeared hovering over the heads of the Apostles – also seem suggestive of plasma and plasmas.

## Aristotle's pneuma

Although the word 'plasma' was only coined in 1928, some thinkers in the ancient world had an idea of it. For reasons of space, I am going to confine myself to two examples where the ancient examples are startlingly close to our modern ideas.

Something very strange was going on in the fourth century BC, and I call it Aristotle's Anticipation of Plasma Physics and Bioplasma. Aristotle (384–322 BC) is often thought of as a rather dry character, who wrote profound philosophical tomes that only very serious-minded people try to read. However, the real Aristotle was very different; he published two books of poems – and three of his poems actually survive. Another thing is that he freed all his slaves, some during his lifetime and all the rest in his will.

One of the reasons he had to flee Athens for his life when he was sixty-two years old is that he had written an ode to his deceased wife, and the high view he had of women was considered offensive to the male chauvinists of ancient Athens, who liked to keep women in their place, i.e., either on their backs or sitting at the spinning wheel, and not allowed out of the house without chaperones. Furthermore, Aristotle was that horrible and despised thing, a foreigner; he was born in the north of Greece and he was a resident alien in Athens.

Significantly for this volume, Aristotle was the first Western thinker to postulate the existence of a rarefied form of matter entirely separate and wholly different from physical matter. He named it *aithēr*, which we spell 'aether' or 'ether' today in English (and the old-fashioned English spelling was 'aethre', though no one uses that spelling anymore). Since physical matter was then conventionally spoken of as made of 'earth, air, fire, and water', Aristotle called his new form of matter 'the fifth element'. In Latin this is *quinta essentia*, which is the origin of our English word 'quintessence'. This was the first time in recorded history that plasma had been anticipated. I am still struck today by the startling boldness of Aristotle, who also questioned the nature of matter in such a fundamental way.

Aristotle's aether was viewed by him as a form of matter that existed in the pure state only in what today we would call 'outer space', but was then called 'the region above the moon'. Aristotle thus anticipated our modern knowledge of plasma in physics. If he were alive today, Aristotle would not be surprised to be told that the Sun was entirely composed of plasma and that the space between the Sun and the Earth was filled with a solar wind made also of plasma. For this is what he had predicted.

Aristotle went much further than only proposing that there was a higher form of matter. He actually proposed that each living physical body had a corresponding aetheric body, or what is now called by some modern scientists a 'bioplasma body'. (We will hear much more about bioplasma bodies later on.)

His writings on this subject are mostly lost and survive only in fragments. Some of those lost writings were dialogues rather than treatises. It is little known today that Aristotle was as famous for his dialogues in his own day as was Plato. But such are the vagaries of what survives and what does not that not a single one of Aristotle's dialogues survives in its entirety, and those fragments that do survive as quotations by Cicero and others are tantalizing in their brevity. We are somewhat luckier with what are called the 'testimonia', which means the descriptions of, rather than the quotations from, the lost dialogues. But even so, we get only a glimpse of Aristotle's discussions of his theories of a fifth element.

It is worthwhile giving a bit more detail about what Aristotle believed, since few classical scholars have made a proper study of this aspect of his

ideas. The scholar who has advanced a study of this subject the most is Professor A.P. Bos of the Netherlands, who publishes most of his writings in English. He has 'cracked the code' of many of Aristotle's ideas, which have been only partially preserved, and this has taken him decades. Much of the information that made this possible is to be found in the philosophical dialogues of Cicero, in the writings of Philo, of Clement of Alexandria, and in a fascinating essay by Plutarch of the first century AD entitled 'On the Face which Appears in the Orb of the Moon'.

The original key book by Bos in which he began to discuss these questions is entitled *Cosmic and Meta-Cosmic Theology in Aristotle's Lost Dialogues* (1989), but Bos has worked steadily on the subject since that time and continues to find out more and more about the subject.

In the book just mentioned (<u>here</u>), Bos tells us of Aristotle's fifth element:

This new element is according to Aristotle a soma [physicality] and can therefore be counted among the 'natural somata' [plural of soma]. But it does not share the hylē [substance] of the four earthly corpora [elements]. For this reason it is described as ahylon [possessing no hylē, or physical body], as a kind of 'immaterial matter' ... While maintaining his belief in the divinity of the celestials [divine beings] and their eternal existence, Aristotle bases this stance on his own new theory of the fifth element ... the celestial spheres [consist] of the divine fifth element.

Aristotle also believed that the divine beings as well as human spirits were made of the fifth element, and that when we die our spirits made of the fifth element return to the world of the fifth element, which he conceived of as being somewhere above the atmosphere. And of course he viewed all stars and the Sun as being made of aether. And he distinctly postulated, under the name of *pneuma*, the existence of a form of the fifth element within animal and human bodies as an animating principle, for the details of which see the footnote. These beliefs of his later had an influence on the fundamental concepts of Christian theology, especially the Gospel of John. 12

I won't go into more detail here about these ancient ideas, as fascinating as they are, but I want readers to know that more than 2200 years before Crookes discovered his 'fourth state of matter', Aristotle had predicted it. That is more than a footnote to history, it is an extraordinary fact.<sup>13</sup>

I say Aristotle was the first Western thinker to suggest such a thing, because the Chinese philosophers of Daoism never accepted a dichotomy between matter and spirit. Such a dichotomy is entirely a Western

phenomenon. The Chinese have always maintained that 'spirits' were made of a very special rarefied kind of matter like a mist. So deep do these concepts go in Chinese thinking that it is very difficult to find a Chinese person alive today who does not 'believe in ghosts' implicitly. They always seem to have believed that very wise people never really died, but that their physical forms were transmuted into what they call *xian* (spelled hsien in the old spelling), which is pronounced similarly to 'shenn'.

These wise, deceased shamans were conceived of as living in remote mountains and forests and flying through the air and the clouds with the greatest of ease, thinking profound thoughts and enjoying the delights of heavenly contemplation. As for most other people, they became ghosts, which were a much lower grade of being, but also made of the same rarefied semi-matter. Psychologically disturbed ghosts were dangerous, and they haunted people and places. The female ones were the most dangerous of all, and were known as 'fox fairies'. They would lure men to their doom and destroy them like vampires.

A very large proportion of Chinese fiction over the ages has taken the form of ghost stories, because of the Chinese preoccupation with rarefied entities made of what we today would call plasma. Anyone who enjoys atmospheric ghost stories should read those by the most famous Chinese author of them, Pu Songlin (1640–1715), one of my favourite authors, and whose house I have visited in Shandong Province.

However, living in the Western world as we do, I do not propose to write a history of the Chinese beliefs in ghosts through the ages, or even the various texts that discuss such matters, or how they also anticipated modern plasma in a somewhat vague manner. I thought it important to mention it, for the history of the world does not consists solely of the history of the West. But I will pass over the Chinese sources, because it would require a lengthy account indeed to explain the differences between Chinese and Western thinking, which is a vast chasm of incomprehension, alas, and impossible to explain in a short space. Suffice it to say that a plasma world would be less surprising to the Chinese than to Westerners.

As for genuinely proto-scientific speculations anticipating plasma, I am not aware of the Chinese having produced any. It was the Daoists (old spelling: Taoists) who promoted these ideas. They were well aware that the physical sense of sight was incapable of perceiving certain forms of matter,

which were invisible. Liezi (Lieh Tzu, fifth century BC) says that rarefied matter 'eludes the senses of sight, hearing, and touch, and is therefore called by the name of Yi.' The Chinese character for this Yi is the same as is used in the title of the famous divination book called Yi Jing (old spelling: I Ching, 'The Book of Change'), and therefore also has the meaning of 'change', or one might better say, 'what changes'.

Laozi (Lao Tzu, uncertain whether sixth or fourth century BC), the founder of Daoism, speaks of the invisible primaeval matter in this way: 'The likeness of things unseen: the form of that which is without body.' And he says: 'What you cannot see by looking at it is called Hi (rarefaction, or vacancy) ... That which eludes the sense of sight is called Hi.' He also says that Hi and Yi are the same.<sup>14</sup>

However, we must resist the temptation to investigate Chinese Daoism further, as it is an endless subject. The point to note here is that Laozi attributed bodiless form to what we now call plasma. He was thus not simply speaking of some primaeval sludge invisibly sloshing around us like an undifferentiated sea, but he was aware that it must be structured. One could stretch a point and say this is the ancient prehistory of the concept of a plasma crystal!

Before we leave ancient teachings on plasma, I want to return briefly to recent discoveries, which we discussed in Chapter 4, that plasmas precipitate matter and that matter is also otherwise precipitated out of 'nothing'. These recent scientific discoveries also resonate with ancient wisdom.

Various religions from different parts of the world suggest the creation of matter as coming from 'speech'. In Christianity, we are told: 'In the beginning was the Word (*logos*), and the Word was with God and the Word was God ... all things were made by Him and without Him was not anything made that was made.' In the earliest form of Hinduism, the Universe was said to be created by Brahmā, who is an all-embracing universal spirit. He opened his mouth to speak and he spoke the four Vedas, which are the ancient collections of sacred hymns that the Aryans brought with them from Iran when they invaded India from the West circa 1500 BC. The Vedas are considered the most sacred of the Hindu scriptures, and are written in an archaic form of Sanskrit known as Vedic.

In ancient Egypt, the god Ptah was said to have created the world by his speech. The wall texts of the Tomb of Rameses VII in the Valley of the Kings state of the Sun: 'His speech is light.' And in the ancient Egyptian text known as the *Book of Caverns*, which was preserved in the Transverse Chamber of the Osireion at Abydos, we read of the Sun, whose name is Re: 'Re speaks to them through his light.' The ancient mystical concept of the Logos in Johannine Christianity also suggests that 'the Word' (of God) was light.

Sacred speech is essentially something that emerges from something else, just as our breath is emitted from us into the air around us. It seems that the ancient peoples when referring to the creative speech of the primal god were trying to convey the concept of expelled, structured breath entering into a surrounding medium but retaining its own form, and thus constituting matter.

Since we now know that the Universe is a seething ocean of plasma, and as it has now been proven that plasma makes dust, and that dust is matter, it is legitimate to consider that the 'material Universe' has been extruded from and created by the universal plasma. In other words, the 1 per cent is the creation of the 99 per cent. And looked at from that perspective, the traditional religious views of the creation of matter are justified. For the spontaneously formed dust and the baryons are the building blocks of the familiar world around us.

But if we look back to our ultimate origins in the world of physical matter, we are all children of plasma. The Egyptians would say we are 'the progeny of Ptah', the Christian view is that we are 'the children of God', and a Hindu might say: 'We are all the creation of the great universal spirit, Brahmā.' The other early creation legends of 'in the beginning was undifferentiated chaos' or as the ancient Egyptians said, the goddess Nut, who was a great cosmic sea, and the Torah and the Old Testament that speak of 'the waters', are all effectively saying the same. On this view, all physical matter did indeed emerge from the vast universal sea of plasma.

## Kristian Birkeland's Miraculous Discovery

Kristian Birkeland (1867–1917) is famous in Norway, and his picture was until recently on their 200 kroner banknote, so between its appearance in 1994 and its withdrawal in 2018, the Norwegians were reminded of him every day when they went shopping. He was a very brave man, who spent years freezing in the Arctic wastes in the north of Norway making detailed observations of the Aurora Borealis, or Northern Lights as they are often called. He concluded that the Northern Lights (and there are southern ones too at the South Pole, known as the Aurora Australis) must be caused by streams of charged particles pouring in from the Sun towards the Earth's poles. These particles then glow and cause all the beautiful lights.

This theory caused the utmost outrage, and astronomers all over the world called Birkeland a madman. Did he not realize that space was empty? Charged particles could not pass through empty space! And so instead of facing Birkeland's carefully presented evidence, the world's 'astrophysical community' stuck with their insistence upon empty space and decided that Birkeland was a crank. He died unrecognized in 1917. His theories about the Aurora were not proved true until spacecraft verified them in the 1960s. Because Birkeland is one of my heroes, I was active in certain minor ways in helping to facilitate the 2017 Oslo Birkeland Centennial Conference to celebrate his great scientific work.

Kristian Birkeland appeared until recently on the Norwegian 200 kroner banknote. Image reproduced with the kind permission of the Bank of Norway. Copyright by Norges Bank/ artist Sverre Morken. This banknote was legal tender in Norway between the years 1994 and 2018.

Before we go into the subject of the solar winds and the Birkeland Currents, it is important to have a very brief history of how their existence came to be recognized. And that means knowing how and when the polar aurorae came to our attention and the early attempts to understand them. Naturally, it is the peoples of the North who saw them all the time, and a thirteenth-century Norwegian saga called *The King's Mirror* (*Kongespeilet*, dated to AD 1220–1230) contains a reference to them. It mentions 'those lights ... which the Greenlanders call the northern lights'. <sup>1</sup>

Although the Northern Lights are rarely seen so far south as Greece or Rome, they were certainly witnessed by Aristotle, who described them in his lengthy book *Meteorology* as:

burning flames in the sky ... we often see a burning flame of the kind one sees when stubble is being burnt on ploughland ... Sometimes on a clear night a number of appearances can be seen taking shape in the sky such as 'chasms', 'trenches' and blood-red colours ... the upper air condenses and takes fire and ... its combustion sometimes produces the appearance of a burning fire.<sup>2</sup>

It has been suggested that Aristotle may have seen the Aurora Borealis twice, in 349 BC and again in 344 BC.<sup>3</sup> We must remember that Aristotle was born and grew up in the north of Greece, and lived for some years in Macedonia as an adult as well, thus having spent much of his time at a higher latitude than Athens. Aristotle theorized that a vapour rose from the Earth that collided with the Sun's fire above the atmosphere, where it was

ignited, and thus produced the colourful flashes in the sky. He stated that there was a layer of a strange kind of 'fire' encircling the Earth above the air, thus clearly anticipating the later discovery of the ionosphere by Balfour Stewart in 1887, 2,119 years after the death of Aristotle. The quotation from Aristotle in the footnote is truly astonishing in its anticipation of the nature of the ionosphere.<sup>4</sup>

Aristotle may have been influenced in his thinking by Homer. In the *Iliad* (Book 2, 412 and Book 3, 277–9), Homer describes the chief god Zeus as aether-dwelling (*aitheri naiōn*), meaning that he resides in the blazing and dazzling aether of the heavens above the sky. Much is made of this by the first-century AD Homeric commentator, Heraclitus the Grammarian (not to be confused with the famous philosopher of the same name, who lived centuries earlier). In his work *Homeric Problems*, he cites this Homeric concept specifically in relation to the Aristotelian tradition. He suggests that the name of Zeus may derive from the word *zesin*, which means 'boiling', because of the intense fiery heat of the aether. He mentions Aristotle's followers saying of aether that it is 'distinct from fire' and 'they regard it as a fifth element'.<sup>5</sup>

It should be noted that Aristotle made an intensive study of the variant texts of Homer and even travelled to the island of Ithaca to obtain a copy of the Ithacan version of the *Odyssey*, from which he compiled his own edition of the epic. It was well known in antiquity, though it is now lost. Indeed, it was Aristotle's editions of Homer that Alexander the Great, his pupil, carried with him on his conquests and kept under his pillow every night, as recorded by contemporary historians.

The aurorae had been witnessed in Greece prior to Aristotle ('a fiery body of great size like a burning cloud was observed in the heavens. It did not remain at rest, but moved in various directions ... [with] violent swaying ...'), but the earliest surviving written account of this phenomenon is found in the Life of Lysander (12, 4) by Plutarch (AD c. 46–125), four centuries after the time of Aristotle.<sup>6</sup> Aristotle's text is therefore the earliest surviving text in the world referring to the Aurora Borealis, and of course he did not merely describe the aurorae, he attempted to explain them scientifically as well.

Both Seneca (4 BC–AD 65) in his Natural Questions (I, 14, 1),<sup>7</sup> and Pliny (AD 23–79) in his *Natural History* described the Northern Lights.<sup>8</sup> But after that, apparently nothing was published about them for approximately 1500 years (the Norwegian saga mentioned earlier being of course an oral saga, not a publication).

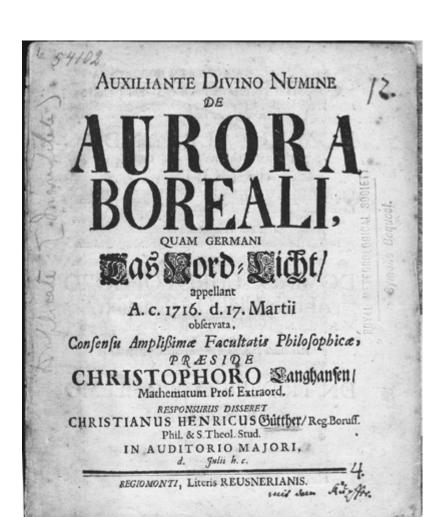

The astronomer Tycho Brahe (1546–1601) mentioned them in passing, the astronomer Johannes Kepler (1571–1630) witnessed and described them, and Galileo (1564–1642) witnessed them at Venice in 1621. It was apparently Galileo who introduced the name Aurora Borealis, in a publication of 1616, though in a descriptive sense rather than with an intention of naming them, and it is not known whether he had actually seen them yet. It is thus not clear whether Galileo should be credited for naming the Aurora Borealis, or whether that honour belongs to Pierre Gassendi, who is usually credited with it, and who had obviously read Galileo and seen his descriptive reference. Perhaps we should split the credit between them. In 1619, Galileo attempted to explain the Northern Lights, with similar ideas to those of Aristotle.<sup>9</sup>

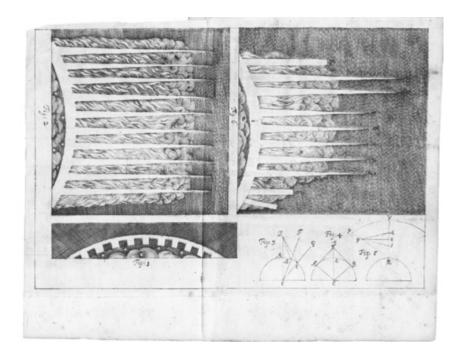

It was in the same year of the Venice auroral display, 1621, that the French scientist, scholar and philosopher Pierre Gassendi (1592–1655) formally used the name 'Aurora Borealis' to refer to the Northern Lights, in honour of the ancient Greek goddess of the dawn, Aurora. Gassendi was a keen observer of the heavens, including studying sunspots and observing the transit of Mercury across the Sun. He even successfully predicted an eclipse in 1654. He was only twenty-nine years old when he 'named' the Aurora Borealis, despite the fact that he had apparently not then seen the Northern Lights personally. It is believed he came to know of them through his early friendship with the astronomer Joseph Gaultier de la Vallette (1564–1647), and by reading the recent accounts of them by Galileo.

In 1640, Spanish colonizers in Chile recorded a large auroral display in the Southern skies, which lasted from the beginning of February to the end of April, but this remained only a locally known matter in Chile for the next 142 years, for it was only in 1782 that the Chilean Jesuit priest Juan Ignacio Molina SJ (1740–1829) became the first European to report in print this and other subsequent Spanish accounts of the existence of a southern aurora, which was otherwise unknown in Europe.

In 1716, a German professor of both theology and mathematics named Christoph Langhansen (1691–1770) published a pamphlet in Latin at Königsberg entitled 'De Aurora Boreali Quam Germani Das Nord-Licht Appellant' ('Concerning the Aurora Borealis, Which the Germans Call the Northern Lights'), containing an impressive fold-out engraving of particularly bizarre auroral phenomena, which I have reproduced overleaf, along with a scan of the title page. I bought a fragmentary copy of this booklet, only the first ten pages of the extremely rare 28-page work, but fortunately the illustration was present.

The work appears to suggest that the Aurora Borealis is a spiritual phenomenon, which is hardly surprising, in that the author was not only a theologian but a practising preacher, who was five times a rector of a Lutheran church. The author refers to numerous publications by earlier authors, including Girolamo Cardano, Philippe de la Hire, Valentine Weigelius, Giovanni Domenico Cassini, Giovanni Battista Riccioli, Schmieder [unknown which Schmieder is meant], and René Descartes. Frankly, this suggests that there may have been a great deal of discussion of the aurorae going on during this time of which I have no knowledge, although it would certainly be an interesting subject to investigate for someone who cares to go into the matter in greater depth, to see what all these people were saying. This is a wonderful subject for somebody's future PhD thesis.

Figures 7 and 8. The title page and the fold-out engraving of the 1716 publication about the Aurora Borealis by Christoph Langhansen, from my imperfect copy of this rare work.

A forerunner of Kristian Birkeland whose publications have been largely forgotten is an early French scientist, who seems to be remembered today only in France itself. His name was Jean-Jacques d'Ortous de Mairan (1678–1771). He was active in many fields of science, but even amongst the French it seems to be little known today that he was the first person in the history of science to suggest that material from the Sun was not only being transmitted across space to the Earth, but actually deposited within the Earth's atmosphere.

His magnum opus on this subject was a very lengthy book with many illustrations entitled *Traité Physique et Historique de l'Aurore Boreale*, published in 1735. <sup>10</sup> This material was widely circulated in Europe at the time and the book was translated into German in 1753. <sup>11</sup> De Mairan stated that material from the solar atmosphere crossed space, reached the Earth, and caused the Aurora Borealis in our own atmosphere. He claimed that the atmosphere of the Sun was a light and tenuous fluid, which 'reached as far as the Earth'. This is a surprisingly accurate guess for a man in the eighteenth century, since it is reasonable to describe plasma flows as 'a light and tenuous fluid'. His words, translated, are: '... the matter composing this [solar] atmosphere coming to meet the upper parts of our air ... falls into the terrestrial atmosphere at more or less depth ...'

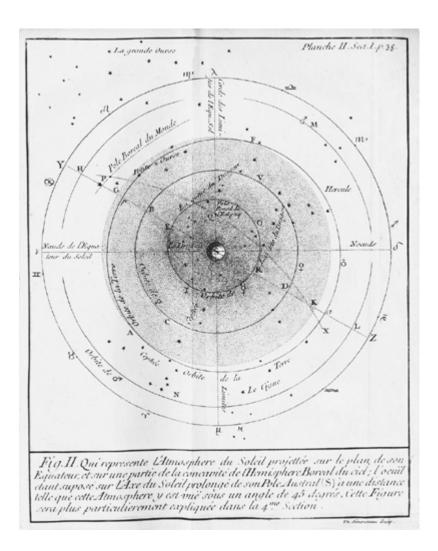

Figure 9. This engraving of 1733 shows the 'Sun's atmosphere', as conceived of by de Mairan, extending from the Sun (shown in the centre and labelled with the capital letter S) to the orbit of the Earth (Orbite de la Terre). The solar atmosphere is represented in the drawing by the shaded portion, which is largely comprised within the orbit of the Earth. On p. 22 of his book, de Mairan describes the solar atmosphere as being 'a spheroid which has been flattened at its edge into the form of a circular disc'. De Mairan's concept of the solar atmosphere that reached the Earth partially arose from the researches by his Swiss contemporary Nicolas Fatio de Duillier (1664–1753, whom he calls simply 'Fatio') concerning the distance between the Earth and the Sun.

In his own caption de Mairan says: 'This represents the atmosphere of the Sun. It is projected on a map of the Equator and on one section of the concavity of the Boreal hemisphere of the sky. The centre is superimposed upon the axis of the Sun projected onto the astral Pole at such a distance that this atmosphere is viewed at an angle of 45°.' (From: Jean-Jacques d'Ortous de Mairan, *Traité Physique et Historique de l'Aurore Boréale (Physical and Historical Treatise Concerning the Aurora Borealis*), Paris, 1733, the second folding plate following p. 32.)

Since de Mairan first announced these ideas in 1731 to the Royal Academy of Sciences in Paris, he anticipated Kristian Birkeland's first announcement of similar ideas, which also took place in Paris, in 1900, by

169 years. De Mairan also published many illustrations, including some spectacular ones of the aurorae. He may probably thus be credited with being the first predictor of what we now call the solar wind.

In 1767, Knud Leem (1697–1774) published a book in Danish entitled (in translation) *An Account of the Lapps of Finmarken*. In it, he described how the Lapps of Lapland in the far north go hunting with guns for foxes by the light of the Aurora Borealis. He said: 'This kind of sport (!) the Lapps pursue at night when the moon is up, or when there is an Aurora Borealis, which in that country, during the winter nights when the air is clear, is as intense as if the sky were on fire, and which, in a manner, shines like the most brilliant moonlight.' Leem even published an engraving of the Lapps doing this, depicting the auroral streaks in the sky behind them providing the necessary illumination. <sup>12</sup> This and the Langhansen illustration of 1717 are surely two of the earliest depictions of the Aurora Borealis ever published.

Figure 10. Knud Leem's drawing of 1767 showing the Lapps of Lapland hunting foxes on the ice at night, by the light of the Aurora Borealis.

In 1745, long before Molina's publication, the mariner Antonio de Ulloa y de la Torre-Giral (1716–1795) witnessed the southern aurora from his ship as he rounded Cape Horn, but his reports of this appear to have remained oral ones amongst sailors until long afterwards. In 1770, Captain James Cook (1728–1779) observed the southern aurora on his first voyage to Australia. But this seems not to have been reported in print at the time and to have remained recorded only in his log. In 1773, Captain Cook observed the southern aurora again on his second voyage to Australia, and he gave the Southern Lights the name of 'Aurora Australis'. Cook died three years before Molina's publication publicly reporting the existence of the Southern Lights.

In 1812, the English scientist Sir Humphry Davy (1778–1829) published his opinion, in his essay 'Of Electrical Attraction and Repulsion, and Their Relation to Chemical Changes', <sup>13</sup> that:

The coruscation [flashing and glittering] of the Aurora Borealis, and Australis, precisely resemble strong artificial electricity, discharged through rare air ... the Auroras may arise from a discharge of electricity, accumulated in the atmosphere near the poles.

In 1845, inspired by and referring back to Sir Humphry Davy, Baron Karl von Reichenbach (1788–1869) published his theory (in German, published in English in 1850) that the Aurora Borealis 'appears to be nothing else than an electric phenomenon, caused by the magnetism of the earth'. <sup>14</sup> He had constructed terrelles, meaning small magnetic spheres as miniature models of the Earth, which had generated lights at their two magnetic poles. <sup>15</sup> In this, he anticipated by many decades Kristian Birkeland's more sophisticated and famous experiments in Norway; Birkeland also constructed terrellas to replicate the auroral effects with miniature spheres containing an electro-magnet in their interiors.

In 1862, the Swiss physicist Arthur-Auguste de la Rive (1801–1873) published a paper concerning both the Northern and the Southern Aurorae. <sup>16</sup> He had been studying the aurorae since 1849.

Nearly a century passed after Molina's publication before any major developments concerning a sound understanding of the aurorae appear to have taken place, however. In 1878, Karl Selim Lemström (1838–1904), a Finnish geophysicist of Swedish extraction, published an article in Swedish in a Finnish periodical based upon his extended observations of the Northern Lights in Scandinavia.<sup>17</sup>

In his article, he reported that as a result of his studies over a considerable time, he had come to the conclusion that the auroral phenomena varied with the sunspot cycle of eleven years. That is a cycle during which the Sun goes from having a maximum of sunspots to having a minimum of them, and back again. No one knows why it does that. (At the time of writing, we are at the minimum.) He said that in his opinion, the aurorae were caused by electric currents in the Earth's atmosphere, which were stimulated by what he called 'heat rays' coming from the Sun. Electric currents were still imperfectly understood at this time, and it was only in this same year, 1878, that Henry Augustus Rowland (1848–1901) carried

out his famous 'Rowland Experiment', which showed that electric current consists of moving charges.

Not knowing about charged particles constituting the electric currents, Lemström was in no position to conceive of electric currents as charged particles actually coming from the Sun. He also still thought that space was empty, which must be why he could only conceive of 'heat rays' coming from the Sun. But Lemström was an important precursor of Birkeland, who took his work very seriously. Lemström published his book *L'Aurore Boréale: Étude Générale des Phénomènes Produits par les Courants Électriques de l'Atmosphère (The Aurora Borealis: A General Study of the Phenomena Produced by the Electric Currents of the Atmosphere)* in 1886.

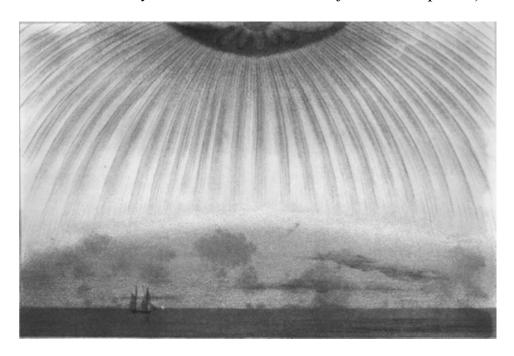

Figure 11. One of the many spectacular colour illustrations of the Aurora Borealis published by Lemström.

The next year after the publication of Lemström's original article, in 1879, the Danish scientist and photographer Sophus Tromholt (1852–1896) noticed when he was visiting Lapland in Norway that the area of sky covered by the Aurora Borealis increased in size and spread southwards when solar activity increased in accordance with the eleven-year sunspot cycle, thus confirming Selim Lemström's assertion of the previous year regarding the clear association of the Aurora Borealis with some kind of

solar influence, correlated with what Lemström called 'changes in the solar surface', i.e., the sunspots.

In 1885, Tromholt published a massive two-volume work in English entitled *Under the Rays of the Aurora Borealis*, containing 150 illustrations. <sup>18</sup> Selim Lemström and his work are mentioned, but the names of Kristian Birkeland and another auroral researcher, the Danish scientist Adam Paulsen, are not. (Paulsen had begun publishing, in French, his important observations concerning the Danish auroral expedition of 1882–1883 in 1884.) <sup>19</sup> Tromholt published a remarkable image of one of Lemström's amazing experiments in producing an artificial aurora shooting up into the sky from a mountain top. That took place in 1882.

Figure 12. Tromholt's depiction of Lemström's experiment of 1882.

A major advance in understanding the electrical nature of the Earth's atmosphere took place three years after this, when in 1882 Balfour Stewart (1828–1887) suggested that there was an entire electrically conducting layer lying above the air and cutting across the Earth's vertical magnetic field, thus being the first person to suggest the existence of what we now call the ionosphere since the time when it had first been suggested by Aristotle.

In 1884, the Danish scientist Adam F.W. Paulsen (1833–1907) published his account of the Danish Polar Expedition of 1882–1883. And in the same year, Adolf Erik Nordenskiöld (1832–1901), a Swedish Finn, published an

elaborate account in French 'Sur les Aurores Boréales' ('On the Aurora Borealis') in a French scientific journal, extracted from his account of the Vega Expedition to the North during the winter of 1878–1879, his original extract concerning the Aurora Borealis having been published two years earlier, in 1882, in Swedish.<sup>20</sup> (The Vega was the name of a ship on which he sailed in search of a Northeast Passage, and on which he got frozen into the ice near the Bering Strait. So he had plenty of time to observe the Northern Lights as he sat there trapped.)

There were many interesting illustrations published by Nordenskiöld. The accounts by Paulsen and Nordenskiöld are extremely important, and although I have their original publications (including even two personally signed by Paulsen), in the interests of brevity I shall refrain from discussing them here. A typical observation by Paulsen is that the electric currents in the atmosphere were strong in the winter and weak in the spring. The conscientious and diligent attempts by these two men to gather information concerning the Aurora were a significant part of the progress in understanding the phenomena.

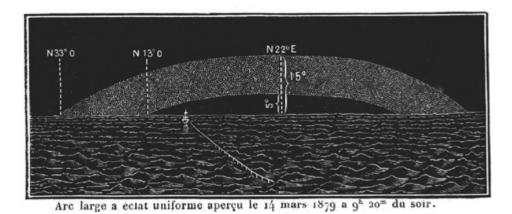

Figure 13. An illustration shown by Nordenskiöld in scientific form, with all the angular measurements precisely given and the *Vega* stuck in the ice.

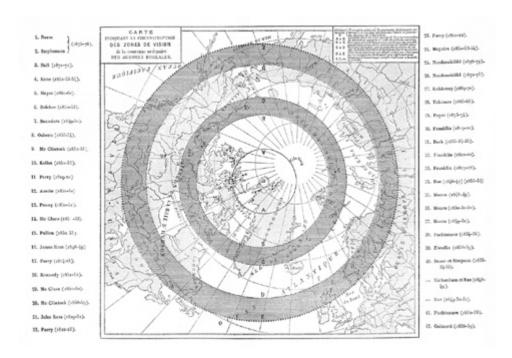

Figure 14. Nordenskiöld's plotting of the regions of the Earth where visibility of the Aurora Borealis had been reported. The North Pole is shown in the centre.

In 1896, Kristian Birkeland, one of the most brilliant scientists of his time, began publishing the great breakthroughs. He hypothesized that the Sun emits rays of electricity ('cathode rays'), which reach the Earth and are 'the object of a suction' by the Earth's magnetic poles, and that there is a correlation between sun-spots, the Earth's polar aurorae, and terrestrial magnetic perturbations.<sup>21</sup>

Birkeland's theories as expressed in 1896 are not well known, as they are mentioned in an exceedingly rare book of his published in French in 1901.<sup>22</sup> I purchased a copy of this book from a book dealer in Paris. It was inscribed by Birkeland to his friend, the famous French scientist Henri Becquerel (1852–1908, winner of the Nobel Prize for Physics in 1903, who discovered radioactivity), and it had thus obviously come from Becquerel's personal library. When I sent an email to Professor Alv Egeland in Oslo, with whom I was then frequently in touch, telling him about this find, he said it was the only one of Birkeland's publications of which there was no known copy in Norway, and he had never seen it, although he had listed it in his bibliography of Birkeland's publications. Alv is the biographer of Birkeland and the world's leading expert on him.<sup>23</sup>

A popular book about Birkeland by Lucy Jago, entitled *The Northern Lights*, was published in 2001, but without footnotes or references.<sup>24</sup> In the Selected Bibliography, Jago does list the 1901 book by Birkeland, so presumably she consulted the single copy of the book that is in the British Library. (It is possible that there are only the two copies in existence today, mine and that one.) Jago begins her book dramatically with a description of events in Finnmark during the 1899 expedition.

As a result of my discovery of the little-known book, I now know that Birkeland formulated his theories of electric currents coming from the Sun many years earlier than had been thought. When discussing these theories of Birkeland, people generally cite his well-known book published in English in two instalments, in 1908 and in 1913, concerning the Norwegian Auroral Polar Expedition of 1902–3, which is widely available today in numerous print-on-demand reprint editions.<sup>25</sup>

But that was the third such expedition, and the book that I discovered concerns his earlier expedition of 1899–1900, and it contains sections on 'Electric Current in the Higher Layers of the Atmosphere' (16 pages), 'Artificial Auroral Bands' (20 pages), etc. It pushes back the timetable of Birkeland's insights considerably from what we had assumed and shows how many more years he laboured at these ideas than had been thought.

As an example of how incorrect dates can spread and become accepted without question amongst the scientific community, we see this statement in Alexander Piel's excellent book *Plasma Physics*, published in 2010:

The space between Sun and Earth is filled with the plasma of the solar wind. This is a flow of charged particles from the Sun, whose existence was first conjectured, in 1908, by the Norwegian physicist Kristian Birkeland ... <sup>26</sup>

But Birkeland first published his 'conjectures' on this subject in 1896, twelve years earlier than Piel believes, and it appears that everyone has been assuming that Birkeland's 1908 book was his original publication of these ideas.

What is important for us here, and what makes Birkeland one of the great heroes of this story, is that having followed in the footsteps of his nearcontemporary Crookes in studying the influence of magnets on cathode rays in vacuums, he conjectured that electron beams from the Sun were being guided towards the Earth's magnetic poles in a similar way. He developed a theory in which energetic electrons were ejected from sunspots on the solar surface, directed to the Earth, and guided to the Earth's polar regions by the geomagnetic field where they produced the visible aurora.

In 1913, Birkeland also may have been the first to predict that plasma is ubiquitous in space. He wrote:

It seems to be a natural consequence of our points of view to assume that the whole of space is filled with electrons and flying electric ions of all kinds. We have assumed that each stellar system in evolutions throws off electric corpuscles into space. It does not seem unreasonable therefore to think that the greater part of the material masses in the Universe is found, not in the solar systems or nebulae, but in 'empty' space. (Quoted on Wikipedia with no reference.)<sup>27</sup>

In 1916, Birkeland was probably the first person to predict successfully that the solar wind behaves as do all charged particles in an electric field: 'From a physical point of view it is most probable that these new solar rays are neither exclusively negative nor positive rays, but of both kinds.' In other words, the solar wind consists of both negative electrons and positive protons and ions. (The quote is from Wikipedia with no proper reference.)

I shall not tell the fascinating story of Kristian Birkeland's life, because that has already been done. Lucy Jago's book about Birkeland the man is a good place to start, and Alv Egeland's book about Birkeland the scientist gives all the other important information one needs. Since Birkeland was such an outstanding genius, both books are highly recommended, as more people need to know about him.

Since Isaac Newton (1643–1727), science and the world had moved towards a material mechanical view of the Universe, picturing solid objects in dead and empty space, held in orbit by gravity. It was a picture to inspire a certain cold wonder, perhaps; gravity was king here. Then Birkeland discovered that electric currents travelling from the Sun were entering Earth's atmosphere. This was a profound and important mystery because electricity can't cross empty space.

It would be another forty years before two scientific geniuses solved this mystery and began to build up a picture of the Universe filled with a web of electrical impulses like a macrocosmic brain.

## The Cosmic Web

In 1933, the Swiss astronomer Fritz Zwicky (1898–1974) was observing the Coma galaxy cluster through the large telescope of the Mount Palomar Observatory in California when he saw an anomaly. He had been making calculations about the galaxy's luminosity and when he compared his observations with his gravitational calculations, he saw that they showed wide discrepancies. So he concluded that unseen matter must exist there to account for the gravitational forces.

He would call this unseen matter *dunkle Materie* (Dark Matter).

And as regards 'dark matter', which would eventually become widely accepted in the scientific community, my position is that one does not need to invent strange new kinds of matter, since it is plasma in different states (gaseous, liquid, solid, etc.) that is in 'the dark mode' and hence invisible to us. This fits perfectly with what we now know about the Universe consisting of 99.9 per cent plasma, bearing in mind too how hard it has been to photograph or even find the Kordylewski Clouds.

But what is important for this book and this chapter is that Zwicky produced evidence to show that space is not empty. Until then 'outer space' had been assumed to be totally empty, consisting of a perfect vacuum, with the exception of the solid orbiting bodies such as planets, moons, asteroids, etc. within the solar system and stars outside it. In other words, no medium was recognized. What happened to Zwicky after his discovery is an example of how blind and stubborn ignorance can hold back our understanding, because of the 'tactics of ignoring' new findings by the self-styled 'Establishment'.

The expulsion of solar material into supposedly 'empty' space was discovered from observation in 1936, three years after Zwicky's discovery,

by the French astronomer Lucien Henri d'Azambuja (1884–1970), while he was using the Observatory Telescope in Paris to look at the fiery material spewed out by the Sun.

After d'Azambuja's discovery of the solar wind, astronomers simply ignored it, as they had ignored Zwicky. Many famous astronomers continued to insist in the most vehement fashion that space was 'empty', and this remained very much the Astronomical Establishment's position. There is nothing like 'establishments' of all kinds to ignore advances and new findings, and try to retain the status quo! And we must never forget that there is a status quo of ignorance, which is precious to the mediocre minds incapable of original thought who make up 'the Establishment'.

During the early 1940s, Zwicky tried to publish further evidence that space is not empty, but publication of his findings was refused by every astronomical and physical journal in the world. The Establishment derided and insulted him and closed ranks to try to prevent his findings from ever being made public. Finally, in 1950, Zwicky was able to get around the boycott of his discoveries only by turning to a biology journal, *Experientia*, which extraordinarily agreed to publish his astronomical findings so that he could somehow get them into print.

It enabled Zwicky's ideas to be circulated at last, even if only in offprints from a biological journal no astronomer had ever seen or heard of. It eventually became clear that the censorship of Zwicky's findings had been illegal, especially considering that his own observatory's committee had acted to ban publication of his findings in all American astronomical journals, which they had no legal right to do. This remains one of the great scandals in American science, and also of Swiss science.

However, the situation has become even worse today, for now it is not only observatory committees that prevent things from being published, but also the organized and combined forces of military, security and corporate power. Most scientists working in astrophysics in America today have signed confidentiality agreements with military agencies, and a large proportion of their work is kept secret under various security classifications, many of which are wholly unnecessary. If the scientists try to release their findings, they can go to jail. Even when some such documents are 'released' in redacted form under Freedom of Information laws, the release is often only technical.

For instance, one relatively uncontroversial scientific report commissioned by the CIA decades ago that I wished to see, as it had been officially 'released' some years ago, can only be seen if you make an appointment and go in person to the CIA archive in Maryland, where you cannot copy it or take notes.

It is remarkable what a short time ago it was that all the world's scientists insisted that outer space was empty. In 1961, the French physicist Alexandre Dauvillier (1882–1979) published his book *La Poussière Cosmique* in France, which appeared in English in 1963 as *Cosmic Dust*. This was certainly one of the first full-length books, and possibly the only one at that date, to devote itself entirely to the subject of cosmic dust throughout outer space. In writing his book, Dauvillier (a distinguished physicist who had worked closely with Louis de Broglie, one of my scientific heroes) felt that he needed to keep explaining and almost apologising for the fact he was writing a book about something that not long before everyone was convinced did not exist.

Here are some of his remarks:

It was thought until recently that cosmic space was absolutely empty ... (<a href="here">here</a>); At the beginning of the century [1900] it was still believed that interstellar space was completely empty and transparent. (<a href="here">here</a>); Twenty years ago [in 1941], the space separating the galaxies was also considered as a complete void. (<a href="here">here</a>); Ten years ago [in 1951] intergalactic space was considered absolutely devoid of stellar or dispersed matter ... The work of F. Zwicky with the large telescope of Mount Palomar showed that intergalactic space is not absolutely empty.' (<a href="here">here</a>)

Unknown until now, there were two other scientists who clearly realized even before Fritz Zwicky did that outer space was not an empty vacuum. This information has come to light very recently from the archives of Sir Fred Hoyle (1915–2001), which have been deposited at St Johns College in Cambridge. Chandra Wickramasinghe, Fred Hoyle's former student and his closest collaborator in his later years, has been going through the unpublished portions of Fred Hoyle's autobiography. I thank Chandra for sharing with me some sections of this material that provide this unique information. And I am grateful to the Estate of Fred Hoyle for permitting their use.

We learn from these unpublished portions that Fred Hoyle and his friend and scientific colleague Ray Lyttleton (1911–1995) had together decided by

1940 that outer space was not an empty vacuum, but was full of 'gas', by which presumably Fred means ionized gas that we now call plasma. However, they went much further than that. What follows are quotes from papers originally written for a book that would be published in 1994.

... [In] 1940 ... Ray Lyttleton and I suggested that the gas between the stars was likely in places to be clumped into much denser clouds than astronomers were then prepared to admit. We also suggested that the gas in dense clouds would be molecular rather than atomic, with molecular hydrogen the dominant component. These perfectly correct predictions never did us much good, however, because they were thought outlandish in their own time and three decades later, when observation had shown them to be correct, nobody remembered what had been said as long ago as 1940. So it goes, I'm afraid.

The thought that molecules, even quite complex molecules, might be present in great quantities within dense clouds of interstellar gas never died away in my mind, although astronomical opinion through the 1950s was so firmly set against the idea that to argue for it in the scientific literature became impossible. Throughout my career I have argued fiercely against the refereeing system practised by nearly all the so-called serious journals. My opinions are admittedly coloured by an intense dislike of being told by referees what I may publish, or not publish. But this is not the whole story. The superficially plausible reasons for maintaining the system are false. The real reason for the existence of the refereeing system is that it provides the majority with a strictly applied censorship over ideas which it does not wish to hear ...

Because in the 1950s the seemingly respectable vehicles of publication were closed to the concept of molecules in space, I turned to the disreputable vehicle of science fiction. My novel *The Black Cloud* was written in an irascible mood immediately following an international meeting of astronomers. The novel had the effect in my mind of connecting molecules in space with life, although by imagining a life-form very different from terrestrial forms, I was unfortunately off on the wrong track.

Fred was not necessarily off track after all, as he realized much later. The sad story of Hoyle and Lyttleton being unable to publish their views echoes the troubles of Fritz Zwicky in the 1940s.

We will return to Fred Hoyle and his contribution to this story in Chapter 11.

However, for all the importance of the work of Zwicky, Hoyle and others, the scientist who probably did most to throw light on 'invisible matter' in space and to prove that space is not empty was Birkeland's fellow Scandanavian, Hannes Alfvén (1908–1995).

The Birkeland Currents were given this name in 1967 in honour of their discoverer, and called then by that name in Alfvén's article 'On the Importance of Electric Fields in the Magnetosphere and Interplanetary Space', which he published in that year.

Alfvén's breakthrough was to follow up Birkeland's speculations by identifying plasma as the medium by which electric currents could travel through space, as he extrapolated what he discovered about the currents running between the Sun and the Earth first to the galaxy and then to whole of the Universe. This breakthrough would lead to both a radical new understanding of the contents of the cosmos and also – by coming to an understanding of the mechanisms by which plasma carried the currents and in turn the effects of currents of plasma – a greater understanding of plasma and its extraordinary properties. By studying Alfvén and his followers, and their discoveries, we can begin to see how plasma in general and the Birkeland Currents in particular are fundamental to the way the Universe works.

Because Alfvén showed that the Universe has this vast network of plasma filaments carrying electric currents, he also showed that the Universe is full of electromagnetic fields. In fact, Alfvén's electric currents in space produce a complex and dynamic interaction of magnetic fields, magnetic currents and electric fields throughout space. The charging of particles in plasmas and space by electromagnetic fields in turn modifies the electromagnetic fields. Whereas once space was thought of as empty, we now know that at a subatomic and quantum level, space is a jungle of plasma, a highly charged, creative ecosystem – with matter in the form of particles being one of the things it creates.

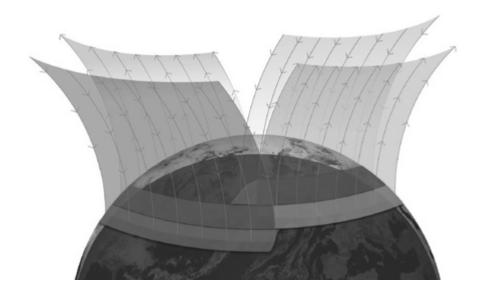

Figure 15. Upward and downward current sheets of flat electric current extending between the Earth and space, discovered in 2017. The pale current sheets show the descent onto the planet of charged particles and the dark sheets show the upwards ascent of charged particles (as indicated by the small arrows). However, it has been well known for many decades that negative current pours into the pole in a stream. It is unclear why this is not also shown, nor is it clear why the current is rising from two opposite quarters of a ring current, how that is happening (what makes it rise?), and what charge these sheets have. (The same? Opposite?) Much more clarity is needed before we can simply accept this picture, which must only be part of a much larger process which is going on and which requires much more investigation. (Image courtesy of European Space Agency).

Alfvén showed that a Birkeland Current is a stream of either negatively charged particles (electrons) or positively charged particles (protons and positive ions) that can travel for immense distances through space (many millions of miles or even billions of miles at speeds not far below the speed of light) along a 'twisted rope' not made of dense matter at all. The 'rope' is made entirely of the charged particles themselves and the magnetic fields generated by those streams of current. Scientists call these ropes 'filaments'. When there are several of them seen at once, they are referred to as a filamentary structure. Sometimes they consist of substantial bundles of filaments, and sometimes of only two, which are literally a 'double helix'.<sup>1</sup>

Superconductivity is an extraordinary phenomenon, first observed in 1911, by which a current can pass through certain materials and experience zero resistance. Classical physics cannot explain how this works and the quantum mechanical explanation is still not complete. But in 1970, Laszlo Solymar and Donald Walsh, two particularly brilliant scientists, clarified the nature of superconductivity to a large degree by pointing out that superconductive filamentary currents consist of a central magnetic field surrounded by whirling layers of current vortices. They specifically stated: 'Thus, in a simplified manner, we may say that there is a normal region surrounded by a supercurrent vortex. There are lots of [layers of such] vortices ...' (Laszlo Solyar and Donald Walsh, quoted in Laszlo Solyar, Superconductive Tunnelling and Applications, Wiley-Interscience, New York, 1972.)

The illustration overleaf of a cross-section of a Birkeland Current shows such layers.

Birkeland Currents are far more efficient at conducting current than any dense matter conductor could ever possibly be, and they have very little current loss despite the fact that they can extend not only across our solar system but across our entire galaxy, and even beyond. Indeed, galaxies themselves seem to be linked by Birkeland Currents. There are many photographs of Birkeland Currents in space, and there are many on the internet and in books to which I shall refer in a moment.

The 'loops' that are seen extending upwards and outwards from the Sun's surface and from the solar corona (which is far above the surface) are also Birkeland Currents. They are sometimes called 'magnetic field lines' by astrophysicists, which is incorrect; they are actually the glowing traces of the charged currents themselves, and there are many photos of these currents taken from the International Space Station, which show a kind of eerie glowing green river running along beside the space station, and encircling the Earth.

The charged particles that reach the Earth from the Sun are mostly positively charged, made of protons and ions emitted by the Sun, and they stream along Birkeland Currents towards the north and south poles of our planet. They are literally space rivers of positive current streaming into our planet, and into all other planets in our solar system as well. What this means is that there are 'threads' connecting the Sun with all of the planets, which is thus in continuous direct communication with all the 'small fry' by means of these rivulets. Of course, the rivulets get all twisted up because of the revolutions of the planets, and sometimes the rivulets are shut off and then new ones start up again.

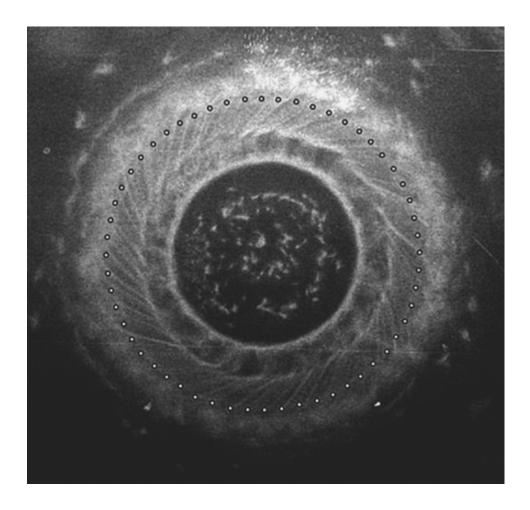

Figure 16. Cross-section of a dense plasma Birkeland Current captured on a photographic 'witness' plate in a plasma lab in 2007. The circle of dots is overlaid onto the image to indicate the 56 locations of the apparent spiral-shaped paths of matter. (Image supplied courtesy of Anthony Peratt, reproduced from Donald E. Scott's seminal paper, 'Birkeland Currents: A Force-Free Field-Aligned Model', in *Progress in Physics*, Vol. 11, Issue 2, April 2015, pp. 167–179.) The spiralling currents counter-flow, in other words, one ring flows left and the next flows right, etc., and the whole thing is spiralling forward (towards you, looking at the page) at great speed in a cylindrical 'skin' known as a 'double-layer sheath'.

Birkeland Currents beneath the surface of our own Sun are known to be 40,000 miles wide, as mentioned earlier. The ones linking stars are far larger, and ones linking galaxies in filaments to form 'the cosmic web' of the Universe are so gigantic that they are much wider than the diameter of any sun or star. Many have been observed and recorded by astronomers, including the Sloan Great Wall – a filament that is an amazing 1.37 billion light years long.

Birkeland Currents can also be microscopic. Our bodies are full of them. It is because of the nature of such infinitesimally small currents that we are

alive, as we will see in the final chapter.

The way in which the 'ropes twist' to form Birkeland Currents in a double-helix shape is really rather astounding. Does this remind you of anything? Yes, there is a distinct similarity between the structure of the DNA molecule and a Birkeland Current. Not only is this, in my opinion, no coincidence, but we shall see that since the 1970s there have been cell biologists insisting that charged currents flow along the DNA molecules inside our bodies, and that they are superconducting. Double helixes not only carry currents, they transmit information. All of this is getting us closer and closer to what I believe to be the nature and structure of a plasma body, and to the reasons for believing that intelligence can evolve in plasma.

But first we must return to look in more detail at the way Birkeland Currents function in space. We will see the current standard understanding of electricity and magnetism is still insufficiently developed for us to 'get our heads around it all'.

As one example of our failure to comprehend the great mysteries that surround us, I come to what we call magnetic lines of force, or magnetic field lines. These are constantly spoken of by scientists around the world, as if they really existed. But they do not exist.

Just in case you think I am being fanciful, here is what John P. Cullerne and Anton Machacek say in their physics textbook, *The Language of Physics: A Foundation for University Study*:

"... field lines are a fictitious pictorial representation of a field."

Field lines are used in the way that contour lines we draw on maps are used. The real landscape is not covered in contour lines. When we climb a hill, we do not say: 'Oh, I just stepped over a contour line.' Similarly, magnetic field lines are merely aids to visualization, and they are not real.

So where does this leave us? Didn't I say that Birkeland Currents 'follow magnetic field lines'? Well yes, I was using a figure of speech.

Now let us examine a bit more closely how a Birkeland Current is formed, and how it works. It all starts with a 'push' of currents of electrically charged particles emanating from a source.

The push forward of the current is facilitated by what we call an electric field.

At this point, I should pause to admit that although scientific talk on these matters is confident and well-established by custom, it is often hemmed in by ignorance. For example, we don't really know what fields are, but we talk about them nevertheless, until we find some other way of discussing them. I tend to believe that electric fields are spiral waves. So we have charged particles called electrons (assuming it is a negatively charged electric current, rather than a positively charged one consisting of protons and ions) spiralling along, pushed by something we call 'an electric field', though we don't know what that is, or what charge is either.

But to return to the questions of how a Birkeland Current is formed, we do know that electric fields are always perpendicular to magnetic fields. These currents flow as if along 'magnetic field lines', meaning they follow a direction laid out for them by a large pre-existing magnetic field.

As the currents move on their merry way, each creates a private magnetic field (known as an 'azimuthal' field) around itself in a circular fashion, which is thus at right angles to the electric field, but parallel to the larger magnetic field within which these tinier ones appear.

In Figure 17, we see a drawing published by Willard Bennett from his book *Fundamental Principles of Physics*, written jointly with his colleague Herman Heil, showing a section view of a normal copper wire carrying electricity. Remember that this picture is a slice across the wire and its surrounding field, and that the wire is coming straight at you. The black dot in the centre is the wire and all the circles round it are the 'lines of force'. Bennett describes the convention ('the usual agreement', as he calls it) whereby:

The lines in this figure are drawn nearer each other for positions close to the wire than for positions farther out, which is in accord with the usual agreement to represent field intensity by the number of lines per square centimetre in areas perpendicular to the lines of force.

And the drawing is, he says, to illustrate the fact that 'the magnetic lines of force are circular about the axis of the wire'. In other words, scientists have agreed a convention whereby the fictitious lines are drawn closer together to represent increased field strength, and further apart to represent declining or weaker field strength. There are no real lines, but there is assumed to be a

real field, just as on a contour map, there are real hills represented, but their contour lines are fictitious indicators of height and may be bunched closer together to indicate a steep incline.

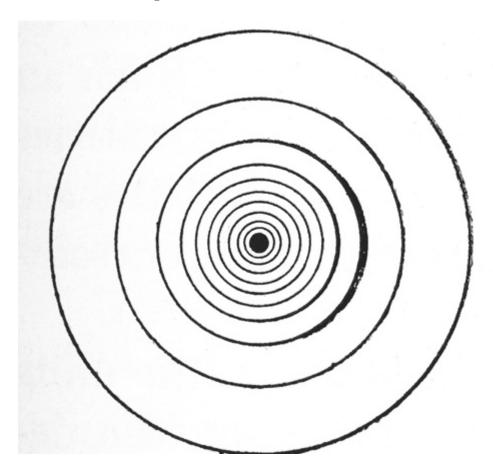

Figure 17. Willard Bennett's drawing. The fictitious 'lines of force' are drawn closer together the nearer they are to the wire (the black dot in the centre) to indicate increasing field strength. This is a section drawing, and the wire is coming straight at you in this picture.

With regard to electric currents, the self-generated mini-magnetic field of each current then constricts that current, as if it were choking it.

The first person to observe that magnetic fields at right angles to electric currents displaced the current and caused it to deviate in its course by a certain angle was Edwin Hall (1855–1938). He made this discovery in 1879, and it is named the Hall Effect, in his honour.<sup>3</sup>

What happens with Birkeland Currents surely is a kind of extension of this phenomenon of the Hall Effect causing a slight deflection of angle. But obviously we need to do a lot more work on this issue, and part of what needs to be done is to understand better the double-helix phenomenon of the Birkeland Current, as I shall now very briefly explain.

The magnetic currents applied at right angles to Birkeland Currents have the result that two currents running parallel to each other start wrapping themselves around each other in a kind of perpetual lovers' embrace. As we have seen, they twist up into a double helix and flow on like twisted ropes. Their two surrounding magnetic fields join and become stronger as a result. This constricts and compresses the plasma of the double helix further, and at occasional points nodes (special compressed points, like knots) are formed by this inward pressure, called 'Z-pinches'. (In fact, having been discovered and explained in 1933, and published in 1934, by Willard Harrison Bennett (1903–1987), certain types of the plasma pinches known as Z-pinches are now generally called 'Bennett Pinches').

Plasmoids (plasma blobs) form at these points and begin to spin, thus attracting surrounding particles and matter in space to themselves and forming clumps. These are essentially energy whirlpools or vortices. The current flowing through the Birkeland Currents then continues to supply energy, what is called 'becoming a maintenance current', supplying energy to the spinning plasmoid, which goes on expanding. It was suggested originally by Alfvén that by this means, gigantic Birkeland Currents streaming through space form stars, and continue to pump them full of electrons. The 'pinches' can also create atomic matter, X-rays, and vast quantities of neutrons (large particles with no charge, called neutrons because they are electrically neutral), in a portion of the pinch known as the 'sausage instability'.

At the Z-pinch points where matter gets sucked towards the streaming currents, a process called 'Marklund Convection' takes place. This is named after the Swedish plasma scientist Göran T. Marklund. The matter settles into layers, with the lighter elements wrapped around the inner part of the cylindrical current, and heavier elements forming progressive layers outwards. The different elements are thus separated spatially, and available for the formation of solid bodies in space in separate 'bundles', as it were.

A theory of 'the electric universe' has grown out of Alfvén's work; it states that our Sun has electrons streaming into its poles from galactic Birkeland Currents, and protons and positive ions then burst out of the Sun to form the solar wind.

According to this theory, our Sun is powered by streams of electric currents from a filamentary web of gigantic current streams linking all the stars in the galaxy.

On this view, Birkeland Currents supply huge currents of electric power and they are surging round the Universe in filaments. The filaments that fill the visible Universe are so obvious when seen through powerful telescopes, they have led to a widespread acceptance amongst astronomers of the idea that the Universe is a Cosmic Web.

The best practical reference source to turn to for a description of Birkeland Currents in astrophysics is Anthony Peratt's book *Physics of the Plasma Universe*, which appeared in a much-revised and updated second edition in 2015. Peratt was a pupil of Alfvén's, and he is the world's leading proponent of and expert on the 'electric universe' theory. As previously mentioned, he is a very high-profile scientist associated with American Government agencies. For several years he was Scientific Advisor to the US Department of Energy, and he has been the Acting Director, National Security, Nuclear Non-Proliferation Directorate. He has worked at Los Alamos on nuclear tests, and is internationally renowned for his plasma research, and Hannes Alfvén was his PhD supervisor.

Here is what Peratt has to say about the electric power filaments that I have just described:

The high conductivity of cosmic plasma permits electric currents to flow that constrict the plasma to filaments. These current-carrying filaments form transmission lines, which allow electric energy to be transported over large distances. Transmission lines consist of an assemblage of two or more conducting paths. Transmission lines on earth, used for communications and the transport of electric energy, employ conductors that are usually arranged parallel to a common axis [i.e., side by side]. This need not be the case in space and is often not the case in filamentary current-conducting plasma in pulsed-power generators. <sup>4</sup>

Figure 18 is an image showing the filamentary structure of the Universe above and the filamentary structure of a neural network below. We will see later in the book that a similar web exists in our bodies, more particularly in what we might call our 'plasma bodies'.

We will see that not only can we be confident that all dusty complex bodies such as the Kordylewski Clouds are filled like this with a web of filaments, we can also be confident that our bodies are too. The filaments meet and connect at intersection points, which scientists call *nodes*. In interstellar space these are stars. In intergalactic space they are galaxies. But at whatever scale, the pattern of a filamentary web keeps recurring.

Alfvén was, of course, the leading disciple of Kristian Birkeland. He and Peratt have carried forward Birkeland's ideas about Birkeland Currents. If Peratt's book is the ultimate 'bible' for this subject, Alfvén's book *Cosmic Plasma* (1981) is also fundamental. Alfvén and Peratt in turn have a disciple named Donald Scott, author of the book *The Electric Sky*. Scott is a retired Professor of Electrical Engineering living in America. My wife Olivia and I have been very pleased to get to know him and his wife Annis, and for me to have the privilege of speaking at the same conference with him on one occasion on the subject of the electric universe.

As for Birkeland, he was ridiculed in his lifetime for his theories about the aurora and was only proved correct in the 1960s when satellite data became available to us. Professor Alfvén was also ridiculed for supporting the theories of Birkeland, which he did from the 1930s onwards. But he too was finally vindicated, and was fortunate enough to live sufficiently long for this to happen in his lifetime, unlike poor Birkeland, who died prematurely. Alfvén Waves are named after him, and if something is named after you, things are certainly looking up.

Time and again in history, science seems only to progress via vicious ridicule, followed by vindication and reluctant, hypocritical acceptance by most of the people who have spent years insulting the innovative thinkers. Kristian Birkeland and those who have followed in promoting his idea of electric currents streaming through space, have defied orthodoxy and ridicule and have put forward a far more convincing explanation of how the Universe works. I certainly believe them to be correct.

The 99.9 per cent of the Universe that is plasma is not sitting there inert. It is fantastically active and dynamic.

And we shall shortly see that as plasma beings, we are part of that universal process.

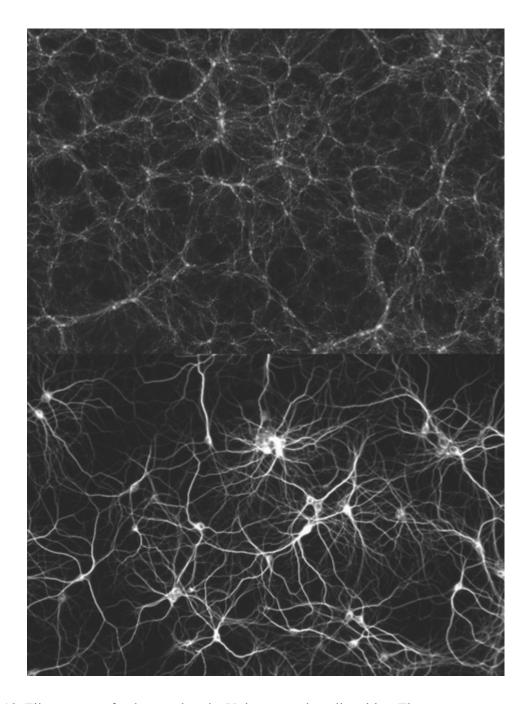

Figure 18. Filaments are fundamental to the Universe, and to all entities. They carry current. And they can carry information in the form of signals, they can transport energy, and so forth. In the Universe as a whole, they are everywhere. They constitute the major portion of the Universe's structure, which today is known as the Cosmic Web. Here we see two similar adjoining images. The top one shows the Cosmic Web of the Universe. The bottom one shows the neural network of the human brain. Both are constituted of masses of filaments separated by voids and joined at intersection points called nodes. The Cosmic Web is called that because of the web-like nature of the filaments, which many believe to be filamentary channels for the conduction of energy and currents across astronomical distances. Some scientists call them Birkeland Currents (named after the Norwegian scientist Kristian Birkeland), which contain current-carrying double-helixes spiralling forward and surrounded by protective sheaths. Such spiralling currents are sometimes conceived of

as 'super-conducting', meaning that they can travel without resistance at speeds approaching the speed of light. The upper image was posted on www.researchgate.net by astronomer Professor Oliver Hahn of the Lagrange Laboratory, Côte d'Azur Observatory, Nice, France, on December, 2014, as Figure 1 on page 2 of his paper 'Collisionless Dynamics and the Cosmic Web', from the *Proceedings* of the International Astronomical Union. (His paper with the image is available for free public download. Hahn does not himself discuss super-conducting currents or use the term Birkeland Currents.) The bottom image is credited to Matt Lee and was posted by eLife Science Digests (www.elifesciences.org/digests/37935) in an article entitled 'Traffic Signals That Wire the Brain', November 19, 2018. As with the Universe and its Cosmic Web, the Brain Web of a human being displays filamentary networks separated by voids and joined at nodes. Is the Universe a giant brain? Is the human brain a mini-Universe? In any case, these phenomena are examples of 'fractality' (a term arising from the study of fractal geometry), which means similar patterns and structures occurring at different scales, from the microscopic to the cosmic. Such reoccurrences of shapes are often referred to as the 'self-similarity' of forms which remain the same across different scales. These concepts arise from the pioneering genius Benoit Mandelbrot (1924–2010), discoverer of fractals. I was so fortunate to meet this heroic scientist on one occasion and attend one of his lectures. There are many videos of him on YouTube, which I enthusiastically recommend to all who wish to have their brains constructively stretched.

## The Cold Sun

We have all been told for our entire lives that the Sun is a raging furnace blasting out heat and light, which keep us alive here on Earth. The Sun is supposedly so hot that nothing one can imagine could survive for even a fraction of an instant without being melted and consumed and annihilated within its inferno. The Sun is inconceivably hot, inconceivably violent, inconceivably turbulent. It is like a great bully in the sky, roaring with rage and spewing out fire and rays.

But this is not true. And nobody could be more shocked than I was when I discovered this. It had made sense to me, having no specialist knowledge of all the other aspects of the matter, that the Sun must be the roaring inferno that was so widely claimed. And when I was told that it was powered at its core by the equivalent of an internal hydrogen bomb of fantastic and gigantic size, which generated all of its immense energy by the power of thermonuclear fusion and kept us all alive, I saw nothing to question in that. After all, where else could all that energy possibly be coming from? It must be true.

But then the conventional idea of the Sun began to fall apart for me, as I discovered some very strange facts in recent years. The ultimate discovery I made, which convinced me that 'nearly everybody is wrong about the Sun', was the revelation that the Sun is cold.

How can that be? Surely the Sun cannot be cold. You can see through telescopes that it is a turbulent mass of fire, spewing out blobs of fire into space, and it looks like a vast fiery creature gone mad.

But no. That is not accurate.

In fact, the 'surface' of the Sun, the technical name for which is the photosphere, is only about 5500 degrees Centigrade. (That is 5780 degrees

Kelvin, but I shall not use the Kelvin temperature scale in this book, because it is less familiar to readers.) Yes, that is hot for us humans. We would be burnt to a crisp in an instant if we were there. But it is not truly hot. It is less than four times as hot as the inside of a cement kiln here on Earth, in which limestone is roasted to make cement. And it is only about a third as hot as the electrons in a neon light bulb in an office.

Furthermore, it gets worse. If you go down into a sunspot, which is like a gigantic wobbling open mouth on the surface of the Sun leading down inside to unknown depths, our observational instruments have proved from a distance that the temperature drops to as low as 3900 degrees Centigrade.

What? You mean the Sun gets colder the further you go down into it instead of hotter?! How is this possible if it has got a big hydrogen bomb exploding continually at its centre? Well, the answer is that it does not have a big hydrogen bomb exploding at its centre.

The real heat of the Sun is found far above its surface, in what is called the corona. There the lowest temperature is two million degrees Centigrade, and it is believed that coronal temperatures can actually rise to several million degrees Centigrade. No one is sure of the upper limit, though four million degrees are often mentioned, and sometimes six million. But even the lowest temperature (two million degrees) of the corona is 350 times as hot as the surface of the Sun, despite the fact that it is so very far away.

Its lower limit is 1300 miles above the surface of the Sun. It extends from 1300 miles above the photosphere to the further reaches of the solar system. The Earth is actually within the Sun's corona, technically speaking. But the main part of the corona from the point of view of solar physics surrounds the Sun in a vast sphere of fire, which reaches several million degrees Centigrade, as already described.

If you were to travel towards the Sun (being miraculously immune to melting), you would pass through the genuine raging inferno of the corona, then you would travel sixty miles from a transition region until you reach a layer 1050 miles thick called the chromosphere, where the temperature would be a much lower 35,000 degrees, and finally after falling a further 250 miles, you would arrive at the photosphere, which I have already mentioned.

The photosphere is not solid, so you could not stand on it. But it looks like a surface from a distance, and so that is why it is called 'the surface of

the Sun'. And then you could make your way down inside the tube of a sunspot, with the temperature continuing to drop considerably, until you passed out of sight and after that we have no idea of what you might encounter. But the point to remember about this journey is that it keeps getting colder the closer you get to the Sun.

So clearly our conventional ideas about the Sun cannot possibly be correct.

The fact that the Sun is so cold and that the temperature drops as you approach the Sun, from several million degrees to only 5500 degrees, should be conclusive proof that the Sun cannot possibly have an explosion going on inside. Water does not flow uphill. Everyone knows that as you approach a hot stove, you do not get colder, you get warmer. But so deeply wedded are the majority of astrophysicists to their false theory of a thermonuclear explosion going on at the centre of the Sun, a theory originated by Sir Arthur Eddington (1882–1944), that they remain blind to the obvious.

Another point to keep in mind is why are those holes in the surface of the Sun known as sunspots not only colder than the surface, but also dark? Surely if the solar bomb theory were true, any holes in the photosphere would be blazing with light? But dark? So there we have it, the only sure indication of what lies beneath the solar surface is that it is cold and dark. This is far from the 15 million degrees of heat and explosion of light that the solar bomb theorists insist upon as being found at the core of the Sun, where their purported bomb is said to be going off.

Before returning to the question of how the Sun must really be powered, we need to learn a little bit about the 'solar wind'.

## The solar wind

As we learned in Chapter 8, the expulsion of solar material into supposedly 'empty' space was discovered in 1936 by the French astronomer Lucien Henri d'Azambuja. Until then, 'outer space' had been assumed to be totally empty, consisting of a perfect vacuum, with the exception of the solid orbiting bodies such as planets, moons, asteroids, etc., within the solar system and stars outside it. In other words, no medium was recognized.

However, we now understand that the solar wind consists of plasma together with admixtures of some atoms and a lot of dust, either negatively charged (by electrons) or positively charged (by protons and positive ions). Thus solar wind comes from the Sun and picks up dust on the way, although it has now been proved that plasma creates dust (as described earlier; see Chapter 3), so that some of the dust in the solar wind is thus plasma-originated.

In other words, the Sun is emitting in all directions a powerful 'wind' of plasma, which fills the entire solar system. It flows over the Earth constantly, blowing against and around the globe, being diverted in large part by the surrounding Van Allen Belts, or magnetosphere (see <u>Chapter 4</u>). But how long has this been going on? Has the Sun always been doing this, or is it something new? And could it ever end?

In 1977, Arthur J. Hundhausen, who was later to go on to become probably America's leading solar wind expert, published a summary paper entitled 'Plasma Flow from the Sun'.<sup>2</sup> By that time, there had already been fourteen years of satellite data, so that he was able to make reliable statements about the solar wind. He said that the evidence indicated that the solar wind had been blowing continuously for four billion years. That is a lot of wind, a long time span, and a very powerful Sun, with no end in sight!

In May of 1999, a very strange thing happened. For two days, the solar wind stopped completely. That certainly poses some problems for conventional ideas about the Sun. Did somebody turn off the central bomb? How can you turn off a thermonuclear explosion and then start it up again two days later?

The 'orthodox' view of the Sun at the moment is, as I say, that the thermonuclear explosion taking place at the core of the Sun powers everything. However, solar scientists admit that if the heat and energy from that explosion are to reach the surface of the Sun, by what they call convection, the process of the energy rising to the surface from the core could take 200,000 years. According to the Establishment theory, therefore, we are currently being warmed by radiation emanating from an explosion that took place 200,000 years ago. The results of today's core explosion will be felt on Earth in the year 202,017.

There are many bizarre solar anomalies that are ignored and glossed over at the moment. For instance, every 2 minutes and 40 seconds, the Sun shrinks in size and re-expands, or in other words rises and falls, by six miles. That's a long way to fall and a fast rise! There is no 'orthodox' explanation for this strange fact. Is the Sun breathing? If there were continual pressure from a thermonuclear explosion at the core of the Sun, how could that pressure 'breathe' every two minutes and 40 seconds? Are we to imagine a fusion process that has lungs?

The solar wind is mostly positive in its charge. Positively charged protons and ions spew out of the Sun continuously except for these short breaks. It seems that if it sheds too many positively charged protons and ions, it stops for a few minutes until it 'recharges', and then starts up again. As we saw in Chapter 8, huge streams of electrons pour into the polar regions of the Sun continuously from immensely long galactic Birkeland currents. This continual inflow of negatively charged electrons provides the pressure to expel the oppositely charged positive ions into space, which form the solar wind. This system of solar activity is described in 'the electric sun' theory. It provides a way for the Sun to operate for billions of years without the need for any central explosion at all.

Although some atoms are known to be created by the Sun, they are created under the intense temperatures of the corona, far above the main body. In other words, the temperatures needed to create the higher chemical elements are outside of the Sun's core body and take place in what is effectively its outer skin. This is like trees, the centres of whose trunks are essentially unproductive and simply inert wood, whereas the true life processes of the tree trunk take place in its bark.

Another major problem for the 'thermonuclear folks' who refuse to give up their hydrogen bomb in the centre of the Sun is what is known as 'the neutrino question'. It is admitted by everyone that there should be a very large number of the tiny nuclear particles known as neutrinos pouring out of the Sun as a result of any thermonuclear explosion. But the requisite number of neutrinos has never been detected. This embarrassing lack of neutrinos is often a source of public anguish to many in the 'astrophysical community'.

In the next chapter we shall look at more scientific discoveries, which show the Earth's relationship with the Sun to be very different from what we generally assume it to be.

## Invisible Earth

There is an Earth that is invisible to the human eye, and it surrounds the visible planet Earth. This other Earth is composed of plasma, and it is far larger than the 'solid core' on which we live. Which, then, is the real Earth? Or is the real Earth both together? The Invisible Earth was only discovered in 1958 thanks to satellite data by James Van Allen (1914–2006).

When James Van Allen's portrait appeared on the cover of America's *Time* magazine on 4 May 1959, with the news banner 'Space and the Radiation Belt' angled across the top, he became an instant American hero. He had discovered something called 'radiation belts' surrounding the Earth. Few people until then had any inkling that the Earth was protected from the solar wind by these shields, or 'belts', surrounding it. But then, prior to 1953, neither had any scientists. As for *Time*, the following year they did indeed name him America's 'Man of the Year' for 1960, thus increasing his fame, in case there was anybody left who had not yet heard of him, which was doubtful.

Inside the magazine, *Time* helpfully provided graphics that both recounted the sequence of discoveries and showed the now famous 'belts'. This sequence of graphics was headed 'Space Detective Story', to help everybody realize that it was only slowly and painfully discovered by intensive research stemming from rocket and satellite launches. The graphic sequence was divided into four boxes. Box One said: '1953 – Rockoons [small solid fuel sounding rockets fired in the atmosphere after becoming detached from a balloon, rather than fired from the ground] fired off Newfoundland detect first hint of radiation belt'. The picture showed a small red arrow pointing into space from Newfoundland in Canada. Box Two said: '1958 – Explorers I and III find lower portion of inner belt'. The

picture shows the inner belt in cross-section above the Earth, and informs us that it is 2000 miles thick. Box Three says: '1958 – Project Argus demonstrates charged particles follow magnetic lines of force'.

Project Argus involved exploding atomic bombs above the Earth, and the picture without the slightest embarrassment at this shows an exploding red star above the Earth labelled 'Atomic Explosions' and red lines showing the charged particles from those explosions circulating round the Earth, with the orbit of another satellite also indicated, which says, 'Explorer IV measures results'. And finally, Box Four says: 'Dec. 1958 – Pioneer III reaches 63,000 mi., establishes second radiation belt' and the picture shows this, labels it 'Outer Radiation Belt', indicates that it is 10,000 miles above the first belt, and there is a further arrow surrounded by dots that is called 'leakage of particles'.

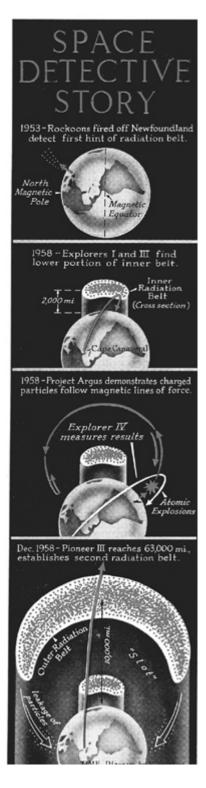

Figure 19. *Time* magazine's explanatory chart by V. Puglisi, of the discovery of the Van Allen Belts. The bottom picture shows how much bigger the Second ('Outer') Belt is than the First. A third higher Belt was discovered later. Note the shameless boasting about the 'Atomic Explosion' in the picture above the bottom one, complete with a helpful red explosion. How incredibly naïve, or should I say stupid, the military authorities were, and how idiotic the editors of *Time* must have been, to

print this without any indication that they had turned their brains on and realized that maybe this was possibly not such a good idea.

Thus did the public get their necessary basic science lesson and see what it was that Van Allen had discovered. There was a lengthy article to explain it all much further, and to describe the man himself. The magazine informed everyone:

In the race into space, the Russians can claim bigger satellites and more powerful rockets. If the U.S. can retort that it has a big lead in scientific achievement, the man most responsible is James Van Allen, whose instruments, designed and largely constructed in his basement laboratory, brought back from space discoveries the Russians never made.

But Van Allen never expected to find himself, at forty-four, a key figure in the Cold War's competition for prestige. He is and always had been, by inclination and intent, a 'pure' scientist. His real interest is in cosmic rays. He started being curious about cosmic rays back in the prewar days when they were considered as wildly abstruse and impractical as a study of the mating habits of sea horses, or the inner structure of a grasshopper's brain. But today he can tip back his head and look at the sky. Beyond its outermost blue are the world-encompassing belts of fierce radiation that bear his name. No human name has ever been given to a more majestic feature of the planet Earth.

Readers were also reassured that Van Allen was 'about as American as a man can be'. He came from Iowa and his mother was raised on an Iowa farm, doubtless making apple pie from an early age. As for his Dutch surname, everyone was reassured that those Dutchmen on his father's side 'came to the US soon after the Revolution' and hence had been thoroughly imbued for two and a half centuries with the necessary American credentials and patriotism.

All of this publicity was carefully crafted as part of the Cold War PR battle between America and the Soviet Union. But it had a value as regards popular education in science, because you could only with difficulty find anyone in America after the spring of 1959 who had not heard that there were some kind of strange radiation belts surrounding the Earth, and that they were called Van Allen Belts because the American hero Van Allen had discovered them, from his basement, no less, and those irritating Russians had their noses out of joint as a result. 'They' may have had their Sputnik and Gagarin, but 'we' had Van Allen.

At least all this publicity taught the public something about what surrounds the Earth beyond the breathable atmosphere. Perhaps if there had been no Cold War and Van Allen had not been publicized so widely, the public would have remained ignorant of the Van Allen Belts for many decades to come. Sometimes public education in science comes in strange ways!

In 1956, while Van Allen was still a lowly and unknown scientist ostensibly working quietly at the University of Iowa, he published a book entitled *Scientific Uses of Earth Satellites*. In fact, Van Allen was probably already working for the Electronics Program Office of the US Office of Naval Research, albeit usually physically present in Iowa. The Office of Naval Research is essentially one of the many American intelligence agencies, one that specializes in scientific research, and we will later come across it as the employer of Freeman Cope. The Army and the Air Force have their own equivalents, but the Naval one tends to have the highest reputation for high quality scientific work. All three of them could either operate independently or operate as 'covers' for the CIA.

It is very common for talented scientists spread across the universities of America to have their salaries paid ultimately by government intelligence agencies, sometimes not even the intelligence agencies whom they think are paying them, but instead by one hiding behind another, and the universities like this because they get high profile professors for free. The downside is that the Government 'owns' those men and women, who have to sign onerous contracts that give the agencies power to withhold publication of much of their most important work, and even to slap secrecy restrictions on what the scientists can say about it to friends and colleagues.

Since 1947, the US Government has had the power to declare any scientific work taking place in America 'secret' and restrict its publication on grounds of national security, and these restrictions do not have to be explained or justified. Everyone in the security world knows that there is a great deal of unnecessary 'overclassifying' going on, with material declared secret without any rational justification. But there is very little oversight for this process.

In other words, a very substantial proportion of America's ostensibly disparate scientific community really works secretly for the Government, or as conspiracy theorists like to say, 'for the CIA', using 'the CIA' to stand for the plethora of intelligence agencies including the Office of Naval Research (now apparently absorbed into DARPA or Defense Advanced Research Projects Agency), which are all lumped together for the sake of ordinary conversation as 'the CIA'. It is publicly admitted that there are at least

seventeen different intelligence agencies in America. Many are genuinely separate agencies, which exchange information with each other from time to time, and are theoretically coordinated today by a central body, the competence or incompetence of which is of course secret, even from the politicians, so who knows whether it all works seamlessly or not, and who will ever know.

In the Appendix 3, Bibliography for Van Allen (here), it may be seen that under the dates of 1979 and 1982 are listed articles by Van Allen that are stamped 'released for publication' by the US Department of Defense. In other words, just about everything Van Allen wrote could only be made public with the specific written permission of the Government. So we will never know how many of his studies remain secret, and there are bound to be many of them. In evaluating the work of Van Allen, we must always keep this in mind, that we know only part of the story and will never know the whole of it.

Some aspects of Van Allen's work are barely documented in archives open to the public at all. For instance, the fact that he was intensely active in trying to find out how to make better semiconductors is only revealed by the fact that his contribution to a 1961 conference on the ultra-purification of semiconductor materials was included in the Proceedings of the conference published by Macmillan as a scientific text in 1962. The reason why 'ultra-purification' is so important for semiconductors is that the purer the chips are (at that stage they would have been made of either silicon or germanium), the better the electrons flow in them, and the more efficient they are.

I have been in a chip factory and seen that the fanatical obsessions with purity and cleanliness are a commercial necessity. Everything takes place in 'clean rooms' into which one cannot enter, though you can see into them through windows from a corridor. The slightest speck of dust is enough to frighten everyone in the building. But people do not tend to know that Van Allen was involved in all of this. Instead, Van Allen will forever only be associated with scientific space exploration.

Since 1953, seven years before the article in *Time*, rocket launches had been detecting some anomalous radiation phenomena in the high atmosphere. But it was only in 1958 that satellites were launched, which instead of shooting up into the atmosphere and then quickly falling down

again, as rockets did, could continuously monitor the high regions for radiation. The very first such satellite, which was later publicly known as Explorer I, had initially been called simply Satellite  $1958\alpha$ , identified by the year of launch and the Greek letter *alpha*, which being the first letter in the Greek alphabet signified that it was the first satellite launched that year. This satellite detected unmistakable signs that there was a belt of radiation surrounding the Earth. The second satellite, later known as Explorer II, did not search for such information. The third satellite,  $1958\gamma$ , tagged with the Greek letter *gamma*, which is the third Greek letter, came to be known as Explorer III and it confirmed what Explorer I had found.

In his book of 1956 and in a five-page article of 1957, Van Allen had published accounts of what the earlier rockets had detected, which he still referred to as 'auroral radiation'. By that he meant that he thought he had detected the source of the radiation that streams down and forms the Aurora Borealis, and perhaps also the polar ring current made mostly of protons and positively charged ions that circulates in the Earth's magnetosphere far above the atmosphere.

After the Explorer satellite findings, still referring to them as Satellites 1958 Alpha and Gamma, Van Allen and his colleagues on his team (George Ludwig, Ernie Ray, and Carl McIlwain) published a series of three articles in 1958 reporting on the amazing discoveries of a radiation belt around the Earth. These findings entirely superseded the accounts published only the year before from rocket findings. After that, Van Allen switched to the *Journal of Geophysical Research* as the medium for announcing his further findings, and published numerous articles in that periodical of the American Geophysical Union in Washington. At the same time, he became a member of the Board of Editors of that journal, and an Associate Editor. Due to his official ties with the journal, it was clear that he owed that publication the loyalty of allowing it to be the chosen vehicle for reporting his findings.

The next thing that happened in 1958 was Project Argus (but to consult it on Wikipedia you must type in instead 'Operation Argus', since 'Project Argus' is a name today better known as one applied to a police operation). This involved sending three atomic bombs up into the high atmosphere and exploding them, as already mentioned. The first bomb was of 10 megatons and was detonated on 1 August 1958. This bizarre project is worthy of extended discussion, which unfortunately in this book would be too great a

digression. The bombs sent charged particles hurtling along magnetic field lines and the results were monitored by the satellite Explorer IV.

This helped scientists understand the radiation belt better. Whether it was good for the Earth and its inhabitants seems not to have been considered! The motto of the people launching the rockets and satellites seems to have been a heedless 'when you gotta know, you gotta know', and the hell with what the consequences might be of blowing up all those atomic bombs above people's heads. The damage done to the atmosphere by this crazy and irresponsible project (one of the bombs was truly gigantic and incredibly dangerous), forms part of the sad history of mankind's progressive destruction of the ionosphere by military organizations, which I believe is the true cause of climate change, much more important than any carbon dioxide emissions.

Van Allen's first article to appear in his newly affiliated journal was published in March of 1959 and was entitled 'Radiation Observations with Satellite 1958ɛ', the Greek letter *epsilon* signifying that year's fifth satellite. It was written jointly with his colleagues Carl Edwin McIlwain and George Ludwig. (McIlwain was a young researcher who had made one of the key observations.) Here are some of the remarks from that article that are of great historical importance and of deep interest:

The earlier discovery of the great radiation belt around the earth with Satellites  $1958\alpha$  and  $1958\gamma$  has been confirmed and greatly extended with an apparatus of much greater dynamic range and discrimination. It appears likely that many important geophysical phenomena are intimately related to the reservoir of charged particles found to be trapped in the outer reaches of the earth's magnetic field ... The existence of a high intensity of corpuscular radiation [radiation composed of particles] in the vicinity of the earth was discovered by apparatus carried by Satellite  $1958\alpha$ , launched at 03:48 on February 1, 1958 ...

The data from 1958α and 1958γ showed that: (a) The intensity of radiation up to some 700 km was in good accord with that to be expected for cosmic rays only ... (b) Above some 1000 km (this transition altitude being longitude and latitude dependent) the intensity of radiation increased very rapidly with increasing altitude, in a way totally inconsistent with cosmic ray [rays coming from space] expectations ... It was proposed in our May 1, 1958, report ... that the radiation was corpuscular in nature, was presumably trapped in ... lunes [arcs of three-dimensional space with thickness and shaped like crescents], about the earth, and was likely related to that responsible for aurorae.

On the basis of these tentative beliefs it was thought likely that the observed trapped radiation had originally come from the Sun in the form of ionized gas, which may or may not have been subject to acceleration in the outer reaches of the Earth's magnetic field ... The existence of such radiation had been presaged by our earlier rocket observations ... We are not at this date prepared to report a range spectrum of the radiation, nor are we able to offer a definitive

appraisal of the important matter of whether the more penetrating component consists of protons, of electrons, or of X rays ...

On the basis of the evidence presented above, we regard it as established that the great radiation belt around the earth consists of charged particles, temporarily trapped in the earth's magnetic field ... The radiation belt may well be the seat of a distributed 'ring' current encircling the earth, and the perturbations of the belt due to arrival of solar plasma may be directly responsible for solar storms. No detailed study of this possibility has yet been made.

What Van Allen had discovered was confirmation of the hypothesis put forward by Kristian Birkeland. Furthermore, without apparently fully realizing the significance of what he was saying, Van Allen said that maybe there was a 'ring current' around the Earth. This article therefore can be considered as the first appearance in print of physical confirmation of Birkeland Currents in space. But Van Allen and his colleagues were still struggling with the concept of plasma in space. They persisted in referring to what came from the Sun as a 'gas', albeit an ionized gas, which they hesitantly called a 'solar plasma'. But at this stage, no one yet understood the true nature of what we today refer to in common parlance as 'the solar wind', the massive streaming of plasma from the Sun outwards into the entire solar system, and bathing the Earth.

In December 1958, the satellite Pioneer III discovered the second radiation belt, high above the first and much larger. It was during this same year of 1958 that Eugene Newman Parker proposed the existence of what we now call 'the solar wind'.

During 1958, Van Allen approached the scientist Tommy Gold for advice on how to understand and interpret the satellite findings. In his article just quoted, Van Allen says: 'We are grateful to Professor T. Gold for an opportunity to discuss a number of matters of general physical interpretation ...' As I mentioned earlier, Tommy Gold (1920–2004) and I were good friends towards the end of his life. It was in 1959 that Tommy coined the term 'magnetosphere' to describe the plasma regions above the Earth, including the newly discovered Van Allen belts. I believe it was Tommy who edged Van Allen and his colleagues away from the idea that what was coming from the Sun was simply ionized gas, and tried to get them to think of it as plasma, which as we now know is correct. He could see that the plasma consisted not primarily of atoms of gas, but instead of charged particles. Tommy thus did a lot to advance our understanding at this stage.<sup>1</sup>

In 2013, a temporary third Van Allen Belt was discovered by NASA, but it was subsequently destroyed by a shock wave from the Sun. Or so the story goes, though it may simply be a cover story to explain its destruction by human interference. The second and outer Van Allen Belt is now known to consist largely of electrons, whereas the inner and smaller one consists of a mixture of protons and electrons. It was only in 2014 that it was discovered that the inner edge of the outer Van Allen Belt is very sharp and highly defined, and resembles a protective barrier. Scientists are still trying to understand that discovery.

This finding is, however, precisely what one would expect, because plasma regions whether large or small are routinely surrounded by closely fitting plasma sheaths, which are rather thin, and their edges do tend to be very sharp and highly defined, as we now know is the outer Van Allen Belt. In other words, what continues to be discovered about the Van Allen Belts provides increasing evidence that they are standard plasma belts of the classic type. Our planet is thus the solid core of a vast plasma entity that surrounds it. We need to accept that the Van Allen Belts and the atmosphere are the Earth just as much as the solid core.

Our planet is more than solely a round ball in space. If we remember the fairy tale of the princess and the pea, we might compare the planet on whose surface we live to the pea under the mattress. All we have to do is bend the mattress into a sphere, suspend the pea in the middle, and presto, we have the Whole Earth. The fact that the mattress is invisible to our retinas, and we can see only the pea, is neither here nor there.

# Radiant Matter, Plasma and Plasmoids

For the last few chapters we have been considering the existence and flows of plasma in space and how these came to be recognized and understood. Now we turn from the cosmically large scale to the absolutely minuscule, and to the story of how plasma came to be discovered and explored within the laboratory.

Winston Harper Bostick is one of the great heroes of this history. He followed in the footsteps of Langmuir and Spitzer. He was a contemporary of Alfvén, and their work intertwined.

Bostick's great individual contribution was his discovery of plasmoids. Plasma is all around us, as we have seen, making up over 99 per cent of the Universe. A plasma is a distinct entity that has emerged from the great plasma soup, and a plasmoid is a type of plasma, which as we are about to see is often spherical or blob shaped, or sometimes shaped like a doughnut – and it also has strange properties.

It is worthwhile recounting what happened in some detail, because what was discovered and the manner in which it was discovered reveal so much of importance. In the mid-1950s, the 39-year-old Bostick was working as a scientist in the brand-new Radiation Laboratory of the University of California at Livermore. It is today called the Lawrence Livermore National Laboratory.

The lab had been created in 1952 by Robert Oppenheimer's best friend E.O. (Ernest Orlando) Lawrence (1901–1958), who had won the Nobel Prize for Physics in 1939, and Edward Teller (1908–2003), who is often called 'the father of the hydrogen bomb'. It was created to supplement the US Government's nuclear warfare research at Los Alamos. The Livermore Lab continues to be entirely controlled by the US defence establishment and

proudly announces on its website today that for more than half a century it 'has applied cutting-edge science and technology to enhance national security'.

Bostick was asked to investigate the firing of plasma into magnetic fields, in order to see how the magnetic fields might become deformed, and to study the interactions between plasma and magnetism. In particular, he was to look for 'the manner in which magnetic-field lines can be dragged and twisted' (as he said in an article of 1938). This had many defence implications, especially relating to the hydrogen bomb, as well as being relevant to the potential control of nuclear fusion for purposes of producing energy, as nuclear fusion can theoretically be confined by magnetic fields. (Any solid material such as steel used in an attempt to confine super-hot plasma would simply melt.)

Bostick had assumed that he would be firing bursts of plasma at a magnetic field and that they would essentially be 'blobs of plasma', and that it was the magnetic fields and not the blobs that would be of interest. He was not at all prepared for what actually happened. If he had discovered something of lesser importance, it would probably have been swallowed up in the gigantic secrecy machine that eats most scientific research done for defence purposes in America. However, what Bostick found was of such earth-shaking importance that he had to be cleared to publish accounts of part of what he had discovered – because it was so game-changing in physics that worldwide debate was clearly going to be necessary to try to figure out what it all meant.

Funded by the US Atomic Energy Commission, Bostick had invented what is called a 'plasma gun', which he refers to more conservatively as 'a button source' (because the tip of the 'gun' was like a button), and he began using it to fire plasma into a magnetic field in his lab. And this was when the surprise discovery was made.

Eleven months later, Bostick's lengthy report, accompanied by many photographs, was published in *Physical Review*, under the title 'Experimental Study of Ionized Matter Projected across a Magnetic Field'. In this article he announced:

... the plasma is emitted not as an amorphous blob, but in the form of a torus [the geometrical term for a doughnut shape] ... We shall take the liberty of calling this toroidal structure a

plasmoid, a word which means plasma-magnetic entity.

In a footnote at this point, Bostick was careful to give the credit to the Princeton physicist David Pines for coming up with the term 'plasmoid'. Bostick had originally thought of using the term 'plasmon', also a term coined earlier by Pines. But Pines pointed out to Bostick that 'plasmon' would really be inappropriate for technical reasons, and so Bostick happily adopted Pines's suggestion of the word 'plasmoid' instead.

I contacted David Pines and asked him the details of the naming of plasmoids, and this is what he said in an email to me in December 2015:

You are correct, I did suggest the name to Winston, as plasmon, a term I had earlier coined, was in the process of becoming widely used to describe a quantized plasma oscillation, just as phonon describes a quantized sound wave. And now we have plasmonics and nano-plasmonics as a major sub-field of nano-electronics.

In case anyone is wondering what 'a quantized wave' means, it refers to part of a wave forming something resembling a particle, in other words the ripple (technically called an 'oscillation') becomes a thing. The best description of this, together with the analysis of the equations applying to it, and the formation of what he called 'singular regions' by a wave, was done by Louis de Broglie in the 1950s, and I have given a lengthy exposition of this in my technical paper 'Is Particle Mass a Function of Degrees of Freedom?' in 2016, a paper that may be downloaded from my entry on <a href="https://www.researchgate.net.2">www.researchgate.net.2</a>

So it was that the word plasmoid was coined, which was to be one of the key words of the physics of plasma to come. This 1956 paper by Bostick is thus of immense historical significance. And I am happy to add further clarity here about David Pines's crucial contribution, for the historical record.

In Figure 20, I reproduce the first published drawing of a plasmoid, which appeared in Bostick's article of 1956. The three-stage drawing shows the plasma emerging from the plasma gun at left in the form of a ring, and then breaking free and becoming a closed ring, or torus. By this point the plasmoid was about 5 cm in diameter. Numerous photos were also published with the paper, showing many other strange and unexpected phenomena.

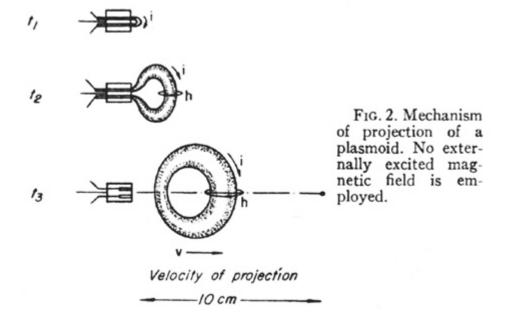

Figure 20. How to make an electric doughnut: the 'plasma gun' is at left, and from it emerges in three stages (shown as t1, t2, and t3, meaning 'time one, time two, and time three') a plasmoid in the shape of a doughnut, known in geometry as a torus. This is Bostick's own diagram from his famous 1956 paper, and depicts the first plasmoid ever created artificially in a laboratory.

#### Bostick's discoveries were truly revolutionary. As he says in the paper:

In spite of the fact that there has recently been considerable theoretical interest in the interactions of plasmas and magnetic fields, there had been no theoretical predictions concerning the existence of plasmoids ...

In other words, no one had ever imagined that such things as plasmoids existed or could exist.

The discovery that bursts of plasma were not merely shapeless blobs but were tori (the plural of torus, i.e., doughnut-shapes) was bizarre enough. But things got much, much stranger than that. In his article and others that followed, Bostick described these features. In this first plasmoid paper, he discussed the interactions of plasmoids with each other:

Rather interesting and unexpected effects are produced when two plasmoids are projected at one another across a magnetic field ... For example, the photograph ... shows an interaction that looks (at first sight) like an elastic collision of two billiard balls ... More striking effects can be obtained when two plasmoids are fired at each other when the pressure in the vacuum chamber is raised ... These effects become even more spectacular when four sources, instead of two, are employed ...

When four plasmoids were fired at each other, they spun into dramatic spiral shapes, of which Bostick published photographs. They seemed to him to be behaving as living entities. 'In other words,' he wrote, 'we appear to be dealing with bodies which have strong powers of self-organization and preservation.' He also described the plasmoids as being made of a 'self-organizing putty'.

Bostick became so excited by this that he also reverted to an earlier concern with galaxy formation, and wrote: 'It is possible to apply the knowledge gained concerning the nature of plasmoids to a hypothesized process of galaxy formation ...'

What Bostick is getting at here is that the behaviour of charged plasma and plasmoids may be similar at all scales of size, from these tiny plasmoids in his laboratory to the scale of entire galaxies in space.

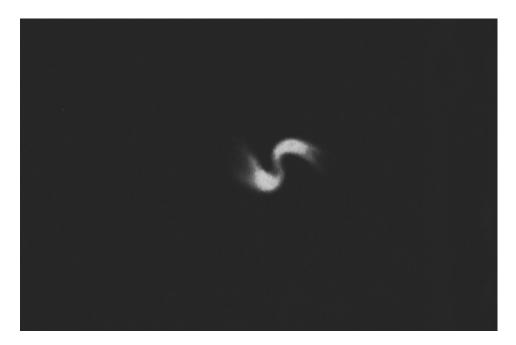

Figure 21. Bostick's photo, taken as a two-microsecond 'snapshot', showing what happened when he fired two plasmoids at each other. To his astonishment, they combined to form a 'barred spiral' shape resembling the well-known barred-spiral galaxies in space. As he wrote: 'Occasionally two plasmoids crashing head on break into fragments, but even these fragments seem to behave as entities. In other words, we appear to be dealing with bodies which have strong powers of self-organization and preservation.'

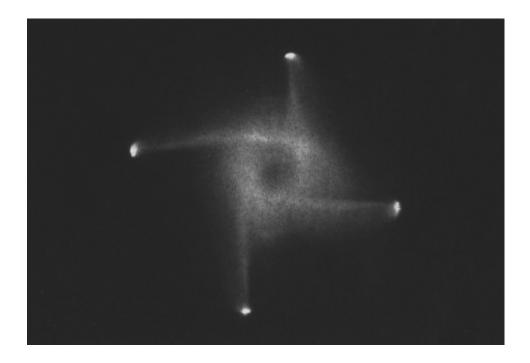

Figure 22. Bostick's time-exposure photo of what happened when he fired four plasmoids at each other, by aiming all of them at a common central point. He did this in a thin gas within a magnetic field, which is at right angles to this page. As soon as the plasmoids were fired, they ionized the gas so that electric current started flowing. The effect was this astonishing phenomenon, of a twisting and whirling ring with spiral arms.

As he says: 'The formation looks strikingly like a photograph of a spiral galaxy ... We can look upon the combination of plasma and a magnetic field as a kind of self-shaping putty. Perhaps study of the forms assumed by this putty may help us understand configurations such as the stars and galaxies. It may also throw light, at the other end of the scale, on the construction of fundamental particles such as the electron, the proton, mesons and neutrinos. They, too, may be made of self-organizing putty: a putty composed of the electromagnetic field and its own gravitational forces, which, working together, create the bodies we know as particles.'

He then gave cosmological details about that, which we need not go into, except to point out that he was clearly developing the idea that the tiny plasmoids in his lab were in his opinion models of what took place in interstellar space, with plasmoids essentially spanning reaches of space that would eventually contain many millions of stars.

However, this was mostly bad news for Bostick's bosses. They wanted bombs and power plants, not galaxies. Bostick was perhaps beginning to look too much like an idealist to make the generals comfortable. They had been hoping for something quite different, an easy way to handle plasma in a magnetic environment. They did not want plasma to start misbehaving and running amok in Bostick's lab like that and forming things that were bouncing off each other and appearing to be solid. But of course they had to

find out more, so Bostick continued his investigations. And 'worse' was to come.

The pace of work and of publication now sped up. By 1 January 1957, a further article appeared in *Physical Review*.<sup>3</sup> This time Bostick was joined by two other authors, E.G. Harris and R.B. Theus, both military scientists brought in from the Naval Research Laboratory in Washington. It seems that Bostick was to work from now on with men who had military requirements and interests foremost in their minds and would perhaps keep an eye on him. Harris was a specialist in hot plasma physics. Theus was born in 1921 in Tennessee, joined the Army in 1943 as a private, and by 1956 was a nuclear scientist specializing in radiation and particle beams, who would later study the effects of radiation exposure on organisms.

The new paper was called 'Experimental Investigations of the Motion of Plasma Projected from a Button Source across Magnetic Fields'. It reported new studies showing that the speeds of plasmoids could be increased by aligning the magnetic field in a particular way.

However, there were even more unusual findings:

The great variety of curious and unexpected phenomena observed seem to indicate that the plasma does not move as an amorphous 'blob' but must possess some sort of structure that is stable for the length of time involved ... We shall refer to this structure as a plasmoid. The purpose of the series of experiments reported here is to gain some insight into the structure of these plasmoids, the way in which they are formed, and the mechanism by which they move across magnetic fields.

One of the new experiments was to shoot a plasmoid at a 0.65 cm wide hole in a copper plate to see if it would go through, which it did. This was done several times and occurred in both the presence and the absence of a magnetic field. But when a magnetic field was applied, after going through the hole, the plasma stretched out at right angles to its course. They then placed a wire screen with a 2 mm mesh in front, and the plasmoid went through that even though it was far larger than 2 mm.

So then they thought, as plasmoids bounce off one another, perhaps we can bounce one off a copper plate with no hole. What happened next was really disturbing. The plasmoid passed through the copper plate as if it were not there, a phenomenon we have already noted in relation to lightning balls – and 'fermions' on the quantum scale – and which is also similar to the behaviour of angels and other spiritual beings as reported in religious

traditions. Furthermore, the plasmoid did not merely go through the metal sheet head on, it even went through the entire length of the sheet when the sheet was placed flat in its path in a failed attempt to bisect the plasmoid.

Now the military people really had something to spook them. They could produce plasmoids that could pass through considerable thicknesses of metal. What could this possibly mean for potential future weapons? For the vulnerabilities of the walls of tanks? For the sides of aircraft? For the White House itself, which did not even have copper walls?

Little interest is taken these days in Bostick's work, because only a minority of scientists show an active interest in recording the history of discoveries in their fields. The ones who do take the trouble often do a wonderful job, however. If only there were more of them! But as far as Bostick's work is concerned, I have not come across any attempt to chart his efforts since the American Physical Society issued a reprint of some of his key articles in 1963, in the form of a pamphlet.<sup>4</sup>

I have managed to collect original copies of everything that was made public by Bostick at that time. I have found over many decades of studying the frontiers of science that one learns the most about a new subject by very carefully scrutinizing the earliest publications, where unguarded remarks are often made and speculative hints are dropped by the enthusiastic discoverers and their colleagues. This is especially the case with work done for military authorities. But the censors and secrecy guardians at first tend not to understand the full significance of new discoveries, so they do not always know which aspects of the new things they should be censoring; it takes them a year or two to figure it out.

So often the only time one can get some deeper insight into the new discoveries is from the initial reports. Then the steel curtain is drawn down upon the subject and no one dares talk or publish at all without written approval and very strict controls. I have known many fascinating scientific subjects to vanish entirely from public view because of paranoid censorship. Military and 'security' people tend to have no concern at all for the public's understanding of science; they are only interested in weapons and what they call 'public safety'. They make decisions, often holding science back by decades by suppressing knowledge of crucial developments.

Although the next article by Bostick to appear in print was his article 'Plasmoids' in the *Scientific American* for October 1957,<sup>5</sup> the next development in terms of the chronology of discovery was a paper of his which, although not published until 1958, had been delivered to an international conference in August of 1956 in Stockholm.<sup>6</sup> This was a live talk, the text of which was then published, with many photographs plus the text of the conference discussion that followed the delivery of the paper, in the Proceedings of that conference. Since it often takes a year or two to get such mammoth volumes containing contributions from scientists all over the world edited and printed, that was why it did not appear until 1958. This is the one paper by Bostick usually mentioned in footnotes by contemporary scientists, who have not bothered to look up his other publications. The Stockholm conference was organized and chaired by that giant figure in plasma science, Hannes Alfvén, whom we already know from Chapter 8.

Even though it was really a 1956 paper, I shall call it Bostick's 1958 paper, after its year of publication, because that is what everybody calls it. When he delivered it, Bostick was still at the Livermore Lab, but by the time of publication in 1958, he had moved to a new institution. A footnote was added describing him as 'Now at Stevens Institute of Technology, Hoboken, N.J., U.S.A.' The Stevens Institute is hardly a household name, but it is an extremely important centre of scientific and technological research on the East Coast of America, not far from New York City.

Bostick became Professor of Physics and Head of the Physics
Department. Perhaps he was glad to get away from people preoccupied with
military matters and be free to do some normal science, without being asked
all the time what kind of weapon it would be good for. And who knows,
perhaps he was glad to escape certain colleagues as well. He did remain a
consultant to Livermore and in 1973 even spent a summer there on a special
project with Oved Zucker. But his best colleagues appear to have been the
ones at Stevens, his closest being Vito Nardi, with whom he worked for
decades. Nardi's name will come up again later.

In his 1958 paper, Bostick extended his insights into plasmoids by saying something truly remarkable: 'It is entirely possible that ions and electrons ejected from the Sun come to Earth in the form of a plasmoid.'

This is an astonishing suggestion, which was later adopted by Hannes Alfvén, who also believed that huge plasmoids came in the solar wind all the way to the Earth from the Sun. Indeed, in his book *Cosmic Plasma* (1981) Alfvén even spoke of plasmoids being fired from the Sun as if from a plasma gun, thus carrying the analogy with Bostick's work even further.

What is important for our argument here is that giant plasmoids from the Sun, given the complex behaviour that led Bostick to think of them as living entities, could easily be so intricate and complex in their structure that, in line with the discovery of the Kordylewski Clouds, they could even be intelligent or conscious entities. The implications of that would truly be limitless. Just imagine, for instance, that every plasmoid belched forth by the Sun and reaching the Earth or one of the Kordylewski Clouds could be in effect a program (in the sense of a computer program) and in that sense a communication of intelligence.

In that scenario, the Sun could be controlling the Earth's atmospheric phenomena directly when it wishes. Such plasmoids could also in principle contain information that receptive people could perceive indirectly as 'inspiration'. The Sun could 'talk to' the Kordylewski Clouds, the planets, our higher atmosphere, and anyone else who is listening. SETI people should really look for coded information concealed in plasma bursts coming from the Sun. But before we can explain that, we need to know some more about the fundamentals of plasmoids, and their habit of emitting signals.

Bostick reported that he had detected from his laboratory plasmoids 'signals which are believed to be associated with the magnetic fields trapped by the plasmoid'. He says 'the structure of these signals is too complex for analysis'. If that is the case for tiny plasmoids in a lab, how complex might we expect them to be in a gigantic solar plasmoid striking the Earth's magnetosphere and interacting with it? Bostick elaborates further on the solar plasmoids:

It is quite possible that ionized material ejected from the surface of the Sun proceeds and escapes across the magnetic field of the Sun in the same manner that laboratory-produced plasmoids cross a magnetic field.

Bostick then goes on to talk about how he is playing with multiple plasmoids in his lab:

... several of these plasmoids can be made to spiral in consort to produce a ring of plasma ... not only is the torus produced automatically, but also ... it is stationary ...

Experiments showed that plasmoids could turn into standing waves, so like ball plasmas behaving like the quantum phenomena already alluded to known as solitons.

There are many books and papers describing solitons, but to go into them in any detail would take us too far afield. The important point to note here is that we have yet another example for the development of one of the weird phenomena observed in the quantum realm occurring in the 'human' or macro realm. They can also exist within the human body, a subject discussed in numerous publications by Alexander Sergeevich Davydov (1912–1993), who was Director of the Institute for Theoretical Physics of the Ukrainian Academy of Sciences. Two of his key books are *Solitons in Molecular Systems* (1985) and *Solitons in Bioenergetics* (1986).

Bostick's descriptions of his plasmoids became increasingly eerie:

One of the simplest ... results which must be understood is the 'barred spiral', which is produced by firing two sources at one time across a magnetic field ... the two plasmoids seem to seek each other out unerringly.

Not only do we now have hunting plasmoids, we even have mating ones:

... the leading edges of the plasmoids seem to seek each other out and latch on to one another ... After the union of the two plasmoids has been accomplished ... the angular momentum will wind them up into a spiral ... The resultant plasma and magnetic configuration then seems to be stable ... It is rather astonishing that such a bizarre configuration of plasma and magnetic field should appear to be stable. No theoretician known to the author has a priori dreamed of such a configuration, to say nothing of contemplating its stability.

Bostick published photos and drawings of these weird shapes, which clearly delighted him. He was also able to produce plasmoids with forked tails and pairs of whirl-rings composed of helical twists, which moved away from each other in space, along magnetic field lines. He says that magnetic fields were trapped in these rings, but he was unable to 'explore' them further.

Finally Bostick enthusiastically reminded people of the possible cosmological implications of what he was discovering:

By firing simultaneously two or more plasmoids across a magnetic field, it has been possible to produce co-operative phenomena which not only simulate the production of spiral galaxies and astronomical barred spirals, but which permit us to study these processes in the laboratory.

In the discussion that followed and which was printed in the Proceedings, praise was heaped upon Bostick by various distinguished participants. Patrick Blackett (1897–1974), who was created Lord Blackett in 1969 and won the Nobel Prize for Physics in 1948 for his work on cosmic rays, said that Bostick's work had opened 'an extraordinary exciting new field'. Vincenzo Consolato Antonio Ferraro (1907–1974), a specialist in magnetofluid mechanics, said: 'This is an interesting and important paper.' And indeed it was.

Meanwhile the consternation of the military people might well be imagined. Bostick's plasmoids were behaving like mischievous imps. Everything they did was unpredictable. How could anyone ever control such wild things? They were almost as bad as people. And the essential thing for all those who are obsessed exclusively with defence requirements is always control.

### Going public

The publication in late 1957 by Bostick of his article entitled 'Plasmoids' in *Scientific American*, the widely read magazine that acted as a bridge between scientists and the general population, brought these matters to the attention of the wider public for the first time. One might say that this was both the beginning and the end of public awareness of plasmoids, as the subject then vanished, and no meaningful or sustained public discourse about plasmoids ever really occurred afterwards. There was a flurry of brief press articles in newspapers all over America reporting that a scientist named Winston Bostick had discovered strange things called plasmoids, but after Bostick ceased to be news, this stopped. And no one 'out there' seemed to 'get it'.

Plasmoids in the public sphere became merely a curiosity of the time, superficially reported, partially discussed in one major article by the man himself, and then, frankly, just forgotten. People's 'five-minute attention span' of which we hear so much today apparently already existed in the late 1950s.

It is worthwhile seeing exactly what Bostick did and did not say in his one genuinely 'public' article. *Scientific American* has always taken pride in having brilliant artists on their staff, who do absolutely superb illustrations

of almost any scientific subject. For Bostick's article, the magazine artists took his rather basic illustrations and turned them into spectacular displays. This did much to bring the subject vividly alive.

Bostick's Scientific American article commenced with this subtitle:

These little pieces of plasma (a gas of electrons and ions) are created in the laboratory with an electrical gun. They have an unexpected capacity for maintaining their identity

And on the very first page, there was a photo taken by Bostick of two glowing balls rushing away from each other and leaving luminous streaks behind, with a caption saying:

Two plasmoids are fired at each other in a vacuum chamber ... It can be seen that they repel and veer away from each other, so that each of the strange gaseous shapes retains its separate identity.

So the public got the idea right away that Bostick was making weird little balls of 'gas', which turned into entities of some kind. But what was this 'gas'? Bostick used his new word in his first paragraph: 'The gas is called a plasma.'

In this article Bostick paid tribute to Irving Langmuir, who had begun serious plasma research. It was Langmuir who had coined the term 'plasma' in 1928. Bostick wrote: 'The late Irving Langmuir of the General Electric Company began to study plasmas as long ago as 1921.' Bostick was fascinated by the work of his predecessor Langmuir, and took time to record Langmuir's ingenious experiments by which he was able to measure the temperature of the electrons in a neon light tube:

Langmuir measured the electrons' temperature and found that it amounted to about 20,000 degrees Fahrenheit – about twice as hot as the sun's surface.

This temperature of 20,000 degrees Fahrenheit is 11,933 degrees Centigrade. And yet that same neon light tube can be held in the hand and feels cool to the touch even when the electrons in the centre of the tube are twice as hot as the Sun's surface. This information is a crucial fact, which we will need to keep in mind when we consider plasmoid entities. Anyone who thinks plasmoid entities cannot contain within a very small space huge variations in temperature, pressure, charge, and complexity, need only remember the lowly neon light tube. That is proof enough that the sort of

complexity in plasma that we will be discussing as we go along is not only possible but probable.

Later on we will encounter such things as double-layer sheaths and spiralling filaments inside plasma cylinders. And we will see how very hot and very cold plasma can exist happily side by side (protected by their surrounding sheaths, which isolate those regions from direct contact with one another absolutely) in closely adjoining regions within cosmic dust clouds such as the Kordylewski Clouds. Complex architecture within a plasmoid or plasma cloud may be built up in this way with ease, contrary as that may be to our conventional thinking and experience.

Bostick returned again to the subject of galaxy formation:

Photographs of plasmoids in three dimensions show that as a plasmoid moves across the magnetic field it is twisted into the shape of a left-handed screw ... The tempting speculation is that the matter of our galaxies may have been formed under the influence of vast galactic magnetic fields of one predominant orientation, which gave our matter a left-handed bias.

He then describes another curiosity. In this instance, instead of 'mating', two plasmoids sometimes run away from each other. So, just as with humans, not everybody is attracted to everybody else, and there is such a thing as plasmoid rejection:

Under certain conditions our plasmoids form a pair of rings, which do not stay in the center of the chamber but move away from each other in opposite directions ... our plasma rings are not whirls in a fluid but are separate, independent 'bodies'. As such they represent a form of ordered organization by nature of which we have not been fully aware until now. Here is a case of electrons and ions collaborating with a magnetic field to form bodies which, though inanimate, assume orderly, characteristic shapes and possess a firm integrity.

This should remind us of the plastic microspheres in oil that were described in Chapter 3, which mimicked the behaviour of swarming bacteria and appeared to be 'alive' when subjected to electric field pulses.

The lessons to be drawn from Bostick's work have still not been fully realized. As early as the mid-1950s, it was perfectly obvious that 'separate, independent bodies' with 'ordered organization' and 'firm integrity' had been created in a lab from plasma. And yet, no one dared to imagine what has become clear only in the last few years, namely that these plasmoids can become even more complex than our physical bodies.

## Plasma Comes Alive

In this chapter, I am going to bring together arguments to show that dusty plasma in space can – and probably has – evolved life and intelligence.

The phenomenon of a burning candle illustrates the significance of dust. We have all seen burning candles, but how many of us realize that the flame of the candle is a small plasma? And why is the candle flame yellowish? That is because of the tiny particles of unburnt carbon dust (soot) embedded within the plasma, which arise out of the wax or tallow as the candle is burnt. When they reach a temperature of incandescence, they burn with a yellow colour, and that colours the flame in the way that is familiar to all of us.

The temperatures of the tiny carbon particulates as they burn in a candle flame can exceed 1000 degrees Centigrade, and yet you can pass your finger through the flame without harm. This is another reminder of the highly complex natures of some plasmas, and that, as we mentioned at the end of the last chapter, extremely high temperatures can occur within them in pockets or isolated sections or bounded cells, while the surrounding plasma remains cool. If we do not realize and emphasize the extraordinary complexities that make these bizarre internal disparities of plasmas possible, we cannot understand the evidence that will continue to be brought forward as to how there can be – as some scientists are now claiming (and also myself in what I have said about the Kordylewski Clouds) – living, intelligent plasmas.

As plasma research progresses and becomes more and more urgent, while also becoming more and more bizarre, there are increasing numbers of experiments being carried out on what are called 'cryogenic plasmas', plasmas at extremely low temperatures such as we never encounter in normal life, which can only occur on Earth in scientific laboratories, or in tubes of liquid nitrogen or other substances made in laboratories (<a href="here">here</a>).

Scientists are creating plasmas and injecting them into substances at extreme low temperatures, such as liquid helium, to see what happens. Liquid helium is so cold that its temperature is approximately minus 269 degrees Centigrade or minus 452.2 degrees Fahrenheit. At those low temperatures, a different temperature scale is used, known as the Kelvin Scale, named after a Scottish scientist named Lord Kelvin (1824–1907). Using that scale, liquid helium has a temperature below 4.2 degrees Kelvin, also written 4.2 degrees K. The Kelvin Scale is a purely scientific temperature scale, which sets 0 at what is known as 'absolute zero', which we never encounter in daily life.<sup>2</sup>

Surprising differences occur in 'high temperature liquid helium plasmas', which are near to 4.2 degrees K, and 'low temperature' ones, which are much closer to absolute zero. Different phenomena appear at the different temperature ranges, and no one really understands all of that yet by any means. The reason I refer to these cryogenic plasmas at this point is because in 2005, a team of Japanese scientists funded by the US Government's Asian Office of Aerospace Research and Development (AOARD) made an astonishing discovery.

They found 'unexpected high temperature of charged carriers' in the plasma,<sup>3</sup> meaning that surprising temperature variations can occur within plasmas, even when these occur within host plasmas that are very near to absolute zero. This is far more extraordinary than being able to hold a neon light tube when it contains electrons that are twice as hot as the surface of the Sun; this is like finding a patch of heaven that is deeply embedded in hell.

Let us recall that it was only in 1941 when Lyman Spitzer suggested for the first time that the huge clouds of interstellar dust that astronomers had observed for a long time through their telescopes might not be inert and useless stuff, but might be capable of becoming active and be charged dust. He said that negative electrical charges could be transferred to the dust by electrons in what he still called 'ionized gas', by which he meant what today we call plasma. Spitzer was making a tremendous conceptual

breakthrough, and today electrically charged dust is a subject of such importance that it is talked about every day by scientists and technologists all over the world.

That is not because they are all trying to figure out the Universe. There are more practical reasons. The dust that occurs within plasma is of crucial importance in the electronic microchip manufacturing business (where too much dust in the plasma interferes with the deposition of circuits onto microchips) and also – as we have seen – in connection with attempts to control nuclear fusion for power generation. It is no exaggeration to say that trillions of dollars are at stake on matters concerning dust, how to understand it, how to deal with it, and even how to use it.

The following year, in 1942, Hannes Alfvén, some of whose breakthroughs we examined in Chapter 8, discovered the 'band structure' of the solar system and was able to demonstrate that electromagnetic forces associated with a dusty plasma cloud (from which the solar system was formed) must have been dominant over the more usually mentioned gravitational forces in the formation of the solar system by contraction and solidification from – you guessed it! – dust. And that dust would have been electrified dust. Electromagnetic forces are so much stronger than gravitational ones that they exceed the latter by a factor of 10 followed by 39 zeroes.

By 1954, Alfvén had elaborated his ideas further and insisted that the planets and comets of our solar system (and by implication those of all other solar systems) were all formed as a result of the coagulation of dust particles in the solar nebula (the 'dust cloud' surrounding the early Sun) as a result of being electrically charged by plasma. (The dust was more important for the solid planets, of course, since the giant planets largely consist of plasma that is not solid.)

Many plasma scientists now suggest that stars form initially from dust. What happens is that the charged dust in a large plasma cloud in space coagulates to form a dust ball, which constitutes what is called a protostellar core, around which more of the cloud slowly collapses until a star is formed.<sup>4</sup> This would seem to be a variation on the Biblical injunction, to the effect that: 'Remember, oh Sun, that charged dust and plasma thou art ...'

Wouldn't it be amusing if the centre of our Sun was really a cold compressed dust ball?

As mentioned earlier (Chapter 3), in August of 1981, the satellite Voyager 2 took photos of the rings of the planet Saturn, and the rings were seen to contain mysterious radial shape-shifting 'spokes'. The scientists Jay Hill and D. Asoka Mendis in 1982 suggested that these 'spokes' consisted of charged dust, which was charged in a plasma. This was the first major invoking of charged dust to explain a solar system anomaly that had been discovered on another planet, and greatly raised the profile of dust within the scientific community. The suggestion was later amplified by Christoph Goertz and Gregor Eugen Morfill in 1983, who suggested that the charging was caused by plasma bursts on Saturn.

In 1986, Norman R. Bergrun published a book suggesting another theory about the rings of Saturn, involving an extraordinary theory connected with ET. Some information about that may be found in the footnote. It is very far from being a purely scientific theory.<sup>5</sup>

We saw earlier that in 1986, Hiroyuki Ikezi predicted that plasma crystals, known as 'Coulomb Crystals', could be formed by dust particles in a plasma. The existence of such crystals was announced at a conference in 1993 by Hubertus M. Thomas and Gregor Eugen Morfill, and in 1994 simultaneously published by three separate teams, consisting of Thomas and Morfill, Jiun-Haw Chu and Lin I, and Yasuki Hayashi and K. Tachibana. At this point, dust reached a new high!

Much of the dust in outer space actually takes the form of what are called dust grains. They are miniscule, but more solid than the kind of thing we are used to in the form of household dust.

How much dust and dust grains is there in the Universe, in proportion to everything else? According to the physicist Douglas C.B. Whittet, author of *Dust in the Galactic Environment*:

... submicron-sized solid particles (dust grains) ... account for roughly 1% of the mass of the ISM [interstellar medium] ... Despite their relatively small contribution to the total mass, the remarkable efficiency with which such particles scatter, absorb and radiate starlight ensures that they have a very significant impact on our view of the Universe. For example, the attenuation [weakening because of distance] between us and the centre of the Galaxy is such that, in the visual waveband, only one photon in every 10,000,000,000,000 reaches our telescopes. The energy absorbed by the grains is re-emitted in the infrared, accounting for some 20% of the total bolometric [bolometers measure luminosity] luminosity of the Galaxy.<sup>6</sup>

(Luminosity is a measure of the absolute brightness of something such as a star, as opposed to its apparent brightness, which may be diminished by distance and our atmospheric interference.)

Since we know that more than 99 per cent of the Universe consists of plasma, what little solid matter there is seems to exist primarily in the form of solid dust particles and grains, most or all of which floats in the vast plasma clouds. That reduces even further the amount of 'solid matter' of the sort that we see around us every day here on Earth, and it makes planets and moons even scarcer than we had thought, in terms of proportion of what exists, compared to everything else. That does not mean that there are very few planets and moons, quite the contrary, for we now know that there are untold billions of them. But what it means is that no matter how many there are, they still form a negligible proportion of what exists.

I do not believe anyone has calculated how much solid matter is left, after you subtract the plasma-bound dust. But as we face these facts, our familiar world is shrinking in significance all around us in the most drastic fashion. And, as I have already pointed out, if we have a science that is entirely based upon living in an atypical world, our science is going to be atypical. So we must reform it at once!

# Are some plasmas alive?

We have been following the observation and testing of the influence of electromagnetic fields in the work of Langmuir, Alfvén, Kapitsa, Bostick and others. Plasmas are bounded entities that persist through time, a characteristic of any living organism at the most basic level.

Plasmas may feed on fresh plasma, and be nourished, for example, by solar winds. They may even compete for such food. Plasmoids seem to bond with one another and interact in other ways

We have seen particles in plasmas swarming like microbial beings (Chapter 3) and forming other patterns such as hexagonal structures, spirals, concentric circles and double-helix patterns (Chapters 2, 3, 11). Nerve-like filaments grow in plasmas, including those that form double helixes and may carry information as well as energy. Plasmas seethe with movement in and around their own internal structures created by electromagnetic fields. Complex plasma entities have countless plasmoid regions within them, all

protected within their sheaths and separated by 'voids', like organs in animal bodies.

Some contain hot plasmas, some cold plasmas, some dusty plasmas, some non-dusty voids. Some containing impurities that may hinder or accentuate the flows of charged currents in the manner of electronic semiconductors and transistors. In other words, large plasma clouds are bound to have the equivalent of semiconductors scattered throughout themselves, in order to modulate the current flows.

We have seen in the work of Peter Kapitsa that the crystalline structure of complex dusty plasmas makes them potentially far more complex than human bodies. There are soft, broadly crystal-like structures that grow into beautiful and intricate entities with the ability to transmit information over vast distances. Particles within a plasma can interact in concert with other particles.

Furthermore, and as we shall see shortly, the mysterious ability to move through objects without changing form, seen in quantum mechanics in the phenomenon associated with solitons and sometimes called 'tunnelling' takes place between 'organs' in a plasma. We will return to this later, when we will explain 'tunnelling'.

There is no universally agreed, mathematically precise set of defining qualities of a living entity, but most accounts include growth, cellular form, reproduction, response to stimuli, ability to receive and process energy.

Of course, living beings that are not carbon based like ourselves will not be alive in exactly the same way that we are, but will be 'alive' none the less. We met Vadim Nikolaevich Tsytovich in Chapter 3. We mentioned that this leading Russian researcher into plasma and collaborator and co-author with Nobel prize winner V.L. Ginzberg in the 1970s, wrote in 2007 that the principles used to define life are:

autonomy evolution autopoiesis [a system capable of reproducing and maintaining itself]

#### He concluded that:

complex organized plasma structures exhibit all the necessary properties to qualify them as candidates for inorganic living matter that may exist in space provided certain conditions allow

### Are there intelligent plasmas?

What are the defining qualities of an intelligent, living entity? For a plasma to count as intelligent, and with an intelligence that involves features a bit like our own – for example memory, the ability to perceive, communicate, model, choose, predict and manipulate reality. For that you may need a much greater level of complexity. You probably need a series of interdependent systems with both internal and external functions, plus an overarching system that coordinates the smaller systems.

In Chapter 5 we saw that plasmas in the form of ball lightning appear to act intelligently – or at least to operate by an intelligence. We saw how they appear to navigate, following aircraft or submarines – they know which way they are heading – turning at right or other angles, being still and then suddenly moving away at vast speeds, and even rolling down the aisle of an aircraft as if on an inspection visit.

Kapitsa's discovery of the crystalline structures in some complex dusty plasmas, discussed in Chapter 5, and the realization growing from that and based on the analogy with crystals in metals, suggested to me that it may be possible to calculate the density of electrons within a plasma. I realized immediately that this density could be crucial when calculating the likelihood that intelligence might evolve in a plasma.

This was much on my mind when I approached my friend, the mathematician and astronomer Professor Chandra Wickramasinghe, who like me was a friend and huge admirer of Fred Hoyle's and had been mentored by him; Fred supervised Chandra's PhD and they co-authored numerous works. Chandra and I agreed to cowrite an academic paper on the Kordylewski Clouds (KDC), considering their potential to evolve intelligence. What follows is an edited extract with the maths removed. The full paper can be found as Appendix 1:

The Kordylewski Cloud at the point in space between the Earth and the Moon known as L5 (the 'L' stands for Lagrange) has a density over a hundred times higher than the density of ambient interplanetary dust. The maths shows that the mean distance between neighbouring particles within the cloud is thus very short indeed, yielding the possibility of inter-particle 'communication' if electromagnetic signals can be exchanged.

This could be made possible because the dust would be charged to a potential of a few volts because of the photoelectric effect caused by absorption of solar ultraviolet photons; and collisions with ambient gas would lead to rotation (spinning) at radio frequencies. Spinning charged grains, particularly those in the form of elongated needles typified by bacilli, would be efficient absorbers and emitters of electromagnetic radiation. [This production of radiation because of spinning is explained more simply in a moment.] Most interestingly the total number N of such charged dust particles in a KDC (distance of < 1cm apart) would be truly vast.

With electromagnetic-wave emission/absorption across cloud dimensions as well as electrical connections (charge/current exchanges) between adjacent charged particles only centimetres apart, a Kordylewski Cloud might well be able to function as a gigantic computer/brain capable of storing and processing digital information. The maths also shows that the cloud may have a super-astronomical sum total for its potential computing power, exceeding the computing power available in all human brains, and indeed all other intelligent life on Earth as well, by very many orders of magnitude.

Finally, we refer to a few of the remarkable features that are known to characterize dusty complex plasmas and which could also play a role. The nucleation and growth of dust within such plasmas have been documented in several laboratory studies. In our case, however, the dust nucleation process will be side-stepped, and condensation within Kordylewski Clouds is likely to occur upon pre-existing interplanetary, potentially biological, dust particles. Thus, we could envisage a population of bacterial particles coated with semiconducting siliceous mantles that may well enhance interparticle electronic connectivity. Such speculations may sound far-fetched, but they lie within a broad framework of possible outcomes based on known behaviour of complex dusty plasmas.

We might thus be tempted to view Dust Balls as highly structured 'intelligent' systems capable of storing and processing 'information' and realize that they may have many more surprising and unexpected features. Indeed, such huge stable entities that have presumably endured for astronomical timescales and have steadily grown in complexity over billions of years may display spontaneously evolved phenomena resembling those of the most highly complex living entities.

This situation is not dissimilar to the brain-like like complexity of the 'cosmic web' discussed by Ginsburg et al. (2019), although it is potentially even more impressive in its computational potential: the Dust Balls would contain an intricate combination of charged dusty plasma in gaseous, liquid,

and crystal states, with regions of positive charge and regions of negative charge separated from each other by sheaths and double layers, and containing superconducting filaments, so that it would be difficult for us to speak of a Kordylewski Cloud as a whole being singly charged or having a total net charge (or zero net charge), since there would be so many multiple regions of varying charges that a total net charge for each cloud would only be relevant when speaking of the cloud externally, such as in relation to the solar wind which is known to be predominantly positively charged.

Readers may still be wondering how such a seemingly tenuous structure as a Kordylewski Cloud can possibly hang together ('cohere') and become so incredibly complex?

Space is full not only of dust, but also of elongated grains (not unlike rice in shape, or we may think of them as rods or cylinders), which can be as large as one micron across. A micron is also called a micrometre. It is one millionth of a metre. (The next smallest measure is a nanometre, which is one thousandth of a micron, in other words, one billionth of a metre.) So don't think you can ever actually see a 'space grain' with your eyes, as a micron-sized one is the largest, and most are even smaller.

It is dust spheres and elongated dust grains of this size that constitute the 'bodies' of the Kordylewski Clouds, and they are much too small to be detected by satellites that might ever pass near or through the clouds. But the clouds are so gigantic that there are trillions upon trillions of trillions of these constituents within them; they can be very diffuse by our standards, in other words, very far apart from the point of view of our own bodies, so diffuse as to seem almost not to exist at all. After all, at our human scale, we think of the atoms constituting our bodies as being very near to each other. Of course, the idea that our bodies are solid is an illusion: Sir Arthur Eddington asserted a century ago that all atoms consist of 99 per cent empty space; nowadays we might modify that to say 99 per cent an amorphous mist of tiny, tiny particles called quarks and gluons.

The point is that if you shrank to the size of a 'space grain', you would find that you could easily traverse an entire human body and see nothing substantial because everything of which it was constituted was too far apart to appear to consist of anything. In other words, we would all essentially be undetectable. So everything is a matter of scale. If you were the size of a Kordylewski Cloud, you would very readily see them. You have to be big enough to 'see' them properly, or to have technology that can reveal them, as ours has done, but with difficulty.

Some of the dust grains are elongated rather than spherical, which generates the forces that are needed. That is because the space grains are each rapidly rotating, or as we can also say, are spinning. (This is no connection with the entirely separate subject of 'quantum spin'.) These rotations generate low-frequency waves in the plasma, some of which have colourful names: 'the electron whistler', 'the dust whistler' and 'dust cyclotron waves', Alfvén waves, and 'electromagnetic ion-cyclotron waves'. Many of the dust grains are essentially levitated by electromagnetic forces.

The space grains are set spinning by electrical fields. But they do more than rotate. They also 'quiver' and 'bounce', to use the very words actually used by the plasma scientists who published these findings in 2002. The idea of invisible spinning, bouncing and quivering rice grains floating around in outer space and 'whistling' may seem like some science fiction fantasy, or somebody's idea of a practical joke. But it is all true. As the scientists say: 'The dust grains execute bouncing motions ... Furthermore, each grain also performs transverse quivering across the sheath electric field ...'

The energy of the dust rotation can flow into the surrounding plasma and generate plasma waves. The grains are magnetic dipoles, meaning that they have positive and negative poles. They are charged either negatively, by thousands of electrons clinging to each of them, or positively by protons and ions clinging to them. And those charges are directly coupled to the electric field in which the dust grains reside. It is obvious therefore that these spinning grains are generating collectively a great deal of energy that pours into the surrounding plasma. As a result, microwaves are emitted and it has been proved that 'Coulomb Crystals' (crystalline structures that can sustain themselves and remain differentiated from the plasma sea) can form, thus creating the elements of macro-sized structures, compartments, and 'pods' within the plasma cloud.

So we see that it is the spinning grains that generate the energy to form structured clouds, as if they were a vast army of microscopic power generators, which 'create' the organization of the whole cloud. The number of spinning grains inside each Kordylewski Cloud could be as many as 10 followed by 26 zeroes. As we point out (see <u>Appendix 1</u>), the electrical connections and current exchanges between adjacent charged grains, even if they are as much as a centimetre apart in a Kordylewski Cloud, would create a structure that might well be able to function as a gigantic computer/brain capable of storing and processing digital information.

Having described the spinning micro-generators inside the clouds, I will now clarify a strange fact about dusty complex plasmas that makes all of this possible. I am going to quote a few words from the plasma scientists Dietmar Block and André Melzer in a paper they published in 2010, but first I need to explain that scientists have a term for describing elements of a system, such as particles, which have powerful interaction energies holding them together. They call this 'strong coupling'. (Think of a happily married couple who stick together for decades.) Block and Melzer mention how 'strong coupling' works in 'normal' solid matter, which consists of atoms with very small inter-particle distances. Then they say:

In dusty plasma the situation is different. If micrometre-sized particles are immersed in a plasma environment they immediately attain high negative charges due to the higher mobility of the electrons ... Therefore, even at particle distances of the order of several hundred micrometres the mutual interaction energy of two particles exceeds by far their thermal energy and the system is strongly coupled ... At the same time this strongly coupled system has a fairly low particle density ... and a favourable ratio of interparticle distance to particle radius ... This combination results in a very high optical transparency [i.e., it is almost invisible], which allows us to observe individual particles even at the centre of clouds containing more than  $10^6$  [the mathematical way of writing 'one million'] particles.<sup>8</sup>

Just think what this means if translated into human terms. If we speak of human beings instead of particles, it means that if there were one million people standing together in a vast crowd covering a huge area of land, they would have to be so far apart from each other that even at a distance we could with a telescope distinguish and detect every separate individual. This brings the common phrase 'you are one in a million' into sharp focus!

This is what a dusty complex plasma is like. Every single particle is 'one in a million' and can be individually detected in principle, and yet this vast and seemingly tenuous grouping constitutes a powerful structure, unified, coherent and immensely complex, bound together with overwhelming invisible strength and powerful forces. For us feeble humans, who are not

used to thinking of such things, we are like the public at the time of Copernicus (1473–1543), who simply could not imagine an Earth going round a Sun. This is how fantastically different thinking about dusty complex plasmas is from anything with which we are familiar in our lives.

An analogy here on Earth would be if we were to claim that the ocean is a giant brain. Well, it is not. That is because it is here on Earth, is made of atoms, and is physical matter. This is how different plasma really is. With dusty complex plasmas, a tenuous and essentially invisible cloud in space can hold together and become a brain even bigger than an ocean, a brain so gigantic that it is many times larger than our entire planet. We have to get used to thinking like this, and to realize that these clouds in space are so different from anything we know in our lives, or anything we could have imagined, that all of our conventional notions are completely useless.

Another crucial thing to realize about plasma structures is that they maintain their integrity by means of something called the double layer, also sometimes called a bilayer, which has helpful electromagnetic properties.

Two different plasma regions of entirely different kinds can be rigorously separated from one another by these double layers. The double layers are like a double skin, being a sheet of positive charge on one side and a sheet of negative charge on the other side. For those familiar with microbiology, they are similar to the double layers that occur within our own physical bodies as walls of cells, called membranes, with a hydrophilic (waterloving) surface facing one way and a hydrophobic (water-hating) surface back to back with it and facing the other way.

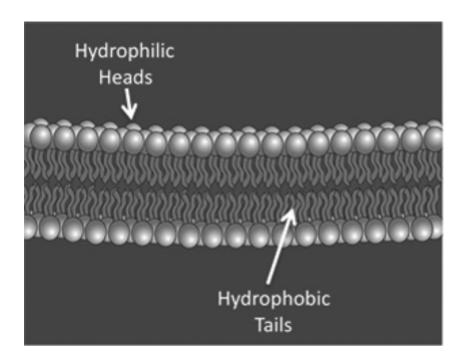

Figure 23. A typical double-layer cell membrane within a human body. Such membranes are analogous to the double layers that exist in plasma, and which surround the plasmoids and all the current-carrying filaments inside plasmas. Unless organic cells are protected by these walls called membranes, they cannot exist. The outward-facing parts of the membranes are hydrophilic, meaning 'water-loving' heads, and hence friendly to the watery environments of the cell and body. The inward-facing parts are hydrophobic, meaning 'water-hating' and they just hate being exposed to water. This excellent image comes from a course in Anatomy & Physiology, Bio 264, Cell Membranes section, at Brigham Young University, USA, and may be viewed at https://content.byui.ed. This is a simplified image of the basic structure of a cell membrane, although in reality there are often various 'plug-ins' sticking through and pathways for biocurrents such as flows of protons and ions across the membrane. In this book it has not been possible to take the space to discuss all those phenomena, for the discovery of which Peter Mitchell was the brilliant pioneer. (By showing how currents flowed through membranes, he totally changed the previous view of metabolism as being a static chemical process, known as 'the Bag of Enzymes' theory. He replaced that theory with the true description of what really happens, which is often called Vectorial Metabolism, meaning that metabolic processes are like vectors and have a direction in space, which is far from the random processes of chemicals sitting idly in a 'bag of enzymes' like loungers on adjoining deck chairs who might occasionally have a chat or a joke.)

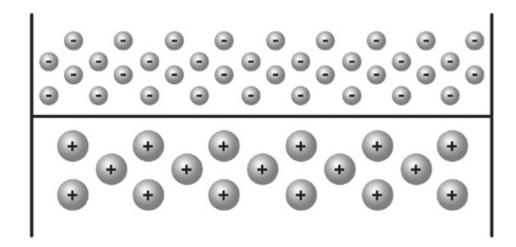

Figure 24. An electric double-layer. At the top of the diagram, the rows of small circles enclosing minus signs represent electrons, which are negatively charged. (The minus signs mean 'negative'.) At the bottom of the diagram, the rows of larger circles enclosing plus signs represent protons, which are positively charged. (The plus signs mean 'positive'.) Combined in this way in a double-layer, the electrons and the protons form a protective sheath which enables a blob of plasma to be protected from whatever is going on outside, and therefore to remain intact 'come Hell or high water'. Such a blob can cohere and retain its integrity no matter what surrounds it, blasts rays at it, or tries to destroy it, up to a limit which is usually very high indeed. Without protective sheaths, such plasmoids and other plasma blobs, filaments, and entities would be rapidly destroyed and could have only a momentary existence. It is clear that the same basic underlying principle is at work in the double-layers of organic cells and the double-layers of plasma blobs (or 'plasma cells' as we might well call them). In other words, the principle of the double-layer surrounding wall seems to be a universal structural element found in both organic and inorganic natural phenomena, as a means of enabling entities to maintain their identities within hostile or stressful environments. (Image drawn for the author by Eric Wright.)

So to refine what we said earlier about the roles of sheaths, crystals and voids in plasmas, it is partly because of these double layers that vastly differing regions can exist within a plasma body, practically side by side. For instance, you can have an extremely hot interior of one plasmoid and an extremely cold interior of another plasmoid. As already discussed, they can be practically next to one another, but can coexist because of these double layers, which help isolate them entirely from one another. It is such double layers that surround the Birkeland Currents in space, which were discussed earlier, and which transport electricity across interstellar and even intergalactic distances. Within those filamentary structures, the current spirals can be superconductive, which means that the current can pass without loss over vast distances, and there is no resistance to cause it to diminish at all.

It is often said anecdotally that the human brain contains more neurons than there are observable stars in the night sky. But the human brain fits inside a small skull. A stable dusty complex plasma ball of immense size, which has possibly endured for aeons and experienced continual growth and expansion over countless millennia, is in principle capable of developing something resembling a much more complex nervous system than a human brain with its average lifetime of around a hundred years. A complex dusty Kordylewski Cloud that has existed for many millions of years might even have become self-aware, with all that this implies. It is conceivable that Fred Hoyle's fictional *The Black Cloud* has a reality in the context of Kordylewski Clouds – which, of course, he could not have recognized in 1957.

I would recommend Hoyle's science fiction novel to everybody, as it is a thrilling and scientifically based tale of cosmic menace and the race against time to save our species. In the book, a dark patch is noticed in space by astronomers looking through a telescope. It wasn't there before. How did it appear? What is it?

Over a period of time, the dark patch gets bigger and bigger. The conclusion is inescapable: it is headed our way! It gets more and more threatening as it gets closer. Eventually the astronomers notice that it is a gigantic cloud that emits no light, hence is a 'black cloud'. No one knows what it could possibly be. It must be stressed that this extraordinary anticipation of the existence of the gigantic dark and invisible clouds in space resembling the Kordylewski Clouds was published at a time when space was regarded as a vacuum, four years before Kordylewski reported his extraordinary discovery.

As the cloud gets closer and closer, the fate of the Earth and all its inhabitants is threatened, since the Sun's light will be blotted out. It is discovered that the black cloud is a huge intelligent entity with a gigantic brain (we might even think of it as a non-glowing plasmoid). Intelligent contact is established with the cloud, and Hoyle satirizes the political as well as scientific hysteria on Earth.

The public are kept uninformed for as long as possible, of course, since that is always official policy. And just when the Earth is about to be destroyed and everyone is prepared to die, something unexpected happens. The black cloud with its super-sensitivity to distant signals in space picks up a signal from very far away indeed in another part of the galaxy. It is another black cloud! So the black cloud, which is about to engulf the Earth (not intentionally, but because it is big and clunky), suddenly changes course and rushes off to find a new friend, and the Earth is saved.

Fred's novel brings up the obvious subject of communication with the Kordylewski Clouds. If the clouds are as intelligent as I am suggesting, then they already know all about us while we know almost nothing about them.

In conclusion, from Chandra's and my paper we can see that the particles in dusty plasmas such as the Kordylewksi Clouds can be close enough to exchange electric signals.

In Chapter 14 we will look at other great scientists who have developed ideas that can help us understand more clearly how intelligence in complex dusty plasmas might work, including Paul Dirac and David Bohm (1917–1992).

And we will look too at the role that quantum properties in plasma might have had, not only in the development of superintelligence in the Kordylewski Clouds and the development of quantum computers, but in human beings too.

# The Mysterious Case of the Dirty Gas

Our bodies are so covered with bacteria that there are ten million bacteria to be found on every square centimetre of our skin. Fortunately, most of them are friendly. And we thought maybe they stopped there, our skin being presumed to be the boundary of our bodies. But then we found out that things are not as simple as that.

In late September 2015, a flurry of news reports appeared in the media about an article that had been published in a scientific journal by Dr James F. Meadow, an American microbiologist then doing post-doc work at the University of Oregon, where his PhD was in Ecology and Environmental Sciences. He has now become the Lead Data Scientist at the law firm Dillon-Harrison's biotechnology service, Phylagen, in San Francisco's Bay Area.

In his article, Meadow reported the results of experiments he carried out with a group of people concerning the bacteria that he knew covered all human bodies. What he discovered was that the bacteria formed unique 'clouds' surrounding the bodies. His scientific report on his findings was published in the online journal *PeerJ*, on 22 September 2015, by him and six colleagues.<sup>2</sup>

The amazing findings revealed that people can be uniquely identified from their 'bacterial clouds', which are equivalent to fingerprints or iris scans. Everybody is surrounded by a cloud consisting of millions of bacteria. The exact sizes of these clouds have not yet been measured, but the clouds appear to extend for several feet beyond the body in all directions. When we walk around, therefore, we are really clouds of bacteria with a hard core called a physical body. As for the body itself, the cells within it and supposedly 'constituting' it are outnumbered by the

microbiological entities (bacteria, fungi, and viruses) living on it and in it by ten to one.

What this means is that only 10 per cent of the cellular components of ourselves are really what we think of as us, and 90 per cent is a cloud of microscopic parasites that follows us around. However, most of that 90 per cent used to be us, and was ejected. So if you follow the logic through, what this means is that 10 per cent of us is currently us, 90 per cent was us in the past, and thus we are in a sense made up of 90 per cent past and only 10 per cent present. Never in the course of human history has proof been so forthcoming that people really do come with baggage!

According to Meadow and his team, humans emit ten million particles per hour, which means that we emit 240 million particles per day, into the air around us. Upon learning this, it did not take me long to figure out that the sedentary lives most of us live today, compared to the lives of our ancestors who spent so much time outdoors having their bacterial clouds being buffeted and continually blown away by the winds and breezes, obviously means that the concentrations of our personal bacterial residues are much greater than those of our ancestors. If our houses are well-insulated and have no breezes or airflows, as older houses with open chimneys always had, then we are living daily in incredibly dense concentrations of bacteria, fungi, spores and viruses.

In Meadow's studies of microbial clouds, he specified that the particles in those clouds included also 'resuspended dust' and 'emission from clothing', so in order to eliminate clothing dust from his experiments as a variable, he had all his subjects wear the same clothes. The billions of microbes we emit may be harmless to ourselves, but not necessarily harmless to people visiting us. For they have their own clouds, which are not necessarily compatible with our clouds, and they may be vulnerable to the highly intensified microbial concentrations in our excessively insulated home environments.

The interactions of different people's bacterial clouds have not even begun to be studied, and neither is there yet a science of bacterial habitats for bacterial clouds, although microbiology is constantly producing studies of bacterial colonies on and within humans and on our cell phones, our computer keyboards, our doorknobs, and our TV remote controls. Getting nervous? You ought to be. The COVID-19 pandemic should have brought home to people by now the importance of what, during the epidemic, came to be called 'social distancing'. In fact, being six feet (two metres) apart from each other in order to avoid contamination of one another is a confirmation that forbidding our surrounding microbial clouds to touch can prevent us getting infectious viruses. The irony is that none of the medical authorities who recommended this social distancing appeared to be aware of the existence of our microbial clouds. They 'instinctively' knew that we must be six feet apart, and justified this by speaking of airborne droplets, or just because it 'seemed sensible'.

It is time they learned the full facts, which provide a sounder justification for their instinctive policies. The good news is that they pursued a sound policy in this regard anyway. Masks, however, make little difference to our microbial clouds and are pretty useless except in intensive care wards, because the viruses are a thousand times smaller than the smallest holes in the masks worn by the public during the pandemic. (Intensive care masks work, the ones made available to the public don't.)

Rather than speaking of 'bacterial clouds' we should more properly speak of 'microbial clouds', which include all species of entities emitted by our bodies at every moment of the day and night, and include fungi and viruses. And there is a close connection between these microbial clouds and dust, for a great deal of household dust comes from tiny bits of shed human skin, all of which carry bacteria on them, and those bacteria are carried off the body and then leave the skin flakes and float up into our microbial clouds and join in the merriment of 'being microbes together'.

Microbial clouds and dusty plasma are analogous in many ways as both are made of invisible and microscopic particles. And later in this chapter and the next I will be examining the work done on what are called our 'bioplasma bodies', which are invisible and which surround us, just as the microbial clouds do. The concept of bioplasma bodies suggests that we are jointly constructed of physical bodies and bioplasma bodies, which operate in synch.

The further suggestion is that when we 'die', because our physical body has worn out or been damaged beyond repair, our bioplasma body may detach from our physical body and abandon it to 'death'. We might be said to continue to exist as bioplasmic beings made of non-atomic matter – of

plasma. On this way of looking at it, the 'soul' is thus material, but in a different and more rarefied sense than was the physical body. This leads to the concept of bioplasma beings existing without 'physical bodies', and I suggest that this is what is often referred to as 'the Other World'.

Traditionally it has been called 'the spiritual world', upon the assumption that it must be wholly immaterial. It was assumed that body and spirit were entirely separate, one being 'material' and one being entirely non-material. I touched on this earlier, and it is what I regard as the prime fallacy of our Western civilization (as previously explained, it is not a fallacy that was ever traditionally adopted by the Chinese.)

But we must return to our discussion of the microbial clouds. What I want to raise as a question now is this: are the microbes in the clouds themselves charged? As we will see as we proceed, there are many researchers who insist that we have invisible counterpart bodies made of plasma (bioplasma) that surround us and extend several feet from us, so how does this relate to the fact that it has suddenly been discovered that there are invisible microbial clouds surrounding us?

Could and should we call our microbial clouds our extended bodies? And could our bioplasma bodies be continually interacting with our microbial extended bodies (clouds)? Or could they even be the same, with the microbes taking the place of the charged dust grains that one finds throughout space, for example, in dusty plasmas? And since all of those hundreds of millions of microbes that surround each and every one of us are alive, can they possibly all be coordinated by a plasma body that charges and energizes and forms them?

Even if the microbes themselves are not charged, there is sufficient dust accompanying the microbes within the clouds to make it reasonable to say that we are all perhaps surrounded by charged microbial clouds, if only on the basis of the accompanying charged dust that is within them. As for the effect of charge upon bacteria and viruses, I know of no experimental investigation of this that has ever been undertaken.

In a paper that is in preparation at the time of writing, I call for such experiments to be done. Things to be investigated include this question: if a virus is positively charged, does it act in one way, and if negatively charged, in another? We do not even have the answers to questions as fundamental as that. We have been through an entire pandemic without knowing whether

we could have intervened against the COVID-19 virus by the use of electric charge or magnetic fields. That is a shocking dereliction by the worldwide medical profession.

My own opinion is that COVID-19 viruses travelled on the winds in charged 'viral clouds' protected by sheaths, which explains why outbreaks were able to take place on cargo ships at sea, which had had no contact with anyone for six weeks. What makes such a viral cloud suddenly 'dump' may be connected with encountering powerful thunderstorms. The Earth itself is negatively charged, as all lightning experts will tell you. Ordinary rain varies in its charge. High rain is positively charged while low rain is negatively charged. Most people do not know any of this. Virologists should really be given crash courses in geophysics.

I would suggest that most or possibly all 'bacterial or virus colonies' are unified entities in some way, but that when it comes to microbial clouds, that must be true to a higher degree. If we all have invisible microbial clouds and also have invisible 'bioplasma bodies', and both surround our dense physical bodies and both are approximately the same size, then how could they not interact with one another? Is it possible that the microbes that stream off us at the rate of ten million per hour become charged by the 'bioplasma body', become subsumed within it, take on its shape, and lend substance to it? I do not see why not. Indeed, it may well be the microbes and dust continually sucked into our bioplasma bodies that enable our bioplasma bodies to function in relation to our physical bodies.

When scientists can figure out how to do so, the sizes, shapes, and configurations of our microbial clouds will surely merit close study. In addition, we will need to examine the electrical charges, whether positive or negative or both, of the microbes and the accompanying dust within our personal clouds, and, most important of all, try to determine whether the clouds have cellular internal structures. For if they do, that means that there are insulated pockets within the clouds that can contain microbes and dusts of highly varying characteristics.

For instance, there could be cloud-cells full of positively charged microbes, cloud-cells full of negatively charged microbes, cloud-cells in which toxins and pathogens are isolated, and charged double-layer boundary layers resembling membranes separating the cloud-cells from one another. In the event of ill health, such boundary layers might break down,

and pathogens that would normally have been safely contained get released. If we could determine such things happening, we would have early warnings of disease.

We should also urgently undertake investigations of the effects of aerosol sprays on our microbial clouds. They would in my opinion be certain to alter the ultra-weak charged currents in our clouds. But before we can even examine that, we need to know what kind of charge aerosol particles carry. Are they positive or negative? 'Charge' can be defined as 'a quantity of electricity or proticity'. 'Charged particles' are called particles because they are small. But they are called 'charged' because they have either a positive charge, like a proton or ion, or a negative charge, like an electron.

Positively charged dust particles and grains tend to be larger and slower moving than electrons. A positively charged dust grain can easily have 10,000 or more electrons adhering to its surface, like sperm chasing a single egg and irresistibly attracted to it. And yet no one appears ever to have thought about the charges that exist on aerosol particles, particle sprays of perfume or cologne, dust particles from talcum powder, tissue dust when we wipe our noses, and antiseptic sprays that fill most restaurant serving areas as the staff wipe the tables using a technique of 'reconnaissance by fire', i.e., first spray your way in, and then close with the enemy and wipe. (If the adjoining customers choke, ignore them.)

Ignoring all these sorts of things is a danger to public health.

I recommend the creation of a new scientific discipline, which could be called electro-microbiology. Scientists working in that field should attempt to study the charging of microbes and accompanying dusts. For instance, if you take a microbe and give it a positive charge, what is the difference between that and taking the same microbe and giving it a negative charge? How do groups, or colonies, of microbes behave when they are: (a) positively charged, (b) negatively charged, and (c) both? How do microbes of the same charge relate to each other? Of the opposite charge? And how do these interactions differ from uncharged interactions?

Putting aside the bacterial clouds, what about the human body itself? It is a little-known fact that one-fiftieth of our body weight is made up of bacteria that are inside or on the surface (skin) of the body, and these are all in addition to the ones in the clouds that are outside the body.

The number of bacteria living inside us is so great that our bodies contain 10,000 times more bacterial cells than actual human cells. And as for the surfaces of our bodies, as we have already learned, there are so many bacteria on our skin that approximately ten million bacteria live on every square centimetre of our skin. They mostly live in the outer layer of the skin, the stratum corneum, which is made up of dead skin cells. So the surfaces of our bodies largely consist of dead human cells filled with enormous colonies of live bacterial cells. The total bacterial biomass on the Earth is a thousand times greater than the total world human biomass. Earth is thus the planet of the bacteria, not the planet of animals and humans.

Furthermore, the bacteria multiply their numbers so fast that if we completely cleansed a patch of our skin of bacteria it would take less than twelve hours for them to grow back again to the same numbers.<sup>3</sup> And now we also know that in addition to that we are surrounded by clouds of further bacteria and microbes, as I have just described. So what does that make us? Our bodies are largely bacterial support, incubation and transport vessels. Fortunately, the majority of 'our' bacteria are beneficial to us, for otherwise we would have died out as a species long ago.

It is possible that most microbiologists of today do not know enough about plasma to realize that it acts as an excellent conductor of charged currents when there are imbalances of charge in the plasma, or when the plasma has a cellular structure, such as we find in the Earth's atmosphere or in dusty plasmas such as the Kordylewski Clouds. (As we have seen, cellular structure implies the existence of boundary layers, known as 'double-layers', surrounding the cells, and these layers themselves carry currents, often very powerful ones.)

If the microbial clouds around us are charged by plasma or become part of a plasma cloud, or even generate a plasma cloud through their own charges, then they can potentially carry electric currents, whether electricity (negatively charged currents) or proticity (positively charged currents). And of course, once you have electric currents, you get magnetic fields. We may thus be surrounded by highly complex ultra-weak currents and fields, the existence of which no one has ever suspected until now, at least not ones involving microbes and dust.

What is more, we cannot rule out the possibility that the toxic characters of some microbes will be cancelled out, or enhanced, by charge. And if there are electric currents and magnetic fields surrounding us within our charged microbial clouds, these too can have beneficial or harmful effects on us. I am inclined to suspect, however, that the average effects must be helpful, because otherwise how would we have survived throughout the ages?

The electric currents and magnetic fields that would thus occur within our microbial clouds would be what is known as 'ultra-weak'. This means they would be extremely hard to detect. 'Ultra-weak' sounds as if such currents and fields would be of negligible effect. However, there is a massive amount of scientific evidence concerning the crucial importance of 'ultra-weak' fields and currents in relation to the human body. Much of the work done in that field is furiously opposed by various corporate interests, especially those of the big power companies, because the studies largely are related to what is known as 'electro-pollution', a subject which 'Big Money' wants to hush up, because it threatens their financial interests.

It is not only that living beneath power lines is dangerous, which is something everyone can readily understand, but also the intense radiation produced by 5G poses great risks to people. However, that is not for discussion at the moment. I mention it here only to point out how overwhelming the evidence is that the human body is 'ultra-sensitive' to the 'ultra-weak', especially to what we will describe later as 'bio-photons', and indeed to any and all forms of electromagnetism.

We must not forget that the body itself is electro-magnetic.

The relevance of electricity and magnetism to the human body was revealed very dramatically in 1963, when Gerhard M. Baule and Richard McFee made the first scientific detection of a naturally occurring 'biomagnetic field' in the human body, and they proved the existence of a magnetic field associated with the action of the human heart. The electrical and magnetic aspects of the human heart are now universally accepted, but it was very painful and difficult for scientific and medical experts to accept this discovery at the time, because it went against the 'body as a machine' theory, by which everything was supposed to be chemical and mechanical. (Modern machines use electricity, but 'the body as a machine' theory did

not allow for that, and was essentially based on models of clocks and nineteenth-century factory machines.)

Pre-existing fixations, theories rigidly adhered to, ossified notions, and fixed opinions are the great enemies of progress in science; but scientists are human beings, with all the limitations that that implies.

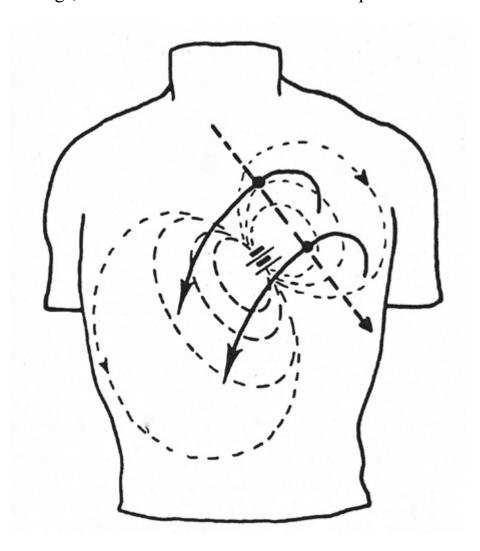

Figure 25. A diagram showing the electrical and magnetic activity of the human heart. The solid lines depict 'lines of force' with directional arrows, demonstrating that the heart's magnetic field travels from left to right across the human chest. The dotted lines show the electrical current produced. The artist has drawn a schematic small electric battery at the location of the heart to suggest the electromagnetic nature of the heart. From Gerhard M. Baule and Richard McFee, 1963 (see Footnote 4 to this chapter)).

Over the decade that followed Baule and McFee's findings, further understanding was gained, and in 1970, David B. Geselowitz (1930–2020)

published a preliminary paper,<sup>5</sup> and then in 1973 wrote a very lengthy technical account of the subject of the magnetic heart and biomagnetism,<sup>6</sup> in which he said:

The past decade has seen a dramatic improvement in the ability to measure biomagnetic fields. They are extremely small, about one million times weaker than the Earth's magnetic field in the case of fields of cardiac origin and even smaller in the case of fields originating in the brain. Hence, the detection of these fields has been a major experimental challenge. Nevertheless, it has been possible to develop instrumentation so that such fields can be measured almost routinely.

Figure 26. The magnetic field around the human head. The magnetic field goes from the left hemisphere of the brain around the head and back in through the right hemisphere. The 'lines of force' have been drawn to depict this, with the arrows showing the direction of the field. From Gerhard M. Baule and Richard McFee, 1963 (see <u>Footnote 4</u> to this chapter).

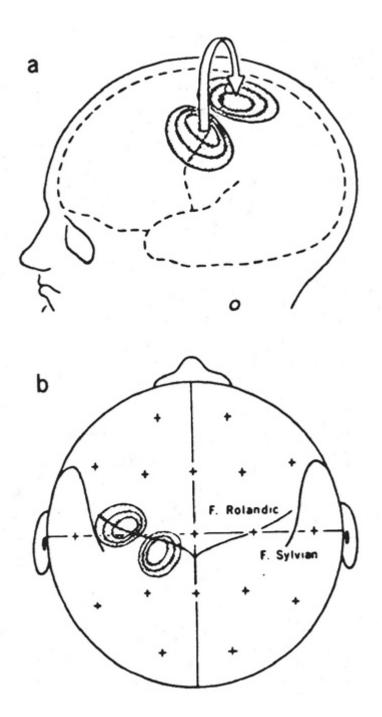

Figure 27. A separate magnetic field in the brain to that shown in Figure 26, and discovered subsequently. This field is sharply localized in a tiny region of the brain's left hemisphere – 'a': side view (with the arrow showing the field direction goes from left to right, as was the case with the field shown in Figure 26, and 'b': top view. This field is an 'evoked' field, created by shooting electric current into a person's finger! From Gerhard M. Baule and Richard McFee, 1963 (see Footnote 4 to this chapter).

These biomagnetic fields are crucial to our 'bioplasma bodies', as they continuously interact with our physical bodies through the actions of

electricity and magnetism. We will return to the revolutionary idea of bioplasma bodies in the chapters that follow.

## Electro-magnetic clouds around us

After I had written the above, Marco Bischof, an eminent Swiss writer working in Germany on the frontiers of science, sent me copies of all of the articles he had by Freeman W. Cope concerning the existence of superconductivity (which as we have seen, occurs when electricity flows without any resistance) within organisms, including our own bodies. It was originally thought that superconductivity could only happen at a temperature not far above absolute zero. Then it was discovered to be possible at higher and higher temperatures, and then it became common to suggest that it could happen at room temperature.

I had come across Cope's early articles in the mid-1970s and wanted to write about them at that time, but my literary agent and all potential publishers were scornful, insisting it was nonsense and that no one would be interested. Even to publish an article about it in a newspaper (and I was doing plenty of science stories for the media in the late 1970s) was impossible. There was a complete wall of steel erected in people's minds against the subject.

I will be returning to this later. I only mention it now in order to explain that I asked my friend Marco if he had any articles by Cope, the best-known researcher into the subject, which I did not already have. He sent me some, and along with those he sent five more by Cope on an astounding branch of study of which I had no previous knowledge. Furthermore, they came to my attention shortly after I had finished writing about electrified dust and microbes forming a cloud around the human body. Talk about perfect timing! It is those articles by Cope which I will discuss now.

Freeman Widener Cope was unquestionably one of the great pioneers of biochemical research. In 1982 he died rather young, aged only fifty-one or fifty-two, so that his work was tragically cut short. As far as I can determine, he spent his entire professional career working for the US Office of Naval Research, which as we have seen does all the secret work 'for the Navy' (really shared with the entire American security establishment) and is scientifically by far the most important of the four main American

defence security agencies. Cope was Head of the Biochemistry Laboratory of the Naval Air Development Center in Johnsville, near Warminster, Pennsylvania. All of Cope's work was funded by designated grants from the Office of Naval Research, officially acknowledged at the end of each of his articles.

Prior to his work on superconductivity, Cope had been engaged in wholly different routine work in the Biochemistry Division of the Aerospace Medical Research Department of the Bureau of Medicine and Surgery of the US Naval Air Development Center of the US Department of the Navy. He wrote a number of reports, and his Report No. 5, dated 2 July 1970, was declassified at some time subsequent to 1979, so that we can see what he was doing. The title of the report was 'Activation Energies of Acceleration and Hypoxia Stress'.<sup>7</sup>

Hypoxia is a deficiency of oxygen. He was studying the stresses imposed on pilots by rapid acceleration and oxygen deficiency. He concludes that 'moderate brain damage' may result and points out that 'tolerance to acceleration stress is not limited simply by the ability of the nervous tissue to endure hypoxia, but must be dependent upon additional mechanisms.' This shows that he was doing highly important 'normal' work concerning the health of naval pilots.

But then everything changed. Cope was taken away from his normal research and instead he remained until his death the Naval agency's special researcher into everything weird.

The Office of Naval Research does not exist simply to figure out how to stop ships from sinking and facilitate communications between submarines. It has a huge remit, which covers almost any scientific subject you can imagine, many of those subjects being very 'far out' indeed, beyond the known fringes of science. The Naval agency even joins with or competes with the Air Force agency to research the atmosphere! They are, of course, unaccountable to Congress for their budget, being 'secret'. All their scientists work under the most stringent security rules, have to sign many secrecy agreements, and can only publish what the agency permits them to publish.

And yet, out of this secretive milieu, not only did an amazing discovery come, but the people vetting publications actually permitted it to appear in

print. I suspect they realized their mistake too late, because it was not necessarily obvious at the time how much they were 'letting slip', and what the implications would be. I suspect they also must eventually have become nervous of Freeman Cope, who appears to have been an idealistic scientist, and the last thing a security agency wants is an idealist of any kind.

It is not easy to summarize briefly what Freeman Cope was proposing in his five revolutionary articles, because they cover complex matters to do with theories of electricity and magnetism, quantum theory, and some unfamiliar concepts of physics not normally discussed. But before I get to that, I must analyse how embarrassing the revelations of Cope really are regarding the Naval agency's files. This cannot have occurred to the censors at the time, for nothing explicit is said that could have breached Cope's secrecy agreements. It is only when all five articles have been read carefully, if one knows something of the background, that it becomes clear what was really going on, and why Cope became involved in this research in the first place.

For what had clearly happened was that the Naval agency had asked Cope to examine the seized secret papers of Wilhelm Reich and give his opinion as to whether there was anything to Reich's weird ideas. In other words, he was tasked with an evaluation of one of the stranger collections of scientific files in the agency's possession.

What seized files? Wilhelm Reich (1897–1957) was an Austrian psychoanalyst and one of the most brilliant students and protégés of Sigmund Freud (1856–1939). In 1922, he became the director of Freud's outpatient clinic. He began to develop ideas that went beyond Freud's, to do with the energy released in human orgasms. He began to speak openly of sexual matters and to promote more open sexuality in society. This caused a great deal of alarm in Vienna. He was also passionately anti-fascist, and he fled Austria for America in 1939. He lived there for the rest of his life.

But in America Reich caused even more alarm because he was speaking openly of orgasms, and as everyone knows Americans in the 1930s, 1940s and 1950s didn't have any. Reich's main interest in them was their release of a special kind of energy. He called this 'orgone' energy, and he regarded its release in orgasms as being only one of its many manifestations.

It was, in his opinion, a genuine universal life energy. Reich carried out many elaborate researches, attempting to find out what this strange

undefined energy really was. He came to believe that most of it appeared to come streaming in from the Sun, so he viewed it as part of what came to be known as the solar wind, but he believed it was not light, or electrons or protons or ions. It was something else, he did not know what.

Reich's theory of 'orgone energy' was that it was the essential life energy of all living beings, and that the sexual orgasm was a specific form of a general biological phenomenon (occurring in all creatures in different forms and for varying purposes, but found in specialized form in humans sexually) to do with 'an involuntary contraction and expansion of the total plasma system' resulting in an 'energy discharge', in which a bit of the orgone energy was released. He believed that orgone energy could occur in the form of tiny particles, which he called bions. Reich had concluded:

that every living organism is a membranous structure that contains an amount of orgone in its body fluids; it is an 'organic' system. Thus, the term organe comes from 'organism' and 'orgasm', and means an energy found within all organisms and basic to the orgasm reflex.<sup>8</sup>

Because he was a protégé of Sigmund Freud, Reich emphasized the sexual part of this theory, causing a certain amount of hysteria amongst many people who did not like open discussion of sex at all. Reich had published his book *Die Funktion des Orgasmus* (*The Function of the Orgasm*) in Vienna as early as 1927, carrying forward Freud's theories of the sexual energy called libido. Reich was not a physicist, and parts of his research were rather amateurish. Despite this, he made some significant and important discoveries.

He also designed 'orgone accumulators' to capture and store the orgone energy. At the time, there was no explanation for how they worked, and most people naturally assumed they were a fantasy and that Reich must be a madman or a charlatan, or both.

But there were some people who knew that Reich had stumbled onto something. It is necessary to give some of the political background to this, as one of the side effects of what happened was to suppress for many decades any public discussions of plasma, especially of cosmic plasma and any plasma or electronic functionalities within living systems. In Chapter 14 we will see related actions by the same people to suppress the work of the Nobel laureate Albert Szent-Györgyi, who like Reich had sought refuge in America. All these actions were part of the same systematic pattern of

persecution intended to prevent public awareness of certain sensitive issues that many immigrant scientists imported into America after the Second World War for defence and security work.

It was in 1947, the year of the formation of the CIA, that a campaign to attack and discredit Reich commenced. That was at the same time that Nazi scientists were being brought to America at the instigation of Allen Dulles, who in the 1930s had been employed by the Gestapo's front organization in America, the American subsidiary of I.G. Farben (famous as the manufacturer of the poison gas that killed the Jews in the death camps). He had also refused to act to save the lives of Jews being killed by the Nazis, of which he was informed at least as early as 1942.

In 1944, Dulles simulated horror at pretending to hear about the holocaust for the first time, whereas he had known all about it for at least two years, and had not only refused to do anything to stop it, but prevented others from acting. The shocking details of Dulles's lies and duplicity in relation to this issue of the genocide of the Jews are documented by David Talbot of the *New York Times* in his book *The Devil's Chessboard: Allen Dulles, the CIA, and the Rise of America's Secret Government*, published in 2015.<sup>9</sup>

Dulles was a close friend of Hitler's banker, Hjalmar Schacht, President of the Reichsbank, who had created a thriving economy in Germany, which enabled Hitler to go to war. Dulles was also a close friend of the American traitor Tom McKittrick, a former New York banker, who in his role as head of the Bank of International Settlements (BIS) at Basel in Switzerland (very near to Bern, where Dulles was based after November 1942) treasonously laundered stolen gold for the Nazis and obtained foreign currencies for them to enable them to buy essential war materials, such as the tungsten from Portugal and the oil from the Ploesti oil fields of Romania. McKittrick even went so far as to receive many tons of gold from the Nazis that he knew to have come from the teeth of Jews murdered in the death camps. <sup>10</sup>

Later, Dulles was to defy direct orders from President Truman about bringing SS men to America in defiance of American law. One can probably attribute to Dulles the origin of the CIA's traditional arrogance, its certainty that it knows best, and its contempt for mere presidents. In other words, we may probably regard Allen Dulles as the founder of what has come to be called by the name of the Secret State. Certainly the partiality of Dulles for the Nazis is well established, and authoritarianism seems to have been institutionalized within the CIA, an organization in which love for democracy seems to be in short supply.

As Talbot says of Dulles, viewed from the perspective of 1942: 'He was running his own foreign policy,' and from the perspective of today: 'Dead for nearly half a century, Dulles's shadow still darkens the land.' 11

After the war, Project Paperclip, and other similar projects with different names, got properly organized, and the American security establishment was being powerfully manipulated by the imported Germans, some of whom went straight into important positions. Many of them went to work for the US Army, Navy and Air Force security agencies. (The Air Force was formed for the first time in 1947, having previously been a branch of the Army.)

It was easy to attack Wilhelm Reich, who was a highly eccentric loner. Reich was arrested, his orgone accumulators were hacked to pieces with axes by FBI men in front of his eyes, their remains burned, and there were two book burnings of many tons of his published works. This was ironical, because Reich's books had been publicly burned on the orders of Himmler's SS in Austria years before, and now here were the American imported SS men doing it to him again, with the aid of their FBI colleagues. Yes, this really happened in the United States, 'the land of the free and the home of the brave'.

The SS men also violently hated Wilhelm Reich for his anti-Nazi 1933 publication *The Mass Psychology of Fascism*, in which Reich was merciless in attacking Hitler and the Nazis. And he hits home with pungent personal observations about Hitler, such as this one: 'He assures us that only once in his life did he cry: when his mother died.' Such critical observations about the Führer would have enraged the Nazis, for Hitler was meant to be the ultimate superman, capable of feeling and sharing all the emotions of his people (*volk*).

To make things worse for himself, in 1946 Reich's Orgone Institute Press published an English translation of that provocative book, which until then had been available only in German, though most copies had been destroyed by Himmler. It was effectively a public slap in the face to Allen Dulles and

his friends, and to their entire policy of bringing large numbers of SS officers to America and putting them into positions of power and influence at the heart of the American security establishment.

In fact, in June of 1946, Dulles went further and helped to arrange for the Eastern Europe and Russia wing of the Nazi security apparatus to be transferred lock, stock and barrel under its leader Lieutenant General Reinhard Gehlen (1902–1979) into a spy organization called 'the Gehlen Org' funded by the United States and ostensibly under American control, which was absorbed into the CIA following the CIA's formation in 1947.

With all this going on, Wilhelm Reich was considered a very dangerous enemy, lest the American public come to know that the Nazis now secretly composed the entire Eastern wing of America's foreign spy service, not to mention all those many Nazis who were being brought to America to work on American soil in the most secret projects such as mind control, and of course in the development of rockets and missiles.

But burning Reich's books was not all. Reich was committed to prison and mysteriously died there not long before he was due to apply for parole and be released. There are suspicions that he was murdered to shut him up. But the most important thing of all which happened was that his most important secret research papers were seized by the FBI and 'disappeared'. And that brings us back to Freeman Cope's five articles.

After studying the articles carefully, reading between the lines of what Cope says, and knowing something of how the weird scientific branches of the security agencies operate, it became obvious to me (and it must have been obvious at the time to others) that the FBI had given all of Reich's seized papers to the Office of Naval Research in the 1950s for evaluation and safe-keeping. And that is what brought Freeman Cope to his own discoveries, partly based, as he freely admits, upon Reich's researches. After all, how else would he have known so much about the scientific aspects of Reich's researches, not all of which had ever been made public by Reich?

The Naval agency must have selected Cope, who worked for them, to do some work on Reich's papers because he himself had recently discovered strange forms of energy within the body, by suggesting that superconductivity took place along the double-helix of the DNA molecule and used organic 'Josephson junctions' (named after their discoverer Brian

Josephson, who received the Nobel Prize for Physics for their discovery). These junctions use the weird quantum tunnelling effect, mentioned earlier, in order to control and modify the flow of currents, sometimes in surprising ways; we will return to this subject to discuss them in Chapter 14.

Cope's superiors must have thought him well equipped for having another look at Reich's strange files and papers. I might add that all my attempts to contact former colleagues of Cope to learn more about him have met with total silence, which tells me that these colleagues are bound by secrecy agreements and are terrified to say anything at all.<sup>13</sup>

That is the background. Now for the discoveries.

Cope came to the conclusion that each of us is surrounded by yet another invisible cloud. He describes it as 'a gas of electromagnetic (EH) dipoles.' (A dipole is so called because it has two electromagnetic poles, a north pole and a south pole. A dipole may be a molecule or some other object that has both poles.) He believes this cloud can be detected on rare occasions by sensitive persons, who tend to call it an 'aura'. Cope stresses that he wished to investigate this by sweeping away mystical theories and tackling the matter purely scientifically.

Cope had no knowledge of the microbial clouds that I have described above, and which would not be discovered until thirty-four years after his death. Nor was he knowledgeable about microscopic dust, whether charged or uncharged, and nor was he apparently knowledgeable about plasma either, except in the sense that he may have known about Reich's researches into something that seemed a lot like plasma. That means, of course, that he was also not familiar with the prevalence of dust in plasma, and all the phenomena associated with that. What he discovered was therefore something entirely extra, though the two phenomena may well be intimately related.

He says: '... it is proposed that in the universe around us exist a large number of particles each of which is both an electric and a magnetic dipole.' <sup>14</sup>

Apart from Wilhelm Reich's unexplained findings, Cope's initial stimulus appears to have come from the work over several decades by Alexandre Rothen of the Rockefeller University. Rothen had also been researching a strange phenomenon since 1942; he had been working with

proteins, and he had discovered that molecules could in certain circumstances interact with molecules on the other side of a layer of fat, which should have been completely impenetrable to them. Proteins tend to be spherical, and he started spreading them on the surface of water and discovered that they more or less collapsed and went flat. Normally, by being flattened, they could not have been expected to be capable of interacting with antibodies from the bloodstream.

He laid a layer of beef fat (stearite) across them and proved that it was impermeable to any kind of direct diffusion of molecules across it. But he then noticed that the flattened proteins were interacting with antibodies laid on top of the fat anyway, with which they could have no conceivable form of direct contact. It must be stressed that according to conventional thinking, any form of interaction between these molecules other than direct contact was deemed to be impossible. This was when Rothen discovered mysterious 'action at a distance', previously only observed in the realm of quantum mechanics, operating inside organisms in the everyday realm and having a material effect.

Otherwise known as quantum entanglement, this action at a distance, which Einstein (1879–1955) famously called 'spooky', is the puzzling way that pairs of particles can seem to interact even if they are separated in space – indeed even if they are light years apart.

As result of this astonishing finding, Rothen began an immensely long series of careful experiments, and he was still working to try to solve this mystery in the 1970s. Cope not only drew upon articles published by Rothen between 1971 and 1976, he was also in touch directly with Rothen and received a copy from him of an article that had not yet been published, entitled 'Influence of metallic shields on presumably cosmic radiation ...' Rothen had discovered that there was something else peculiar going on, and it concerned insufficiently understood electric and magnetic phenomena, and some strange form of cosmic radiation, which was also capable of having material effects over large distances.

One needs to recall that Wilhelm Reich had also been concerned with some strange form of cosmic radiation. Cope wondered whether what Reich had looked at and what Rothen was looking at might be the same thing. In going back through even older studies, Cope became intrigued by the meticulously documented and lengthy experiments carried out in the mid-

nineteenth century by Baron Karl von Reichenbach, whose extremely large book *Researches on Magnetism, Electricity, Heat, Light* ... had been translated into English and published as long ago as 1850.<sup>15</sup> Reichenbach's work was at one time fairly well known, but it had been regarded as antique and of little relevance for nearly a century when Cope rediscovered it. He believed it contained much valuable information.

Reichenbach reported that many individuals whom he tested insisted that they could see faint auras around the poles of magnets as well as around people's heads. But Reichenbach was led to formulate a concept of what he called 'odic force', to refer to some unknown energy that was involved. Reichenbach's 'odic force' seemed to Cope to be similar to Reich's 'orgone energy'. Reichenbach did not however discuss the forbidden subject of sex, as sex did not yet exist in 1850, it seems. <sup>16</sup>

Cope also discovered that Rothen was moving on from his discovery of weird quantum effects in proteins to building electronic devices that would duplicate them. He comments on Rothen's experiments, and the type of particles forming the body-clouds suggested by his findings:

Rothen's magnetic electrode experiments seem to require that it [the type of particle suggested by Rothen] be a magnetic particle, which suggests the possibility that it is a magnetic (H) monopole [a particle having a single pole, not two, as with dipoles]. However, H-monopoles have never (with one controversial exception) been observed experimentally despite careful searches ... <sup>17</sup>

Discouraged at the unlikelihood of single-poled 'magnetic monopoles' really existing, Cope fell back on the dipoles that I mentioned a moment ago (any magnetic object will normally have a 'north' and a 'south' pole, which is to say 'di' or two poles) and suggested them instead.

Well, since Cope's day, magnetic monopoles have come back, and as we are about to see, they are fantastically important and wide-ranging in their implications, and so worth taking the time to understand.

The famous Nobel Prize-winning physicist Paul Dirac had predicted the existence of magnetic monopoles in 1931 and published the quantum physics equations that 'showed' it. His arguments are very convincing. In 1948, he published an expanded version of this theory, which has been largely ignored, though it has the potential to revolutionize much of contemporary physics. In this paper he introduces the idea of a 'quantum'

string'. (See my extracts from this brilliant paper and my comments on its radical ideas in the footnote.)

On 30 January 2014, Des McMorrow and Steve Bramwell of the London Centre for Nanotechnology announced their proof of the existence of these monopoles. On 4 September 2015, scientists of the Universitat Autonoma de Barcelona in Spain announced that they had actually produced magnetic monopoles.

Then Georges Lochak, President of the Fondation Louis de Broglie in Paris, and the German physicist Harald Stumpf, a former student of Werner Heisenberg, published a remarkable book in 2015 that revives magnetic monopoles, and contains a veritable tsunami of horribly complex mathematics, a whole book full in fact, to back it up.<sup>20</sup> Indeed, I proofread Georges Lochak's contribution for him to improve the English, as English is only his third language, his first being Russian and his second being French.

Steve Bramwell has stated: 'We have observed monopole currents analogous to electricity.' He also agrees that it should eventually be possible to harness monopole currents for technology, though that is a long way off.

The evidence for the existence of magnetic monopoles keeps piling up, and many physicists are now talking increasingly about magnetic monopole plasmas. This is very important for us, because it means that there may be portions of the Kordylewski Clouds that are plasmas which are not made of charged particles, but instead of magnetic monopoles. In July of 2019, a paper appeared in *Nature* reporting experiments that appear to have confirmed the existence of magnetic monopole plasmas.<sup>21</sup> It referred to numerous other investigators, papers, findings and theories about this subject.

This paper reported the results of investigations with a superconducting device known as a SQUID, to investigate whether the 'noise' that magnetic monopoles would make according to theory really exists. They found it and said: 'Intriguingly ... magnetic monopole flux noise amplified by SQUID is audible to humans.'

They say of their findings that they are 'consistent with other studies that imply that  $Dy_2Ti_2$  and  $HO_2Ti_2O_7$  [Dysprosium dioxide, titanium dioxide: Dy is the rare-earth chemical element Dysprosium that is never found in

nature, but when produced in the lab is known for its high magnetic strength;  $Ti_2$  is titanium dioxide;  $HO_2$  is hydrogen superoxide; and  $O_7$  is an anion of oxygen and in combination means heptoxide] contain a plasma of emergent magnetic monopoles.' And they cite nine references to other papers from *Nature*, the *Physical Review*, and so on.

A 2016 paper they cite discussed both positive and negative magnetic monopoles, which would be the magnetic equivalents of electrons and protons. In other words, there may be a whole other science of plasma taking shape, which verifies the 1979 predictions of Freeman Cope, though he is forgotten.

Let us pause briefly to consider why this is so significant. Scientists expect their theories to be symmetrical and for the most part symmetries are a good sign that your theory may be on the right lines. The established theory of electromagnetism, called the Maxwell-Heaviside Equations (named after the two scientists who formulated them), has a symmetry when it comes to fields – there are both magnetic fields and electric fields. But there is no symmetry when it comes to currents. There are electric currents, but apparently no magnetic currents.

In order to complete the symmetry and for there to be magnetic currents, there would need to be magnetic particles which, like electrons, the particles of electricity, have a charge operating in a single direction. But all magnetized particles known about operate in equal and opposite directions, which is to say they have two poles, one negative and one positive. Therefore, in standard physics there is no such thing as a magnetic monopole.

The quest to discover them has been called the Holy Grail of physics, because not only would this give symmetry to the theory of electromagnetism – with gravity the most important formative factor in the Universe – it would open up a vast new dimension of theoretical physics when it comes to exploring the fields that give our Universe the form it has.

As for the practical implications and how to harness the power of magnetic monopoles; well, that was what Cope was interested in discovering in his top secret work.

In what I will now quote from Cope, we must remember that according to standard scientific symbol protocol, H stands for magnetic and E stands for electric. Also, we must mentally re-insert the monopoles back into Cope's argument, and consider them as well as the dipoles he discusses. Also, Cope uses the polite phrase 'our unknown something' to refer to the strange phenomenon, and he has coined a wonderful phrase, 'magnet auras' to describe the clouds around magnets visible to some people.

Cope says:

... the observation that our unknown something seems to collect near surfaces of magnets (magnet auras) suggests that we may indeed have H-dipoles [remembering that 'H' means magnetic, he means magnetic dipole particles, but we can now add also H-monopoles], which are pulled into regions of high magnetic field gradient; e.g., regions near magnet surfaces.

In other words, since it is known that Cope's 'unknown something' accumulates near magnet surfaces, he reasons that the 'unknown something' must be composed of magnetic particles. He assumes that they would have two poles, north and south. But since his death, magnetic monopoles having been confirmed, we may add that they might just as well have only one pole and hence be monopoles, as he had initially hoped.

He continues, expanding his comments from magnetic (H) particles to electric (E) ones:

Our unknown something seems also to collect near the surface of the human body (human auras). No magnetic field gradients exist there. ('Gradient' in this paragraph refers to a flow of energy either magnetic or electrical.) However, if our H-dipole is also an electric (E) dipole, it would collect also at regions of high electric gradients. The human body forms an electric discontinuity with the electric field around the Earth, thus causing large electric gradients near the body surface. Therefore E-dipoles should collect there.

In other words, since human bodies have electric fields around them, forming 'bubbles' within the normal electric field on the Earth's surface (see a drawing of a human standing in such an electric field bubble in Chapter 17, Figure 32, <a href="here">here</a>), Cope's particles would collect there.

Cope goes on to explain how these new insights mean that Wilhelm Reich's supposedly crazy 'orgone accumulators' might really have worked. After explaining how a sandwich of dissimilar materials arranged in a certain way – perhaps not unlike the layers in Rothen's original experiments – might be able to trap such particles, he makes this explicit statement:

Because of this effect, a box made of two layers of dissimilar materials might accumulate and concentrate EH-dipoles from a surrounding gas of EH-dipoles, analogous to the experimental

## He adds:

Reich seemed to observe accumulation of some sort of solar radiation [remember I said earlier that Reich believed his orgone energy was being streamed from the Sun to the Earth] with physiological activity within bilayer boxes (sheet iron covered by cellulose) ... we may expect bilayer structures to act as diodes or rectifiers (both are devices that conduct a current in one direction) for EH-dipoles. A box constructed from such bilayer sheets might therefore operate as an EH-dipole accumulator, which would explain some of the phenomena observed by Reich. <sup>23</sup>

This is an astonishing revelation. Reich was sent to prison for making orgone accumulator boxes of exactly this kind, which he insisted were trapping some unknown solar energy that he named 'orgone'. Here we have Cope, twenty-three years after Reich's death, and obviously entrusted by the American security establishment with evaluating Reich's research papers, concluding that Reich's orgone accumulators probably worked after all, and paving the way for these to be understood in terms of magnetic monopoles that have since been shown to exist. Cope is talking about reconstructing the very same boxes that were chopped to pieces with axes in front of Reich's eyes by FBI men outside his house, and their constituent parts thrown onto a fire with his books.

It is beginning to look as if Wilhelm Reich may have been a twentieth-century Giordano Bruno. What kind of mad frenzy possessed the FBI men to behave like this? As I've already mentioned, Reich's books had previously been burned by Himmler's SS and then they were burned again by fanatical opponents of his scientific findings within the American Government.

At this point in his account, Cope begins to refer to the work of another brilliant scientist who seriously challenged orthodoxy, Herbert Charles Corben. In his 'day job', Corben was one of the world's leading experts on spinning particles, who wrote the definitive book on the subject for that time in 1968, which is so heavily mathematical that you need swamp boots to wade through it.<sup>24</sup> But when left free for his thoughts to roam, Corben was an astonishingly bold thinker, as we see in a rather visionary article that was published in 1978, from which Cope draws.<sup>25</sup> Cope and Corben were also in personal touch and exchanged information privately, as Cope makes clear.

Anyone who thinks that monopoles and 'orgone' energies are 'way out' phenomena will perhaps be surprised to hear that the subject of tachyons is even more so. And Corben seriously investigated tachyons, along with a small number of like-minded scientists. What are tachyons? They are particles that travel faster than the speed of light – and they are predicted by relativity theory. 'What?' you may exclaim. 'But surely it is relativity theory that says that nothing can go faster than the speed of light?' Well, not really ... But if we get into the speed of light, then this book will become twice as long, and we cannot allow that to happen.

A tachyon, like the magnetic monopole, is a particle that exists in theory, but is in practice a very rare bird, which most scientists would probably say does not exist in the real world. Before we get too sceptical, we should remember the way physics evolves. It often happens, and happened in the case of the Higgs boson, for example, that a particle is shown to exist in theory many years before it is actually verified by experiment.

So I will have to ask you to swallow hard and try to take my word for it, that tachyons may turn out, as magnetic monopoles have now done, to exist after all, despite a chorus of doubters shouting 'crazy!' The moral to this story is: When someone shouts 'crazy' at you, put your fingers in your ears and carry on.

Drawing upon discussions with Corben, Cope was able to expand his theory of clouds of dipoles surrounding the human body and suggest that clouds of EH-monopoles might actually be tachyons. This would mean that even the laziest person on earth, the teenager who sleeps all day for instance, may at all times be surrounded by a cloud of particles going faster than the speed of light. So when an exasperated mother shouts at her teenage son, 'Get out of bed, it's the middle of the afternoon!', he might justifiably call back to her, 'I'm completely exhausted because my body-cloud has been going faster than light all night long.'

Without going into all the technical details, fascinating as they are, I shall give some of the conclusions that Cope comes to on the basis of all of this. He and Corben worked out together that diffraction patterns [interference patterns of waves that can tell you the frequencies of the waves] of tachyons could create 'certain resonance interactions or standing wave patterns of interactions between the tachyons and crystals'. <sup>26</sup> (Remember what I said

earlier about solitons and standing waves? To explain resonance interactions, which can create standing waves, would require too lengthy an account. But when wishing to understand resonance, think of music, and harmonious chords as opposed to those that are not. The most harmonious chords are called fifths by musicians, and are examples of harmonious resonance.)

Cope is saying here that if tachyons do exist, their rhythmic interactions would naturally make them resonate with crystalline structures in intimate and interesting ways. This is a wonderful vision and a joy to conceptualize. Critics may say it is highly speculative, but Cope found a way to describe the relationship between crystals and mysterious energies in scientific terms. He found a scientific language for it.

Cope goes further. He comes up with mechanisms in the form of 'superconductive regions' to explain how these particles might be the trapped within the body. (Again, superconductivity is when electricity travels without resistance.) He also suggests that on the planetary scale, these phenomena could create a standing energy grid, a vast grid system of resonant standing waves of 'earth energy'.

He adds as a footnote that this could explain dowsing, if we all have these particles inside us rendering some people hypersensitive to invisible energy fields. In relation to dowsing, returning to the subject of magnetic monopoles, Cope says:

My hypothesis is that the long sought magnetic monopoles are all around us, and are in the form of delocalized tachyon (faster-than-light particles) clouds, which form periodic wave functions detectable by sensitive quantum mechanical processes in man ... the general pattern of reported experimental observations seems to suggest that delocalized clouds (wave-functions) of tachyon magnetoelectric monopole polymers (substances made up of large molecules) surround all solid and liquid objects, and that these ... are detectable by sensitive persons trained in dowsing techniques. The detection is presumably by quantum mechanical interactions with living cells ... Dirac monopoles exist as large, delocalized, polymeric clouds (or wave-functions) with spatial periodicities ... 27

I realize that this is very technical language and probably confusing. But what he is saying is that there are these clouds surrounding each and every one of us, and indeed not just us but 'all liquid and solid objects'. Thus, we are all surrounded not only by charged dust and microbes, but by even smaller electromagnetic particles, which are whizzing round us constantly

faster than the speed of light and causing effects that we have not yet even begun to explore or explain.

And in this connection, I should add that bees and flowers also have an electromagnetic dimension. For scientists at the University of Bristol have proved that bees when flying around are positively charged, and sense the flowers that are negatively charged, using specially sensitive small hairs on their faces. The pollen that they gather also becomes charged, and then the charged dust is scattered in the air by the bees rustling around inside the flowers. We may thus look upon bees and flowers as engaged in a continuous orgy of charged intercourse with one another, generating and displaying their auras and creating plenty of charged dust in miniature clouds as they do so.

It really is true to say we live in an electromagnetic world, and are only beginning to understand how it works. All of us are electric people, full of multiple currents of both negative charge, called electricity, and positive charge, called proticity. Since charged currents always generate magnetic fields, we are also all full of multiple magnetic fields. When we say that people sometimes have 'magnetic personalities', we may be closer to the truth than we thought.

## Electric People

I have known many distinguished scientists over several decades and had opportunities to sit around discussing these issues with many of them, often for hours, and sometimes for days. The first scientific Nobel laureate I met, aged eighteen, was Paul Dirac (1902–1984), who won the Nobel Prize for Physics as long ago as 1933. I went to tea with him in his rooms at Cambridge and spent four hours with him. He was a great admirer of tea time and made quite a fuss of it, pouring tea and serving dainty little sandwiches, small tarts and cakes.

Dirac was very solitary and silent and rarely talked to people. I seem always to have had a way of getting such people to chat; in Dirac's case, I instinctively knew that I must sit in my chair at a 60-degree angle from him so that he could talk 'without being observed'. He had in fact put the chair there and I knew that its angle was the key to having a conversation with him, as he could not talk to people comfortably if they were looking directly at him face on.

Dirac shyly confessed to me that he was far more interested in biology than he was in physics, but he said he did not dare to tell anybody that in Cambridge. Dirac did not accept physics as it was at that time. He complained that no one would listen to him about quaternions (a number system that he believed essential for understanding quantum mechanics, but which his contemporaries insisted had no practical applications), and he thought physics was in many ways on the wrong track. This had a big impact on me, for there I was in conversation with a living legend of science, and he criticized the very foundations of the science of his time and even preferred a different scientific discipline from his own because it was more lively.

That was an early encouragement to my own scepticism about anything and everything that 'everybody believes'. I have an inclination to think that 'everybody' is always wrong. We discovered that we had both entered university at the age of sixteen, and we talked about that and how it teaches one to be a bit isolated from one's contemporaries, because they are not really contemporaries chronologically at all, but already well on the way towards becoming ossified and rigid. I have written a long account of that interesting meeting, which perhaps I shall publish one day.

Dirac was one of the few scientists who have had the courage to speak of these uncertainties openly – like my hero Percy W. Bridgman did in his books. Bridgman had won his Nobel Prize in 1946, he had been a famous Harvard professor for decades, and he did not give a damn if querulous and timid colleagues decided to turn on him, savage him, and call him crazy because he was pointing out that not only one emperor, but many wore no clothes. Bridgman was that most honest of persons: someone who is not afraid to admit that he does not know things. He admitted that he did not know what 'a field' actually was, but he went further and said that no one did.

My old friend David Bohm is well known for formulating his alternative interpretation of quantum mechanics, which involves something that he called 'the quantum potential'. When I asked him what the quantum potential actually was, he said he did not know, and that no one really knew what any of the potentials in science were. He had come up with the ideas mathematically and hoped one day to find out what it was, but meanwhile it was just there in the equations and he could describe what it did, but not explain what it was.

It is heartening to know that there are some famous physicists who have courage. But if you have courage in life you will suffer, because the herd will attack you. Most of my scientist friends or good acquaintances, many of them very famous indeed, have been at heart renegades. What does it mean to be a renegade? It means that you use your own brain rather than the herd's brain.

I befriended David Bohm in 1982 when he was Professor of Theoretical Physics at Birkbeck College London. The reason I mention David at this point is because I want to quote from my own article. These are words of his that come from the voluminous sound tapes which I made with him over the course of many meetings:

What is an electric field? We don't know. If we knew, we would know why field and charge are connected in the particular way in which they are ... when I was a child people would say 'Electricity is very mysterious.' Now we say it's not so mysterious, but still nobody knows what electric force really is. We're used to it, that's all, by giving it a name and getting used to handling it ... What is a gravitational potential, what is an electrical potential, what is a quantum potential? You see, you would have to explain all the forces and explain why they act on particles. Now, nobody has done that. \frac{1}{2}

The non-scientist may be astounded to hear this confession from one of the most famous physicists of the twentieth century, but many of the most brilliant scientists have expressed these and similar sentiments not only in private, but in many articles and books. One example was my close friend, Peter Mitchell, of proticity and the protic motor (here), who insisted to me many times that 'nobody knows what energy really is'. And the famous physicist Richard Feynman (1918–1988) was honest about our ignorance. He bluntly said, 'I think I can safely say that nobody understands quantum mechanics ...'<sup>2</sup>

And elsewhere he made statements such as these:

Whether the proton decays or not is not known. To prove that it does not decay is very difficult  $\dots$  there are  $\dots$  quantum theories of gravity  $\dots$  (but)  $\dots$  there is no way to test them  $\dots$  The best of these theories is not able to include the particles that we do find, and invents a lot of particles that we don't find  $\dots$  there remains one especially unsatisfactory feature: the observed masses of the particles, m. There is no theory that adequately explains these numbers. We use the numbers in all our theories, but we don't understand them – what they are, or where they come from.<sup>3</sup>

Nobel laureate Ilya Prigogine, whose work was discussed in Chapter 3, said:

I think we are only at the beginning of science. We are at the beginning of studying the complexity of Nature. The classical universe was a simple, quiet universe. And now we see, we only conceive the extraordinary complexity of nature, like for example the complexity of the gene expression. We still don't understand completely the structure of the gene. Yet I don't think that once we understand the structure of the gene we shall see the meaning of man, because the genetic content of a mouse and a man are very similar. Therefore the non-genetic part of biology is very important. But we know little about it ... In addition I would say there is no fundamental science ... why do we have so many elementary particles? Nobody knows ... we still don't know the origin of the Universe. The theory of the Big Bang is the most widely accepted theory, but what is the Big Bang? ... We are at the beginning. I always say that we are at the beginning of a new science, not at the end of science.<sup>4</sup>

So now we come to another remarkable man and great scientist, Albert Szent-Györgyi (1893–1986), who became a great influence on many pioneers in this field, and with his contemporaries Alfvén, Bostick, Kapitsa and Cope, one of the great heroes of the history of plasma. He was a Hungarian whose surname means Saint George and is pronounced just like 'Saint Georgie'. He was the second scientific Nobel laureate whom I met, when I was twenty-one. He won the Nobel Prize for Physiology and Medicine in 1937 when he was still Professor of Medical and Organic Chemistry at the University of Szeged in Hungary.

By the time I met him, he was an exile living in America, whither he had fled in 1947 from the Communist regime of his native country, and he was working at the Marine Biology Lab of the Woods Hole Institute on the coast of Massachusetts, where I visited him for an afternoon.

Things had not gone happily for him in Hungary during the Second World War because of the Nazis. He had led a resistance movement against them and saved many Jews from being killed, and was lucky not to have been captured, tortured and killed by the Gestapo himself. The Hungarian Prime Minister sent him to Cairo to negotiate secretly with the Allies, and Hitler personally issued a warrant for his arrest. Szent-Györgyi was a larger-than-life extrovert character, with a ravaged face, a good sense of both humour and sarcasm, and someone who was not shy when it came to letting his genius glitter in conversation.

What is important for our story is that it was Szent-Györgyi who laid the true scientific foundations for the electric view of humans (and of all plants and animals also, for that matter). It is not for nothing that his most famous and provocative books are *Bioenergetics* (1957) and *Bioelectronics* (1968). I met with him in the summer of 1966, before the latter book was published. In 1976, he carried his views further and published *Electronic Biology and Cancer*. He believed that cancer was a condition associated with electrical and electronic malfunctions within the body.

Szent-Györgyi's *Bioenergetics* is such an amazingly provocative, challenging and brilliant book that its full effect has not been felt even today, for it contains insights that have yet to be pursued. It is a bombshell still going off, even though it appeared three-quarters of a century ago. I don't imagine any physicist read it at the time, because it is so heavily technical about biochemistry that few if any physicists could have

understood most of it. It was published before the discipline now called biophysics came into being. In fact, it was Szent-Györgyi who helped to provide the impetus for the founding of the science of biophysics, by injecting discussions of physics into biochemistry to such an extent that biochemists were forced to learn some physics in order to comprehend what he was telling them.

Indeed, Szent-Györgyi in his 1976 book *Electronic Biology and Cancer* based a portion of his arguments upon the work done by the famous French physicist Léon Brillouin (1889–1969), thereby forcing any of his colleagues who wished to understand him to study Brillouin's unique discoveries about electrons and the energy levels named 'Brillouin Zones' after him.<sup>5</sup> Brillouin had been insisting that semiconductors existed inside the body. Also, Szent-Györgyi had referred to Percy Bridgman's seminal book *The Physics of High Pressure* (1949), forcing his colleagues to read Bridgman in order to understand one of Szent-Györgyi's most important ideas.

For more than twenty years, Szent-Györgyi had been relentlessly pushing physics into biology, and it was becoming impossible to ignore this, so that the discipline of biophysics had to be born to cope with it.

He remarked in his 1957 book *Bioenergetics*:

Experimental evidence for the existence of a semiconductor [semiconductors are necessary for the ordered flow of electricity] nature of biological material is not missing ... chloroplasts [the tiny organelles inside plants that carry out the process of photosynthesis] can 'store light', that is, conserve the energy of absorbed photons, which energy they could again shoot out later in the form of light, if heated ... That energy can move through protein molecules is an experimental fact ... I have no doubts that the coming century will witness a profound revolution, extension of biology, the establishment of a quantum mechanical biochemistry ...

This book may be but one of the early swallows of this spring.<sup>6</sup>

We will see later that the quantum mechanical qualities of plasma, some of which we have already touched on, are crucial for understanding its role in the evolution of high levels of intelligence.

*Bioenergetics* was indeed an early swallow, and an influential one. It may have gone unread by many people, but they knew it was there, lurking. It is immediately obvious, if one thinks about it, that Albert Szent-Györgyi was an outstanding genius who was denied proper recognition in the United States; he discovered Vitamin C and won the Nobel Prize, but was he ever offered a professorship in America? No! Was he ever head-hunted by one of

the Ivy League universities? No! Did the Institute of Advanced Studies at Princeton ever try to recruit him? No! Was he ever awarded any of the usual distinctions? No!

Instead, he took refuge in an oceanographic institute, which is what Woods Hole is. And he was given a job in a Marine Biological Laboratory. What on earth did Szent-Györgyi have to do with fish? Pretty much nothing. In fact, he was relegated eventually to something called the Institute for Muscle Research. It is true that he had done a lot of research on muscle and was one of the world's experts on the subject. But for him, that was a sideline. What was really going on was that the American scientific establishment was clearly afraid of Szent-Györgyi, wished to exclude him from the mainstream, and tried to prevent him upsetting all of their empty apple carts. And the appearance of *Bioenergetics*, throwing a bomb into the middle of all of conventional biological thinking, did nothing to render him less dangerous to the mediocre minds of the establishment figures.

With his book *Bioelectronics* (1968), Szent-Györgyi became even more of a threat to standard thinking. The first two sentences in his book are:

The greatest stride in biology, in our century, was its shift to the molecular dimension. The next will be its shift towards the submolecular, electronic dimension. <sup>7</sup>

He went on to speak of plasma existing in every molecule in the body, saying each molecule contains something that 'can be looked upon as an electron gas pervading the whole molecule'. An electron gas is a negatively charged plasma [negatively charged because electrons always have a negative charge, being distinct from the ionized, positively charged plasmas we have, for the most part, been discussing]. Publishing something like this, insisting that there was a branch of biology that was electronic, that every cell in the body was electronic, and that every molecule contained plasma, was too much for the scientific establishment. Most biologists did not have the faintest idea how electronics worked even in a radio, much less in a molecule.

The more Szent-Györgyi published things that required people to stretch their minds, asking biologists to learn a little bit about physics and a little bit about electronics, the more certain it became that he would never be accepted or recognized in America. He could not go back to Hungary, because he would probably have been arrested, tortured and shot. He was also not in favour with the American security establishment, because he had led an anti-Nazi movement, whereas America in the 1950s and 1960s was being flooded with ex-Nazi scientists being brought over by Allen Dulles of the CIA as part of Operation Paperclip and other such projects.

But worst of all for Szent-Györgyi was the fact that Hitler's personal hypnotist, Ferenc Völgyesi, who had carried out hypnotic experiments on more than 60,000 Jews and Gypsies in the death camps, had become Allen Dulles's little darling, given a new identity as 'Frank', treated as an American, and put in charge of all the American security establishment's mind-control operations. And he was Hungarian.

Völgyesi was clearly going to use his influence with Dulles to prevent a distinguished anti-Nazi Hungarian from gaining any recognition at all in America, lest Szent-Györgyi might spill the beans on Völgyesi being a war criminal and a fanatical Nazi responsible for the abuse, torture, and deaths of thousands of Jews. And the CIA must have gone into full gear to keep Szent-Györgyi as obscure as possible, hidden away in his little port on the Massachusetts coast and buried in harmless muscle research, given no attention, and having no opportunity to acquire an audience who might ever listen to him.

Szent-Györgyi was in any case handicapped by terrible personal grief, because both his wife and his daughter had died of cancer by 1972, when he dedicated his book *The Living State: With Observations on Cancer* to their memory, saying in his Introduction that cancer 'took away most of what was dear to me'. And in his Preface, he thanked those few people who had 'helped to keep me "above water". <sup>9</sup>

A brief but fascinating account of a conversation with Szent-Györgyi has been published in Andrew Marino's autobiography. They met in San Francisco in June of 1980 (Szent-Györgyi died in 1986). Szent-Györgyi complained bitterly to Marino that he had never been able to get any federal grants for his research during his years in America, confirming my suspicion that he was blacklisted by the security agencies to make sure he never received any support for anything at all.<sup>10</sup>

Despite all this, Albert Szent-Györgyi laid the groundwork for crucial discoveries and developments in science, by helping to create the discipline

of biophysics and introducing so many new and exciting notions that are still being explored today. For instance, he is looked upon as the 'grandfather of biophoton research', a subject I will be discussing in Chapter 15. He describes how 'ultra-weak' photons are emitted by the body; which, when their emission is correctly detected, has enormous implications for the early detection of diseases, especially cancer.

He also laid the groundwork for much of Peter Mitchell's work, turning upside down the discipline of bioenergetics and the explanation of how energy is used within the human body, and explaining how energy is transported across membranes and used in cells. But the main point of all this for us here is that the details of what Szent-Györgyi says in his books relate directly to the nature, structure and workings of intelligent plasma entities.

In *Bioenergetics*, Szent-Györgyi refers to the fact there are several different kinds of ice. This may surprise many people! Surely ice is ice, isn't it? Well, no, not really. Szent-Györgyi found this information briefly referred to in Percy Bridgman's *The Physics of High Pressure* (1949). <sup>11</sup> Bridgman was possibly the world's leading investigator of high-pressure phenomena, and he refers to 'the high-pressure modification of ice'. With the correct pressure techniques, one could change one form of ice into another. He could change Ice I into Ice III, Ice V, and Ice VI, for instance. All these are ices made of pure water, but they are different water ices.

Research into different ices continues today. In 1998, the number of different kinds of ice increased to twelve, as Lobban, Finney and Kuhs published in *Nature* an account of their discovery of Ice XII. <sup>12</sup> But by 2016, the number of ices had grown to eighteen. Although these different ices are described as 'crystalline phases of ice', they vary a great deal. Their oxygen atoms tend to remain in fixed positions relative to each other, but their hydrogen atoms do not. In addition to the eighteen crystalline ices, there are three non-crystalline ices known as amorphous ices. So that makes twenty-one kinds of ice so far, all of them made solely from water.

There is also 'hair ice', which exists as thin threads spreading between trees, and 'ice flowers', which are produced by some plants but not others. No one knows why.

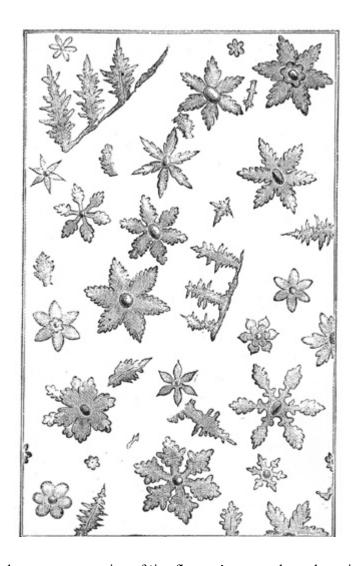

Figure 28, A nineteenth-century engraving of 'ice flowers' as seen through a microscope.

Does this mean there are twenty-three kinds of ice? Are there more? What does it mean to have twenty-one kinds of ice? Or twenty-three? Or fewer? Or, frankly, even only two? Are the different ices also different kinds of matter? Or is ice just ice, regardless of which of the eighteen or twenty-one or twenty-three kinds it is?

Crucially it is not only ice that behaves in various strange ways. In *Bioenergetics*, Szent-Györgyi may have caused the greatest upset to his colleagues of all by discussing the weird nature of water. These days there are many books, many of them New Age titles, discussing different kinds of water at great length; they concern such ideas as 'water having memory', to explain how homeopathy is possible (where the dilution of a drug in water is so extreme that not one molecule remains, and yet the water appears to

retain a potency derived from that drug anyway), and many other mind-boggling ideas. But Szent-Györgyi's thoughts on the strangeness of water in 1957 are so extraordinary that I must quote a bit of what he says:

When considering water structures we enter a fantastic and fascinating world. Bridgman, in his studies on high pressure, could distinguish between half a score [ten] of different ices. But we need not go to ice to find structures in water. [J.D.] Bernal and [R.H.] Fowler ... showed water to have a quartz-like 'crystalline' structure which is different from that of common ice ... The situation becomes more complex still if we consider water structures built around solid surfaces. The tendency of building structure-ordered layers around surfaces running deep into the fluid phase seems to be a general tendency of liquids ...

The surface zones of liquids are tens and hundreds of molecules deep, rather than monomolecular, as commonly assumed ... water ... around ice (behaves) not as water but as 'liquid ice' ... These layers of ice were found to be several microns deep ... the building of lattices means 'long range order' in which the single molecules collaborate collectively ... No attempts have been made yet to apply our knowledge of water structures to living systems ... Living matter seems to be a system of water and organic matter, which forms one single inseparable unit, a system, as the cogwheels do in a watch.

Water is not only the mater, mother, it is also the matrix of life on Earth, and biology may have been unsuccessful in understanding the most basic functions because it focused its attention only on the particulate matter, separating it from its two matrices, water and the electromagnetic field. <sup>13</sup>

What is most interesting of all in this for our purposes is that Szent-Györgyi grasped the importance of 'structured-ordered layers around surfaces' within a watery mass (in other words the concept of a mass of water containing protected, or walled, cells within itself, which themselves are made entirely of water). These boundary layers within water are analogous to the boundary layers known as sheaths found within plasmas. All plasmoids are enclosed by sheaths. That is how they maintain their identities.

Szent-Györgyi had a deep intuition of the extraordinarily complex, dynamic structures that inform naturally occurring materials, including ice, water and plasma, but of which science had been ignorant before his discoveries. We have been building complex plasma entities having countless plasmoid regions within them, all protected within their sheaths.

Researchers such as Kapitsa, Bostick and Tsytovich have shown that some of the plasmoids contain hot plasmas, some cold plasmas, some dusty plasmas, some non-dusty voids, some containing specific impurities that hinder or accentuate the flows of charged currents precisely in the manner of electronic semi-conductors and transistors. Furthermore, there is the

mysterious phenomenon called 'tunnelling' (to be explained in a moment) that takes place between them, and there are also superconducting and superfluid portions and sections. That water and plasma – which Szent-Györgyi showed to be present throughout human bodies – spontaneously generate structures adds a whole new dimension to the argument.

In order to understand the implications of Szent-Györgyi's work in more depth and to see how it works in practice, we will look again at superconductivity and Josephson Junctions, before delving back into the weird and shadowy world of Freeman Cope.

## Superconductivity and Josephson Junctions in the lab, outer space and human beings

It often happens in the history of science that a new scientific theory will give rise to new inventions. This is quite natural, but sometimes it happens the other way round.

The invention by Brian Josephson of Josephson Junctions as a device to control and regulate electric currents in complex machines helped drive the development of machine intelligence and eventually quantum computers. This in turn gave rise to theories that there might be things in nature that have similar functions.

We have already touched on the idea that there might be features in complex dusty plasmas in space which have similar capabilities to computers, and that these may help the evolution of intelligence in space. Now we are going to look at features that resemble Josephson Junctions in plasma in human bodies. We will do this before we actually explain Josephson Junctions.

The story starts in 1911 with the observation of superconductivity in a lab by the Dutch scientist Heike Kamerlingh Onnes. When electricity flows along a wire, it is called electrical conduction. When it flows through something without any resistance at all (an amazing phenomenon that scientists could barely believe when it was first discovered), it is called superconductivity.

Superconductivity is entirely counterintuitive. Everything that has traditionally been known about electricity is that it encounters resistance as

it flows along, and as everyone who has ever had anything to do with electronics knows, and every electrician who wires your house, the units of resistance are known as 'ohms', named after the German scientist Georg Ohm (1789–1854).

At first, superconductivity was thought to take place only at extremely low temperatures near Absolute Zero, temperatures so low that in everyday life we never encounter them, because they have to be artificially created by scientists and technicians. But then as time went on, it was discovered that superconductivity could take place at higher and higher temperatures, and it was discovered that current could flow in this manner through increasing numbers of materials, many of them artificial.

### As Freeman Cope put it:

Superconduction is the passage of electron current without generation of heat and hence with zero electrical resistance. Such behavior has been observed only in inorganic materials and only at temperatures below approximately 20°K [on the Kelvin scale; it equals minus 253.15 degrees Celsius], although theory predicts that superconduction might occur in organic materials at room temperatures. <sup>14</sup>

When current is flowing by superconductivity, it encounters no resistance at all; it can go on forever. It is, in fact, an electric version of a perpetual motion machine. If flowing in a coil under suitable circumstances, the current goes round and round by itself with no power source and it can in principle do this for eternity. It needs no recharging. It flows like an endless river. In fact, machines creating superconductivity have been made, which – all other things being equal – will continue to flow beyond the end of the Universe, if the Universe should actually end, that is (which in my opinion it will not).

The next great breakthrough for our purposes came in 1962, when Cambridge physicist Brian Josephson predicted with mathematical precision how a supercurrent would leap over a thin insulating barrier connecting two superconductors by means of the quantum phenomenon called 'quantum tunnelling'.

This precision is key. Josephson realized that by modulating the insulating barrier between the two superconductors, the flow of current could be modified. If electricity flows too strongly and too well, it is too powerful for electronic devices and can overwhelm them. And if it cannot

flow at all (through an insulator), it is obviously of no use whatever. Because of what became known as Josephson Junctions, it became possible to use superconducting electricity that was not too strong, but of semi-strength only, and by varying the semiconductor materials by adding small amounts of this or that substance (what is called 'doping'), the strength of the electric flow could be varied and fine-tuned.

These junctions are what make our most advanced modern computers possible, and without semiconductors (the ordinary ones, which had been known for a long time before this and that regulate normal electrical flow very precisely) there would be none of our contemporary electronic devices. There would be no portable computers, no cell phones, no tablets, and hence no internet, and so on.

Josephson was awarded the Nobel Prize for Physics in 1973 for his discoveries. He is another one of the Nobel laureates whom I have met and talked with about their work. He is a very shy and modest fellow, whose success in science came to him so young that he was rather intimidated by it all and for a long time seemed to dread all the attention he received. One day I must transcribe the tapes I made of our conversation.

Josephson Junctions are also fundamental to the development of a quantum computer. Indeed, some scientists go so far as to speak of a 'Josephson Quantum Computer'. Josephson Junctions can now be made at the nano scale, with a thickness of only one tenth of a nanometre. They are able to act as computer switches so sensitive that they control currents one electron at a time, letting an electron through when desired and blocking an electron when necessary. This level of control has already been perfected, and when quantum computers finally come onstream, it will probably be because of the pioneering work and insight of Brian Josephson. For radiation detection purposes, vast arrays of tens of thousands of tiny Josephson Junctions working in synch are capable of obtaining results unobtainable by any other known means.

In a dusty complex plasma that has developed emergent properties of self-organization, where superfluidity is made possible by countless layers of sheaths, cells and crystals, we can expect superconduction and Josephson Junctions to form the basis of the energy flows within the plasmas. A dusty complex plasma such as a Kordylewski Cloud would thus be expected to have more than a trillion trillion trillion Josephson Junctions within it. (Or

just keep adding the zeroes, as they would in effect become incalculable in number.)

Intelligent calculations by such conscious plasmas would be so rapid and so massive that a Kordylewski Cloud would easily have the capacity to monitor every living creature on Earth in real time and model future events for all of them. Such a cloud could thus foresee with a high degree of probability what would happen in almost any Earth situation, and have models of every conceivable variable's effect on events. From the point of view of the limited human brain, a Kordylewski Cloud therefore has the capacity of what to us would be indistinguishable from omniscience.

If this complexity is possible in plasmas in space, what about in the human body? We know from Szent-Györgyi's work that the human body contains organic semiconductors. For the achievement of the Josephson Effect within our bodies, these can suffice for the necessary 'barriers' to create the 'jump'. The impetus for the 'jump' can come from something called 'the Proximity Effect'. When two superconducting currents are near enough to each other, they can influence each other because of their proximity, and this can result in a Josephson Effect if there is an organic semiconductor available.

To understand the implications of Szent-Györgyi's discovery in more depth, we need to dive back into the weird world of Freeman Cope. I originally discovered his publications in the mid-1970s, as at that time I was constantly in Oxford doing research, though not living or based in Oxford. I would drive down to Oxford from the cottage where I was living in our little Morris 1000, which had an engine like that of a lawnmower, cold wind whistling in through the soft roof, and a heater so feeble that to avoid freezing in the winter one had to wear a heavy overcoat covering one's legs.

The irony is that I was studying organic superconductivity, which generates no heat because it encounters no resistance. So it would have been of no use when driving.

The journal I had discovered was *Physiological Chemistry and Physics*, published by the Pacific Publishing Company in Portland, Oregon, which is where they were at that time (they are now in Melville, New York). This exciting journal was packed full of astonishing articles and they were causing me to look at the physical body in an entirely new light.

As I looked into this more deeply, I discovered that William A. Little of Stanford University seems to have been the first person to start this chain of reasoning going. As early as the summer of 1964, he had published a paper in the prestigious *Physical Review* entitled 'Possibility of Synthesizing an Organic Superonductor'. He concluded that 'superconductivity should occur even at temperatures well above room temperature' using 'certain organic polymers (substances made up of large molecules with repeating subunits) ... which could have considerable biological significance.' After surveying numerous technical issues, he said: 'This forces upon us the remarkable conclusion that superconductivity could and should occur in structures such as this even at room temperatures.'

These findings tied in with work Cope had been doing since 1963, and he cites in footnotes relevant publications of 1963, 1964, 1970, and 1971, when he published his first major paper making claims of superconductivity in the body, in the 1971 article I cited a moment ago. In this paper, Cope refers to 'electron tunneling', which is the essence of Josephson Junctions.

Cope says in his paper:

we may predict ... special characteristics that superconductive biological systems should have, for which pertinent experimental data already exist. First, cells which perform single electron superconductive tunneling might also perform two electron (Josephson) superconductive tunneling [relating to] nerve processes ... The apparent association of superconduction with growth which is indicated by the evidence of this paper.

The importance of the distinction between single and two electron tunnelling is that the latter are of a higher order when it comes to controlling the flow of currents, and they come into play when Josephson Junctions are used to control superconducting currents. A Josephson Junction, to put it simply, can act as a switch.

The following year, in the same journal, two Hungarian scientists published a paper commenting on Cope's ideas, and concluded:

The  $\dots$  electron tunneling between the mentioned regions of DNA might be responsible for the experimental facts described by Cope, if we accept his hypothesis about superconductive tunneling in biological systems.  $^{16}$ 

In the spring of 1973, Cope published another paper in the same journal carrying his ideas further.<sup>17</sup> In this paper, Cope said:

Various species of organisms can detect weak magnetic fields (0.1 to 5 Gauss) [Gauss units are a measurement of the field strength]. Indirect evidence suggests that electron tunneling may occur across junctions between superconductive micro-regions in living systems. Man-made superconductive Josephson junctions have been fabricated with magnetic sensitivity as high as 10–11 Gauss. It is suggested that superconductive Josephson junctions in living systems may provide a physical mechanism with more than enough sensitivity to explain the observed responses of organisms to weak magnetic fields.

Considering what was said about Cope in Chapter 13, it is interesting to note that at the end of this paper Cope states that his work was 'supported in part by Office of Naval Research Contract NR 105-717.' Cope had obviously persuaded his military security agency bosses that what he was doing deserved funding. A month later, the same journal received a paper from J.P. Marton extending Cope's ideas to considerations of cancer, and this appeared in the next issue of the journal. Entitled 'Conjectures on Superconductivity and Cancer', the paper by Marton said:

On the assumption that biological cell membranes possess superconductive properties and that dead and cancerous cells do not ... the mechanism of control for embryonic, normal, and cancerous tissue growth may be explained. <sup>18</sup>

The next spring, in the same journal, Solomon Goldfein (1914–2003) one of the brightest scientists working for the US Army's Engineer, Research and Developments Labs in Fort Belvoir, Virginia, contributed to the discussion. Perhaps the Army did not wish to be left behind by the Navy! Goldfein's paper was entitled 'Some Evidence for High-Temperature Superconduction in Cholates' and started his paper by saying:

When [William A.] Little examined [Fritz Wolfgang] London's idea [of 1937] that superconductivity might occur in organic macromolecules ... he concluded that it was not only possible but might even occur at room temperature. 19

By summer, once again in the same journal, Cope published yet another paper in which he said:

Superconduction is the passage of electron current without generation of heat and hence with zero electrical resistance, accompanied by particular kinds of interactions with magnetic fields. Until recently, such behavior had been observed only in certain metals, and only at temperatures below approximately 20°K. Theorists have long predicted, however, that superconduction might occur in organic solids, which theoretically might superconduct even at room temperatures and above.

Cope was also reporting evidence that some functions of nerves are controlled by superconduction and he proposed that biological sensitivity to weak magnetic fields is comprehensible only in terms of a biological superconductive Josephson Junction. Once again, Cope acknowledges the Office of Naval Research and Contract no. 105-717.

Also in early 1974, Profesor Antoni K. Antonowicz of Poland published an article entitled 'Possible Superconductivity at Room Temperature' in *Nature*.<sup>20</sup> This attracted wider attention and was reported in the *New Scientist* magazine on 28 February 1974, p. 525, beside a report on work by Freeman Cope. Antonowicz was reported as using a sandwich of amorphous (which is to say non-crystalline) carbon between aluminium films to engineer Josephson junctions, and he like Cope discovered that the tunnelling involved was modulated by a magnetic field.

Cope next delivered a paper to a conference in 1978, the abstract only of which was published in the volume of conference Proceedings by the US Department of Energy. He discussed how superconductive Josephson Junctions make it possible for organisms to detect not only weak magnetic fields but also microwaves, and he referred approvingly to the work of Antonowicz.<sup>21</sup> Cope's full paper appears never to have been released for publication.

At this point, Cope's involvement in this subject appears to have ended, and in this same year he switched his work to the dipole clouds that have already been discussed.

No one else has ever done a survey of these publications, and I thought it necessary to put it all on record, as it was an important episode in the history of science. Since this flurry of exciting papers appeared, this subject has mysteriously 'gone quiet' in America. That is often a sign that the security agencies are working on it, or if not working on it, then actively suppressing it for some paranoid reason of their own. (How dangerous can it be for the public to know about superconductivity taking place within the human body?) But several decades of silence is extremely annoying, especially in light of the crucial importance of this almost-forgotten subject.

What does all of this mean for our discussion in this book? It is fundamental. We are looking at the dynamics of currents of electricity and proticity within our bodies, an interface between the plasma inside us and our physical bodies – and also, as Cope's work suggests, between our plasma selves and universal electromagnetic fields and perhaps microwaves. In other words, Cope discovered a plasma-based mechanism by which our physical bodies are affected by fields.

As we will see later, quantum biologists have shown that some birds navigate their migrations by means of interaction with the Earth's electromagnetic fields, which have now been shown to cause chemical changes in their brains. Could this interface identified by Cope also work in much more subtle and complex ways in the human brain and account for important features of own consciousness and behaviour?

This subject needs to be investigated continuously and relentlessly. Either it has been done in secret, in which case the facts need to be made public, or it has not been done, which would be a major dereliction.

In 1989, an unexpected contribution to this subject appeared from Europe. A group of five authors prominent in biophoton research published a paper supportive of the idea of superconductivity in organisms. They were Emilio Del Giudice, Silvia Doglia, Marziale Milani, Cyril W. Smith, and Giuseppe Vitiello. I have had very friendly and productive relations with Smith and Vitiello for some time by email, but missed the brilliant Emilio Del Giudice, who was no longer alive by the time I established contact. Their joint paper especially dealt with Josephson Junctions in living systems.<sup>22</sup> The five authors were preoccupied by what it means for long-range order to occur by correlated behaviour of the elementary components of an organism.

The five authors say:

A living system can be considered as a set of many microscopic components whose interplay occurs through a network of mutually coupled and sequentially ordered chemical reactions. The macroscopic [large scale] ordering could be considered as emerging from the collective behaviour of the elementary components ... One of the authors [Cyril Smith] and his co-workers have, over many years, found evidence that Josephson-like phenomena are occurring in living systems. The first piece of evidence came in 1975 ... there is a small superconductive region with dimensions (which are very small) ... A dispersion of such regions ... could give rise to an a.c. [alternating current] Josephson effect ... a pair of nearby cells acts as a Josephson Junction ... (which gives) rise to an intercellular coherence.

In other words, ordered complexity is created in organisms by means of the actions of adjoining cells influencing each other across Josephson

Junctions. It was impossible for Freeman Cope to enter this discussion, because he had already been dead for seven years.

However, a year later in 1990, William A. Little jumped back into the fray, twenty-six years after his seminal paper of 1964 considered earlier. As an organizer, he took part in an International Conference on Organic Superconductors, which took place 20–24 May 1990, at South Lake Tahoe, California. This conference was funded by the deceased Freeman Cope's old employers, the Office of Naval Research, under contract N00014-90-J-1384, along with the US Department of Energy.

Bill Little, describing himself as 'Principal Investigator', wrote the necessary classified Final Report for the Navy and submitted it on November 30. This Report has now been declassified. It contains a photo of all the participants and a chart identifying them all by numbers. The papers are not included, but abstracts of them are. Little states that the Proceedings will be published by Plenum Press, and then he says:

It would be appropriate to mention two items which were brought up by the participants and which might be of interest to funding agencies. The first was a perceived need to develop a better understanding of the process of electro-crystallization ... The second, was the remark by Professor J. [James] P. Collman that the field of organic conductors, organic magnets, and organic superconductors ... appears to many to have the potential of contributing an enormous amount to the development of new materials of commercial value in the coming years ...

When the Proceedings of this conference were published, containing all the papers, <sup>23</sup> none of these remarks or the photo appeared. In a brief preface about the history of the subject for the preceding twenty-five years, Little does not mention a single one of Cope's papers, or indeed any of the other papers we have considered here except his own of 1964. To me, this gives the appearance of a wish to conceal the earlier history of the subject rather than to reveal and discuss it.

In the large volume, Josephson Junctions are mentioned only once,<sup>24</sup> and the conference as a whole appears to have taken place in a parallel universe where all that we have considered so far does not exist. And after this conference, the entire subject drops off a cliff and that is the end of it, as far as the public gaze is concerned. Perhaps 'the development of new materials of commercial value' (and probably military value as well) was the reason for this subject 'going dark' after 1990. In which case, I am glad to be resurrecting it, since probably no one else would ever have done so.

The mechanics of superconduction within physical bodies will certainly also be found in a similar form in plasma bodies in space. There can be no doubt that superconducting regions and Josephson Junction switches operate within plasma entities, and must occur in their hundreds of millions or billions (or probably trillions) within the Kordylewski Clouds. They will be fundamental to any computing powers of the Kordylewski Clouds. And there must be hundreds of thousands of them within each one of us, in both of our bodies, the physical ones and the plasma ones.

In addition to this, superconductivity is, as we saw in Chapter 8, bound to occur within the Birkeland Currents that stream through the whole of the Universe. There is no reason why such superconductivity within those galactic and inter-galactic filament streams cannot travel at speeds known as 'relativistic', meaning near to the speed of light. As we have also seen, we know the streams of electrons within the Birkeland Currents move forward in a double-spiralling fashion in counter-rotating layers. Similar filaments, operating in the same or a similar fashion, must exist within the Kordylewski Clouds, and at a micro level within ourselves. These are areas of research that need urgently to be pursued, as we need to know so much more.

I shall add just one clue as to why this subject may have been suppressed. Everything that I have described above could be exploited in the creation of robots that combine inorganic with organic components. There are people who write about 'transhumanism', which deals with this subject. The work of Cope and the others, in fact, has direct relevance to efforts to build robotic 'super-soldiers', who can enter a battlefield and kill, kill, kill. Isn't that wonderful?

## How Our Bodies Emit Light

All of us emit light, as do all living things. But it is a kind of light that cannot easily be detected. Since particles of light are called photons (a word coined for them in 1916 by the physicist Leonard Thompson Troland), those spontaneously emitted by living tissues have come to be called 'biophotons'.

Biophoton emission is not the same as 'bioluminescence', which is what we see with fireflies, electric fish and a few other creatures. It is also not the same as 'chemiluminescence', light emitted by a chemical reaction, which can also sometimes be seen taking place in living things. All those emissions of light can be seen by the eye. But biophotons cannot.

Biophotons are emitted when electrons in the organism get energized or 'excited'. They are therefore useful for detection and diagnosis, and as indicators of what is happening in the organism.

Biophotons are so faint that they are what is known as 'ultra-weak' emissions of light. If something is ultra-weak, then surely, you might say, it is of no importance. But nothing could be further from the truth. We have good reason to believe that biophotons are fundamental to our existence. And when the emission of biophotons by our bodies goes wrong, it means that we have a serious illness.

It is now known, for example, that changes in biophoton emission rates are the earliest possible sign of cancer. So early is their warning that millions of lives could be saved or significantly extended if a mass biophoton detection programme were adopted. With such extremely early warnings, incipient tumours could be removed before they became dangerous, when they were still only a few cells in size. (Such tiny incipient tumours can easily be zapped and destroyed by ablations, using keyhole

surgery.) Biophoton detection is not invasive and does not require expensive scanners. It does not bombard the body with radiation. It is an entirely passive process. It need cost very little. Indeed, it can be done by a simple blood test.

At the present time, only one machine exists in the world for taking these images. Biophoton research is barely funded and is ignored by all the world's governments except the Dutch, which is strange, considering that cancer prevention at an early stage could save such gigantic sums of public and private money in treating cancers. In fact, the world's medical insurance companies should sponsor mass biophoton detection to increase their business profits enormously.

For a large-scale biophoton scan of, say, half of the body, the person needs to sit in complete darkness for at least half an hour in order for residual light effects to dissipate. After that, it takes some considerable time to wait for the ultra-weak emissions to register. Here is an image of the head and torso of someone in total darkness, with spontaneously emitted biophotons as the only light source for the image:

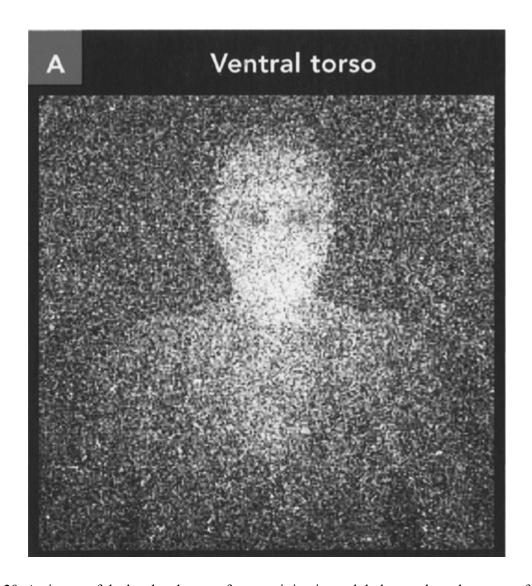

Figure 29. An image of the head and torso of a man sitting in total darkness, the only source of the light forming the image being the spontaneously emitted biophotons coming from his own body. For reasons that are not entirely understood, the eyeballs do not emit many photons, and so appear here as dark holes. Image courtesy of Professor Roeland van Wijk.

There is another way to detect biophotons by means of a portable detector with two long empty gloves hanging from the front. A person inserts his or her arms into the gloves, which reach to the elbow. The hands, being entirely in the dark inside the small machine, then have their spontaneously emitted biophotons counted by the machine's twin photomultiplier detectors. Just from counting the biophotons coming from the hands, it is possible to know whether a cancer condition is developing somewhere in the human body. A 'positive' finding then suggests that more tests should

be carried out to locate it. A 'negative' finding suggests that they are probably unnecessary and there is no cancer condition.

The main basis for this is that 'changes in ultra-weak photon emission occur in the transition from a healthy to a diseased state.' And this is the earliest warning signal.

Biophoton research, despite all its promise, has been shrinking, not expanding. There is little or no funding for it. Public health officials are too dim to see its potential, and it is 'outside their comfort zone'. Big Pharma is never going to promote it, and most doctors don't know about it. The heyday of biophoton research was in the 1990s, when many publications on the subject appeared. But at that stage, the detectors mentioned above did not yet exist, so all that was written was based upon laboratory research, and the equipment was not yet in existence for public use.

The big-name researchers in the field at that time have mostly died or retired by now, and have not been replaced. One can go down the list of names prominent then, and one soon discovers that only a few are still alive, and several of those have become inactive because they could not find anyone to fund their work. The combined knowledge of several brilliant scientists from many countries is in danger of being lost to humanity through ignorance and prejudice. And the price of this ignorance and prejudice is that many, many people will die needlessly.<sup>2</sup>

The leading proponent and researcher of biophoton technology for human health today is probably the Dutch scientist, Professor Roeland van Wijk (known as Roel). Although he is now retired, his son Dr Eduard van Wijk leads a group at Leiden University in the Netherlands, to which his father is a leading scientific advisor. They are actively researching biophotons, and are apparently the only group in the whole of Europe doing so. Roel did important work earlier with another such group in Japan, headed by Masaki Kobayashi of Tohoku Technical University at Sendai.

In 2014, van Wijk published a mammoth book on biophotons in biology and medicine, which is extraordinarily clear and explanatory.<sup>3</sup> It can easily be read by any medical doctor or person with some basic education in biology. It is described as an interdisciplinary textbook, and the hope is that some academics somewhere will actually use it as such. In any case, the book exists, and van Wijk has done the public a great service. However, the

number of copies available is now very small, so that the book is not achieving the wide circulation it urgently needs.

Biophotons were first discovered in plants by a brilliant Russian scientist, Professor Alexander Gurwitsch (1874–1954). (Gurvich is the correct Russian spelling, but he is more widely known as Gurwitsch, the spelling used for his German publications.) While studying the growth of onion roots in 1923, Gurwitsch was able to demonstrate the existence of biophotons, though he did not call them by that name.

Gurwitsch's theory was that organisms grew in connection with fields of some kind, which he named 'morphogenetic fields'. He was the first person in history to use the term 'field' in connection with biology, in a paper concerning the growth and development of embryos, which he commenced writing in 1911 and published in 1912. But at that stage of his work, he had no proof, only a theory. It was only in 1923 that he was able to demonstrate physical evidence for his theory. He had already concluded that cell division (known in biological terminology as 'mitosis') in embryos must require not one, but two, factors.

The first was a 'possibility factor', meaning that the circumstances must become such that cell division was rendered possible. The second was a 'realization factor', meaning that the cell division, having become possible, was then somehow triggered. Without this trigger, it simply would not take place. He did not believe that this trigger was chemical. Instead, Gurwitsch decided that the way the organism as a whole triggered cell division for its embryonic cells to divide and grow must take the form of external non-chemical signals of some kind. But what could they be, and how could the signals be detected by the cells?

He decided that each cell membrane must be 'an organ perceiving signals for cell divisions'. Gurwitsch became the first person in the history of biology to use the term 'receptor'. He suspected that the cell membranes must contain 'receptors' of some kind to detect signals of some kind, to cause cell division, which he called 'mitotic signals'.

Gurwitsch then carried out his now famous onion experiment, studying the growing tips of onion roots. (A drawing of the experimental setup is to be found on this book's website.) The roots had to be as even and smooth as possible, and were placed at right angles to each other so that the tip of one root was directed precisely at the zone of the other where cell division would take place. He found that the tip of one onion root, which he called the 'inducer', when directed at the wall of the other onion root, which he called 'the detector', induced more cell divisions on the side of the detector root that faced the inducer root than it did on the shadow side.

This led him to believe that some kind of signals (which he called 'external impulses') were being sent, affecting the near side much more than the opposite side. It was as if the near side was in the light and the far side was in the shade. Then he had the extraordinary idea of inserting first a glass plate and later a transparent quartz plate between the two roots. He discovered that the glass plate blocked the signals, so that no cell division ('mitogenetic activity') took place in the detector root. But the quartz plate did not block the signals. This unexpected and bizarre finding ruled out chemical or mechanical signals, since the signals were not blocked by quartz.

It quickly became apparent to Gurwitsch that the mystery could be solved only by postulating that the inducer roots were emitting photons in the ultra-violet range, and that those were the signals in play. As most people know, UV radiation from the Sun does not penetrate glass windows, which is why we do not get sunburn indoors even if we are sitting under a glass roof in the blazing sun. But ultra-violet radiation does penetrate quartz.

Gurwitsch called the ultra-violet signals 'mitogenetic rays', because they were rays causing cell division, i.e., mitosis. (As I mentioned earlier, the word 'photon' for light particles had only been coined in physics seven years earlier, in 1916, and it was not yet in common use, so the idea of calling his rays 'biophotons' did not occur to Gurwitsch. It was the German Professor Fritz-Albert Popp who introduced the term 'biophotons' in the 1970s to replace the terminology 'mitogenetic rays'.)

A fascinating account of the history of Gurwitsch's work and discoveries was published in English in 2007 by his grandson, Professor Lev Beloussov, jointly with his colleague Professor Vladimir Voeikov, entitled 'From Mitogenetic Rays to Biophotons'. In this account, they explain that Gurwitsch looked for the evidence in order to support a theory he had formed, and how he found it. Lev and I were in touch and commenced a joint effort to preserve all of Gurwitsch's writings and place them on the internet. He was extremely enthusiastic about this. Suddenly he died of a

heart attack. But his efforts are being continued by his student and protégé Ilya Volodyaev, with whom I now cooperate in this. We are making good progress in preserving the material that is in Russia.

There was tremendous enthusiasm for Gurwitsch's discoveries, and Gurwitsch was nominated for the Nobel Prize in the 1920s and on numerous occasions over the years thereafter. Between 1923 and 1939, according to Beloussov, more than seven hundred papers on the subject appeared, as well as books.<sup>5</sup>

Gurwitsch wrote in Russian and in German and very little of his work has ever been translated, but in the 1930s his work became accessible in Europe thanks to the appearance in German of one of his main books, written jointly with his wife and scientific collaborator Lydia Gurwitsch, *Die Mitogenetische Strahlung (The Mitogenetic Rays)*, published in Berlin in 1932. But by 1939, the Second World War brought about such chaos that communications and academic exchanges were interrupted, especially with Germany. Gurwitsch was awarded the Stalin Prize in 1941, but after the war his work was forgotten thanks partly to the Cold War between the Soviet Union and the West.

Furthermore, from 1942 Stalin's favourite and wholly dominant pseudo-scientist Trofim Lysenko began to persecute Gurwitsch, so that Gurwitsch was not allowed to work in any laboratory and became a political pariah. Gurwitsch's ideas thus dropped out of sight. My friend Joseph Needham, whose colleague I had the honour to be for some years from the mid-1980s, presciently supported Gurwitsch's ideas in 1950,<sup>6</sup> but this unfortunately had no significant effect on the widespread ignoring of the subject subsequent to 1939.

Gurwitsch also discovered that the emission of the ultra-violet photons must be coordinated by the whole organism, which he attributed to its morphogenetic field, in line with his pre-existing theories. He was extraordinarily prescient in this, because the work in physics had not yet been done to explain the mechanics of how such a field might work. It was only after his death that the concept of 'coherence' (in the specialist sense of waves having the same characteristics, such as phase and frequency, within a spatial area, as distinct from its better-known usage to describe

'superposition' in quantum mechanics) emerged in physics, as a result of a paper published by Robert Dicke in America in 1954.

This coherence only became a concept in biology many years later, which then made it possible to put some flesh on the bones of Gurwitsch's field theory. It is not granted to us all to live long enough to see our theories justified, and Gurwitsch did not have this good fortune. But in trying to figure out the mechanics of the process, Gurwitsch was ahead of his time, and became the first person to suggest the existence within organisms of what we now call 'collective states' and 'cooperative phenomena', but which he called 'states of mutual alignment and orientation of molecules'.

He suggested that this was associated with a redistribution of energy within the organism in an organized fashion at the macroscopic scale, and that chain reactions of signal propagations took place. It was the spatial organization of the whole organism that was important, and it superseded the importance of individual atoms and molecules, demonstrating to him the existence of biological fields.

All of these ideas now exist in far more sophisticated form, substantiated by a huge amount of experimental work. But 'mainstream biology' and 'mainstream medicine' show no knowledge or recognition at all of this progress. With one exception that I know of (a large grant by the Dutch Government), there are no grants or funding anywhere in the Western world for biophoton research. Scientists cannot yet live on air, and until they invent a way to do so, they must either starve or abandon their biophoton work. And biophoton work takes laboratory time, and needs assistants, and then the findings need journals willing to publish the results.

So difficult was it to find journals willing to publish biophoton findings even in the heyday of biophoton research that the small but international biophoton research community had to adopt a different strategy to achieve publication and get around the roadblocks of the unwilling journals. They held numerous international biophoton conferences, gathered up the papers of the speakers, and published them in volumes of conference Proceedings, and sometimes anthologies of papers were also published without an underlying conference as a source. The majority of the conferences were held in Germany and Russia, but the papers were published in English.

So underfunded were these endeavours that many of the papers translated into English by their non-English-speaking authors have poor grammar and

spelling, and strange phraseology and usages replicating those of the native languages of the authors, because there was no money to pay for most of the volumes to be copyedited or proofread. In quoting from some of these publications, I shall therefore correct their English, and thereby clarify their meaning. I shall do this in the rest of this book, simply for the sake of clarity.

This defect of language is particularly true of one of the most interesting biophoton books of all, *Current Development of Biophysics*, published in 1996 by Hangzhou University Press in China. The book is very rare, but it contains some of the most important insights relating to biophotons ever published.<sup>7</sup>

It had three editors, two of whom I know. The third editor was Professor Fritz-Albert Popp, whom I was never fortunate enough to meet because of his many years of debilitating illness before his death. The others were Marco Bischof and Zhang Changlin (I give his name in the Chinese form, with the surname first). Both of them are absolutely delightful men of warmth, humour, and brilliance of mind. Marco is a great scholar of the history of these subjects, who has been tireless in writing and publishing on the subject such fundamental, incisive, and broad surveys that they shall remain classic accounts for ages to come.

Leading international biophoton researchers who contributed to that volume were Popp (one of whose most important papers appears in it); Poland's leading researcher, Professor Barbara W. Chwirot; Gurwitsch's grandson Lev Beloussov from Russia; Professor Roeland van Wijk; Professor Ke-Hsueh Li of the Chinese Academy of Sciences; and Professor Michael Lipkind of Israel, whose paper was entitled 'Application of the Theory of the Biological Field of A. Gurwitsch to the Problem of Consciousness'.

In the attached footnote, I give a list of important books on biophotons in English, many of which are extremely difficult to find, but all of which are of great importance. I have listed them chronologically by the dates of their publication.<sup>8</sup> A list of some important biophoton books in German that have never been translated into English is also included here.<sup>9</sup> (These bibliographies are to be found on this book's dedicated website.)

There are in addition numerous volumes not specifically devoted to biophotons, such as those concerning coherence in biological systems, which are nevertheless highly relevant and contain important material relating to biophotons. Some of these will be cited in the closing portion of this book, where physical 'coherence' is stressed in a wider context. And of course there is the book by van Wijk of 2014 already referred to, as well as a sequel volume by him, which appeared in 2017.<sup>10</sup>

It is important to tell people where to find information about this 'suppressed subject', as it took me a long time to discover and obtain all of these books, and it is not easy to do so. I therefore hope I have made it easier for others by listing them.

The biophotons themselves are only part of a much larger picture, which took shape largely as a result of studying the biophotons. It was the brilliant Russian scientist Viktor Mikhailovich Inyushin, who pushed the boundary much further in his writings about 'bioplasma'. This term 'bioplasma' was coined in 1944 by the Russian scientist V.S. Grischenko (aka Grishenko). By 1967, Grischenko and Inyushin were working together on bioplasma, and they announced then that they envisaged a plasmatic state within living organisms which, in contrast to inorganic plasma, would be a cold plasma possessing a high degree of order.

This was an interesting idea, for the cold plasmas in space, such as the Kordylewski Clouds for instance, are more likely to be intensively ordered and to show 'emergence' and self-organization, and indeed inorganic life. One would not normally think that the human body could contain a cold plasma, which seems counterintuitive, considering how warm the body is.

But Grischenko and Inyushin worked out that this is possible. And what is more extraordinary, as we will see in a moment, they believed that this cold plasma would chiefly be found in the brain. So, to make it clear, bioplasma is the name they gave to that plasma which, they were convinced, joined with the physical body and helped it to operate, or even coordinated and guided its growth and development.

This idea was essentially the same as Aristotle's pneuma (<a href="here">here</a>). Just to remind the reader, Aristotle believed that aether existed beyond the Earth's atmosphere and was a 'fifth element', and that pneuma was a somewhat inferior form of aether that actually was found inside physical bodies and

helped to animate them. Grischenko and Inyushin, doubtless without realizing it, have duplicated Aristotle's reasoning and consider plasma to exist in space, and bioplasma to exist inside our bodies (hence the 'bio-' prefix). And one of the manifestations of the bioplasma is the emission of the biophotons.

This was a concept where for every organism's plasma body, biophotons would just be one manifestation. Very few Western scientists were ever allowed to meet Inyushin, since he was considered by the former Soviet Union to be their most brilliant and important expert in the field of parapsychology, with its many military applications such as 'remote viewing'. His existence first became known to the outside world in the 1970s, and in 1977 a tantalizingly brief article by him of only five and a half pages appeared in English translation in the compendium *Future Science*, entitled 'Bioplasma: The Fifth State of Matter?' <sup>11</sup> In this, he says:

A living organism can be described as a 'biological field' or 'biofield' ... we have obtained evidence that a fifth state of matter, bioplasma, exists as a part of each organism's biofield. Bioplasma consists of ions, free electrons, and free protons. It is highly conductive and provides opportunities for the accumulation and transfer of energy within the organism as well as among different organisms. Bioplasma appears to be concentrated in the brain and the spinal cord. At times, it may extend considerable distances from the organism, raising the possibility of telepathic and psychokinetic phenomena.

It was the latter aspects that so interested the military and security services of the Soviet Union, in connection with what they called 'psychotronics', and they were careful to keep Inyushin under wraps, whereas other less important scientists in this field such as Viktor Adamenko were allowed to mix with Western investigators.

Inyushin had known the Kirlians, a husband and wife team who were the inventors of Kirlian photography, as they were his neighbours when he was young. As a boy, he had sometimes assisted them in their work. He thus built up a lifetime's background in investigating and experimenting with strange phenomena relating to living organisms of all kinds, including humans, especially psychic humans of the type of the American Ingo Swann, but only those who were within the Soviet Bloc, such as the famous Russian psychic Kulagina.

The Soviets had some truly spectacular people of this kind, who were the best recorded cases of psychokinesis, which means the ability to move physical objects around by the power of the mind alone, without touching them. It was Inyushin who provided the scientific theory to explain all of this. And that theory was a highly elaborate one that developed out of ideas of bioplasma.

Very little of Inyushin's work has ever been translated into English, except for secret translations that have never been released by the American security agencies. I have some privately translated writings of his, the earliest of which dates from 1969 and concerns acupuncture. These translations (in very poor English) were commissioned by my friend Marco Bischof, and he kindly let me have copies. Inyushin's work also related to biophotons, and as he wrote in his 1977 article: 'Our experiments with light indicate that bioplasma is especially conductive for photons in the ultraviolet range.' That is precisely what biophotons are, photons in the ultraviolet range. And he adds: 'Our group has hypothesized that an organism's bioplasma is an important factor in ... the emission of light from an organism from causes other than high temperatures.'

Inyushin's concept of a bioplasma body accompanying the physical body (which we might also call a 'dense matter body') will come back into the discussion in the next chapter. His bioplasma theory follows Gurwitsch's suggestion that biomolecules in the organism are predominantly present in the 'excited state'. I am again using the term 'excited state' in a quantum physics sense to mean that a system, or an electron, has absorbed energy and entered a state of having higher energy than normal. In Inyushin's account the energetics of living systems are based on excitation—deexcitation dynamics. Inyushin describes bioplasma as a 'cold' plasma of highly structured collective excitations produced by the polarization of biological semiconductors. In other words, the energies in bioplasma bodies are dynamic grids of excitations—which interact with fields outside the body.

In 1967, at the same time that Grischenko and Inyushin were announcing their bioplasma hypothesis, the Polish biologist Włodzimierz Sedlak (1911–1993) independently came up with his own bioplasma hypothesis as well. He and Inyushin later got together and worked on the idea jointly. This was facilitated because at that time Poland was part of the Soviet Bloc so that

their mutual cooperation was considered acceptable by the authorities. Inyushin himself lived in Alma Ata in Soviet Kazakhstan. Inyushin also researched biophotons.

According to the bioplasma studies of Inyushin and Sedlak, the plasma particles constituting the bioplasma in the body set up highly structured waves of excitation, that, as we have just seen, serve as an energy network. The energies stored in the network form an internal 'biological field'. Remarkable as it may seem, this 'biological field' has a complex broadband wave structure of great stability that stores holograms.

In exploring the complexities of plasma in the body and its connections with consciousness and images in the brain Inyushin and Sedlak are here leaning on the work of Professor Karl H. Pribram (1919–2015) who originated the 'holonomic brain theory' to explain consciousness, using the idea of holographic memory.<sup>12</sup>

Most people today are familiar with holograms, and are aware that the making of holograms (holography) has something to do with light rays, though they may be vague about how it all works. A hologram made by this method is a 'picture' not of an actual image, but instead of a light-wave interference pattern. When the pattern is activated then the image appears in a three-dimensional mode. The internet is full of explanations of how this is done. However, what few people realize is that holograms can be made without the use of light rays.

Karl Pribram explained this at length as long ago as 1971 in his technical book *Languages of the Brain*.<sup>13</sup> He believed that holographic processes operated within the human brain, and were used in the storing and activation of memories in particular. Pribram said:

Optical systems are not the only ones that can be subjected to the holographic process ... Holograms are thus not dependent on the physical presence of 'waves' ... This independence of holography from physical wave production is an important consideration in approaching the problem of a neural holographic process.

Clearly, it would take too long to summarize here Pribram's theory of the brain-as-a-hologram, about which many books have been written, not least by Pribram himself. But it is important to realize that enormous intelligences in the Kordylewski Clouds would probably have fantastically advanced holographic capabilities, which would be used not only to store

their massive amounts of information, but also to generate images in any form, whether as wave-forms, pure data, or optical images that could be seen by the eye (if there are any eyes in the clouds). Technically, none of this poses any problem. The clouds would readily be able to extract 3-D images of the kind familiar to us and transmit them to our brains if they wished to do so. We could even make a pun and call this 'Cloud holography', and the cloud in this case, of course, is not owned by Apple.

Another Polish researcher, Adam Grzegorz Adamski, says that a lot of bioplasma is stored in melanin, which as most people know exists in the skin and protects us from ultra-violet radiation by causing us to get tan or brown. He says:

Melanin is not only a semiconductor, but also a room temperature superconductor ... Melanin accumulates in the cells of the nucleus, where the genetic material (DNA) is, in order to protect the genetic code from the damage from UV-rays ... These properties of melanin reveal that it has large resources of bioplasma ... With the semiconductor properties of proteins and melanin electrons can travel over long distances without losing energy ... Bioplasma is understood as a dynamic system in an organic semiconductor ... The total energy of the bioplasma consists of thermal motion, kinetic energy of particles, floating particles, the electric field, the magnetic field, and solitons. <sup>14</sup>

We can see how like so much else these studies draw heavily upon the early pioneering work by Albert Szent-Györgyi, who was the first person to insist that the body contained organic semiconductors, as I have already described. Just as the work of Alfvén and his followers has revealed the complex, living reality of outer space, and the interactions there of plasma and electromagnetism, so his fellow Nobel laureate Szent-Györgyi and his followers have revealed the immensely and astonishingly complex operations of electromagnetism and plasma within the human body, and outside it too.

Returning briefly to the subject of biophotons, when they are seen being emitted from acupuncture points and meridian lines, they are not a sign of cancer at all, but rather an indication of the normal heightened activity in those key regions of the body. Biophoton scans actually give clear visual images of the mysterious flowing body energy (doubtless a flowing plasma) known as qi (pronounced 'chee') in Chinese acupuncture. These streams inside the body, which have been detected frequently, are known as 'light-piping', more technically described as 'channels of light emission'. Such

channels form a meridian network. This is one of the most important areas for research, since its findings clearly validate the Chinese system of acupuncture points and meridians in the body. The light pipes and the traditional acupuncture meridians are the same.

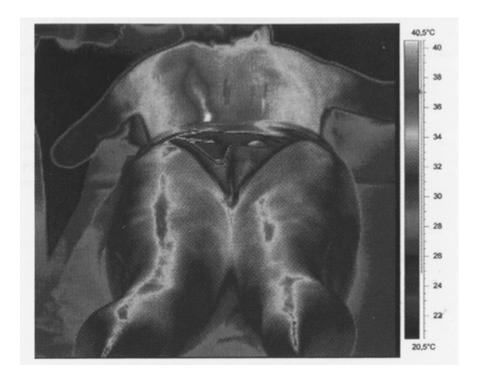

Figure 30. Biophotons being emitted along the meridians of the backs of the legs. Image courtesy of Professor Roeland van Wijk.

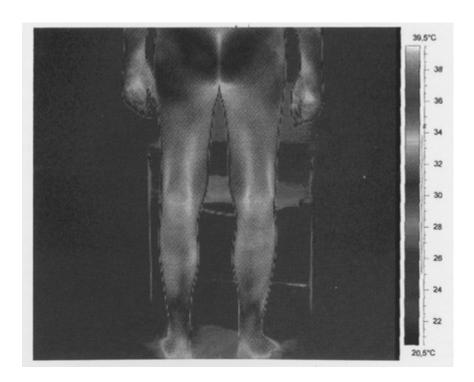

Figure 31. Biophotons along meridians of the legs seen in the standing position. Image courtesy of Professor Roeland van Wijk.

As we build up a picture of the role of plasma within human bodies and consider the idea that plasma may provide a medium for interaction with universal fields, we see again that ancient wisdom anticipated cutting edge discoveries in modern science.

# The 'Death Flash' and the 'Life Flash'

In the previous chapter we looked at the role that plasma has inside the body – forming and regulating it and maintaining health. In this chapter, we will look at it in relation to death.

It has been said that at the moment of death, a flash of light is emitted by the body. There are many reports of this. It applies to all living organisms, not only to people. The evidence concerning this flash of light is extensive, and the speculations concerning it have entered into works of fiction and film.

This is one of the most important details about the relationship between the physical body and any animating plasma body that may co-exist with it. It is what has come to be known as the death flash.

In case there are misunderstandings, I should point out that, apart from the exceptions described below, the only spontaneously emitted light from our bodies consists of biophotons, as was discussed in Chapter 15. They cannot be seen by the eye because they are what is called ultra-weak and low intensity. It only became possible to detect them at all after the laboratory devices known as photo-multipliers were invented in the 1950s.

Let us find out more about the 'death flash', however, because although it cannot be seen by the unaided eye either, apparently it is followed by a faint mist that is visible to the naked eye, but only for an instant, and you have to be looking intently at where it is about to happen just when it does.

The Polish biophoton researcher, the late Professor Janusz Sławinksi (1936–2016), published a summary of many of the occurrences of the 'death flash', technically known as 'necrotic [from *nekros*, the ancient Greek word for a dying person or human corpse] photon emission', with his extensive comments, in 1987. In it, he says:

All living organisms emit low-intensity light; at the time of death, that radiation is ten to 10,000 times stronger than that emitted under normal conditions. This 'death flash' is independent of the cause of death, and reflects in intensity and duration the rate of dying. The vision of intense light reported in near-death experiences may be related to this death flash, which may hold an immense amount of information. The electromagnetic field produced by necrotic radiation, containing energy, internal structure, and information, may permit the continuation of consciousness beyond the death of the body.

This is clearly very important information. Considering how terrified most people are of dying, you would think that this information would be more widely circulated, if only to assuage people's anxieties. But strangely, few people have heard about it. This is puzzling to me. I think it must be because we live in a world today where intellectuals, mainstream social opinion-formers and mass media all subscribe to a rigidly materialistic view of life, and are intolerant of anyone who challenges this arid position in even the slightest way.

The first time I came across the idea of a 'death flash' was in a work of fiction. In his 1931 novella *The Weigher of Souls*, André Maurois adopts his own persona as the first-person narrator.<sup>2</sup> He says he has been a French liaison officer with the British and that the British officer with whom he shared a tent was a medic named Dr H.B. James. That is how the strange adventure begins, for the narrator comes to London after seven years of not having seen Dr James and decides to look him up.

The action is thus set in London in 1925, and the novella is consciously written in the style of an Edwardian mystery or science fiction story, heavily influenced by Conan Doyle and H.G. Wells – the reader half expects Sherlock Holmes to appear, or a time machine to be mentioned. But Maurois has a much more subtle tale to tell than at first appears. Dr James is working at 'Saint Barnaby's Hospital', a very Victorian establishment on the South Bank of the Thames. London is described in the best Conan Doyle tradition as covered with fog:

Whilst we had been dining, a thick fog had come down over the streets. The gleaming headlights of invisible cars planted it with rings of red and white light. Ludgate Circus was a landscape of nightmare. James bade me take his arm and guided me towards a bus ... The bus crossed the river in the midst of a veritable bank of yellow cotton wool. Factory fires on that baleful shore gleamed vast and pale through the flocculent gloom ... The lights of the hospital shone feebly in the enveloping cloud ... My companion's nervous state seemed to be one of violent overexcitement.

James has become such a haunted and distracted person, so different from the narrator's jolly wartime friend, because he is engaged in forbidden experiments, which he carries out in the morgue of the hospital at great risk of being discovered. He has discovered that something strange happens at death and he wants to investigate it. He says he got the idea from experiments carried out by Sir William Crookes, one of Victorian Britain's most distinguished scientists, who later in life developed an interest in spiritualism (discussed earlier in Chapter 3). James explains:

'I once read an account, in a medical paper during the War, of an experiment made by a certain Dr Crooks [sic – it should be Crookes, and I see that the misspelling occurs also in the original French edition]. He described how he had weighed the corpses of animals, and had observed that, after a period approximately regular in a given species, there was an abrupt drop in weight ... In a man he reckoned this fall as averaging seventeen-hundredths of a milligram. From which he concluded that the soul does exist, and that it weighs seventeen-hundredths of a milligram ...

'Last year, as circumstances and hospital routine placed corpses at my disposal, it occurred to me to verify the facts registered by Crooks; and with some surprise I discovered that he had told the truth ... Only, he had stopped the experiment too soon. In man the normal curve of evaporation is almost always interrupted, not once, but three times by sudden falls ... The first, which you have observed to-night, takes place about one hour and thirty-five minutes after death, and is between fifteen- and nineteen-twentieths of a milligram; the second and third ... follow the first at intervals of twenty minutes and one hour respectively ... regarding the results of the experiment, no doubt is possible ...

'Let me add that I have repeated them with animals – whence the rats which intrigued you. And there, too, Crooks's results are correct. There is always a sharp drop, but its extent is very much less than in man ... Such are the facts; the interpretation, of course, admits of argument ,'

His pipe had gone out. He relit it and looked at me. I was careful to say nothing. He continued:

'At this stage, this is what I put forward. It seems to me possible to suggest, not that the soul weighs seventeen-hundredths of a milligram, but that every living creature is animated (in your language you could almost say âme) by a certain form of energy, still unknown, which leaves the body after death. That all energy possesses mass is something admitted by the post-Einstein physicists. You know that light can be weighed, and that theoretically light could be compressed in a receptacle ... Well, why not vital energy likewise?'

James decides that he wants to catch the mist that rises from a person who has just died in a glass receptacle. This is what he believes has the slight weight. And as a scientist friend of the narrator says: 'Why shouldn't there by "psychons" as there are electrons?"' James wants to capture the evanescent psychic substance of a dying person, and keep it captive to study it. He makes it visible by ultra-violet light in an otherwise dark room. He succeeds in capturing the spirit of a dead rat in a glass bell jar.

The narrator sees it in the dark as a faint glow, about the size of a nut, but more elongated: 'Going closer, I saw that the interior of this luminous kernel contained darker currents revolving extremely slowly. The whole thing reminded one of the appearance of certain photographs of celestial nebulae.' Remember the whirling plasmoids of Bostick that we encountered earlier, which he compared to galaxies?

The story gets weirder and weirder. At last, the narrator is present at the death of a human being, and James has his glass bell jar ready. Maurois says:

I saw a faint blue mist appearing. At first it seemed shapeless and as if diffused ... (then) the vapour became condensed in a milky mass, about four inches long, the base of which was horizontal, with its rounded top following the curve of the globe. Currents of lighter and darker colour were visible in it ... until they formed an object of well-defined outline ... (a) ball of light.

I do not wish to spoil the enjoyment of anyone reading the novella by saying what happens as the story progresses. But it does become increasingly bizarre.

Subsequent to the appearance of this novella, and perhaps partially because of it, a legend was born that each of us has a soul that weighs 21 grams. Although largely unknown in the English-speaking world, there were some French intellectuals who became interested in 'the weight of the human soul'. One of these was Wilfried-René Chettéoui, who had been influenced in his thinking about the soul by studying the Siberian Shamans (about whom he published a book in 1947) and who wrote in a paper published in 1986:

Various investigations established the weight escaping at the moment of passing to between 60 and 70 grams, The quantity of spirit is without mass, and consequently the weight of a spiritual being is almost negligible.<sup>3</sup>

Much better known than any experiments by Sir William Crookes were those carried out in America by Duncan MacDougall (1866–1920) in 1901. He weighed six dying human patients, five male and one female. He calculated the weight of the human soul at between six and eight ounces. He also tried to photograph the escaping human soul from dying persons. But as we now know, if one is looking for a light flash (a biophoton flash), it is too faint for the human eye or any normal camera to detect, even

though it may be, as Sławinski discovered, as much as 10,000 times stronger than a biophoton is normally. But even that remains 'ultra-weak', as all biophoton emissions are.

One presumes that the faintly visible mist follows the ultra-weak 'death flash', and escapes the body by floating upwards. The 'death flash' presumably heralds the commencement of the process of death, and the 'mist' completes it. By 1907, MacDougall had refined his estimate of the weight of the soul to 21 grams (about ¾ of an ounce), 4 which is where that value originated. This was the source of the title of a 2003 film starring Sean Penn, 21 Grams, which popularized the notion that the human soul has a tiny mass.

I might mention in passing also that the ancient Egyptians depicted the weighing of the human soul in a balance against a feather (representing Truth), and they maintained that if the soul were heavier than that feather it would be annihilated. Presumably at 21 grams it would just squeak through.

Inevitably most descriptions of a faint mist leaving the body of a dying person come from relatives or friends who have been sitting near a dying person, often in hospital. Here is a typical example of such a story, recounted by a woman who lay in one bed of a double bed room in a hospital, of what she saw happen to the older woman in the other bed about midnight; she related this to her daughter the next day, who wrote it down:

Late one night shortly after twelve o'clock, my mother lay awake. Suddenly, she told me, she felt her attention drawn to Mrs Melberger's bed. As she watched, she saw a white mist arise from her head. It hovered for a few seconds, then slowly began spiralling and floated away from the woman and out through the closed door of the room.

The woman then fell asleep and when she woke up in the morning the bed opposite her was empty, and the nurse told her that Mrs Melberger had died a little after midnight.<sup>5</sup>

Obviously it is impossible to carry out laboratory experiments on dying people in order to look for mists, so it is difficult to imagine how this phenomenon can ever be 'scientifically proved', no matter how many accounts exist. It is easy to debunk such accounts if one has fixed ideas that no such thing can happen. It is equally easy to believe everything if one has fixed ideas that anything of that kind is possible.

I have no personal experience of this. I only sat beside a dying person once, the author Rosamond Lehmann, but I summoned a doctor and left before she actually departed a short while later. (Ironically, she had a passionate belief in the survival of death and was a member of the Society for Psychical Research.) It is because people essentially believe what they like when evidence is subjective that I have excluded my own subjective information from this book.

In addition to the visual observations of a faint mist leaving the body at death, there have been other strange observations under more controlled conditions. In 1970, Ostrander and Schroeder, who interviewed many Soviet scientists, stated that some of the scientists had taken many photos of dying animals and plants using Kirlian photography and other techniques. One of the scientists involved in these studies was Professor Viktor Mikhailovich Inyushin, who as we have seen, knew the Kirlians when he was a child, and who originated the concept of *bioplasma*.

Here is what Ostrander and Schroeder said:

[I]n the course of their extensive research with the Kirlian process, the Soviets have many times photographed the moment of death. Little by little as a plant's or animal's physical body dies, Russians saw sparks and flares of the bioplasmic body shooting out into space, swimming away and disappearing from sight. Gradually there was no luminescence at all coming from the dead plant or animal. Meanwhile, biological field detectors at a distance continued to detect pulsating force fields from the now dead body. Is this energy coming from the dispersing bioplasmic body?<sup>6</sup>

Although this account refers only to studies of the deaths of animals and plants, I have found an account of studies of humans in a rare book published in English in Russia shortly after the fall of the Soviet Union by Dr Konstantin G. Korotkov, then a young scientist who had only recently completed his PhD.<sup>7</sup> He describes his studies with colleagues using something called the 'gas discharge visualisation (GDV) technique' to study energies in living beings. The technique involves placing fingers on glass electrodes that are then supplied with a high voltage and high frequency pulse. The electric discharge around the finger produces light that is digitally photographed and sent to a computer, where special software does quantitative analysis of the numerous parameters.

Korotkov tells us in his book (I have had to make a few grammatical improvements because the English was flawed):

Does the life of the soul end with death? What should we expect beyond the threshold of this world? These problems, which have always beset mankind, are again making their appearance on the European intellectual horizon. Religions and esoteric knowledge have always taught that death is much more than merely a transformation of living material into dead material. Now that recollections of people who have experienced clinical death [NDEs, or near-death experiences are here referred to] are becoming accepted as real, the question of survival of some vital elements is entering the realms of science.

Many of the physicochemical processes occurring at the time of death are known. These changes proceed in linear fashion with the gradual process of destruction and decomposition. The Gas Discharge Visualisation technique, however, goes beyond the classical biochemical approach, to reveal some aspects of energy and information in the living body. This being so, it became of great interest to find out how this changes after death. In this way we might gain information of how the transition from the dying state to death takes place. The experiment was organized as follows:

A special group of doctors and assistants took part in every experiment. The selected [human] body was transported to the experimental room and was placed in a definite position. The left hand was installed in a definite position on an electrode and was fixed by a special device that ensured a stationary position of the hand and the fingers during the experimental session. The discharge Kirlian photos of four fingers (excluding the thumb) of the left hand were taken every hour during the day and during the night.

Then the photos were processed in controlled conditions, scanned to the computer and from each image a set of parameters (area, average intensity, fractality, etc.) was calculated. Then graphs of these parameters plotted against time were created. As a result of this process we got for every experiment the [graph] curves of glow intensity changes in time during 3 to 6 days and were able to compare these curves.

The results were numerous, and are presented in the book in technical form with graphs. More than sixty scientific papers were also published in Russian over many years reporting these results. Here are the conclusions as briefly expressed in the book:

On the basis of these results we conclude that the energy-information activity of a person does not go to zero at clinical death. In some cases it continues to be present even as much as four days after death – a time when all biochemical processes characteristic of life will have ceased and been replaced with autolytic and putrefactive processes. It was particularly significant that the course of decline depended on the cause and nature of death. In some years these experiments had been reproduced both in our laboratory [at the Federal Technical University of St Petersburg], and in some others. The results were in principle the same ...

It seems, then, that traditional spiritual teachings are right in their insistence that something of a person survives after death. These results raise not only biological and practical questions, but also philosophical ones. Our common-sense materialistic view of life and death need some correction.

Since so many people who have had near-death experiences report that they 'floated upwards to the ceiling' as soon as they left their physical bodies, and looked down upon them from above, that would seem to tally with the rising mist escaping from the body. On the other hand, I have friends who

came back to life after floating up to the ceiling, so does the mist get sucked back downwards again? Clearly, we are in speculative territory here.

Sławinski published a very technical article about the death flash, complete with twenty-eight equations and nine diagrams, in 2003 in the large volume of papers entitled *Integrative Biophysics: Biophotonics*. 8 In this important paper, he puts forward in great detail a model that:

accounts at least partially for the experimentally determined properties of a stationary and necrotic [death] photon emission from an intact and irreversibly perturbed (dying) organism, respectively ... (but) where do biophotons come from and where do photons of the necrotic radiation go to? ... Is there any Kingdom of Light, beyond the stars, planets, plants and animals? ... These questions challenge us to enrich our understanding of biophotons and the mystery of life and death ...

Light has been always intrinsically related to the creative power that gives birth to life. Indeed, the cell division, fertilization of an egg and the death of the cell are accompanied by PE [photon emission]. Light is considered as the unitary purposive principle which engenders the Universe [he does not say by whom, but he is presumably referring to some religious traditions and possibly the views of some scientists, especially in light of what he says next about photosynthesis] and that has the nature of first cause. It is an ultimate source of energy on Earth and a driving force of photosynthesis and other photobiological processes ...

Recent findings suggest that biophotons convey hidden information coded in the spatiotemporal parameters of the electromagnetic field, such as a degree of coherence ... Therefore biophoton emission might deliver important information about the onset and the end of life processes ... If necrotic PE [photon emission] appears to be a universal phenomenon ... announcing the end of biological life, then its measurements could be a new criterion of biological death.

This is an interesting suggestion, that clinical death could be measured by this new means. It might avoid mistakes such as people being declared dead on the basis of their breathing having stopped, or their hearts having stopped beating, and then nevertheless they suddenly return to life, occasionally after having been taken to the morgue as a corpse. Sometimes people can 'come back to life' after an astonishing length of time. The novelist Franz Werfel was declared clinically dead in 1943, but then came back to life forty-five minutes later, and recounted an amazingly detailed near-death experience that occurred to him during that time. (He died a second time, staying dead, in 1945.) Perhaps biophoton measurements would provide a new and foolproof method of determining genuine death.

Many people reading about this will be unaware of the astonishing progress made in recent years in understanding aspects of light never previously suspected. Much of this research has been funded by governments and corporations rushing to perfect quantum computing, and some of it can help us understand how the processes involved in the death flash might work.

To take one example, a team of scientists at Stanford University in California as long ago as 2005 (which in this field seems like the age of the dinosaurs) published a paper entitled 'Generation and Manipulation of Nonclassical Light Using Photonic Crystals'. <sup>10</sup> They are talking about cavities inside minute crystals capable of storing photons. At the head of this paper they inform us: 'Photonic crystal cavities can localize light into nanoscale volumes (somewhere between a molecule and a virus) with high quality factors. This permits a strong interaction between light and matter ...' This field is now referred to as nano-photonics because, obviously, it takes place at the nano scale and is hence a branch of nano-technology. These areas of science are certainly underreported.

When considering a burst of light as weak as that of the 'death flash', we need to keep in mind that light can be stored, inside one of these photonic crystals, also called a 'light crystal'. These crystals exist at the upper end of the nano-scale, meaning they are about the size of viruses. In laboratories, light crystals have been fabricated in one, two, and three dimensions. One of the reasons why so much work has been done on this is because people wish to use them to construct 'optical computers', by which is meant computers that employ photons for the purposes of computation.

Turning back to our main concerns, at the nano scale all organisms apparently contain countless 'light cavities', or nano-voids. If we have earlier been puzzling therefore about where the light would have come from that is released in the 'death flash', we have plenty of potential 'light cavities' throughout the body to choose from. Maybe the pineal gland contains one or more, for instance, as it is known to have some unexplained light-sensitivity aspects. The main point is that light storage happens all the time, so the release of a burst of light poses no real logistical difficulty. In other words, the storage of such a body of light would be entirely normal when the organism was alive, and its release at death could be automatic. I am speaking only in general terms, as not enough is known yet to be more specific.

We don't necessarily need to know where a death flash comes from. The Polish scientist Barbara Chwirot published a paper in 1998 with the pertinent title 'Do We Always Need to Know Molecular Origin of Light Emitted by Living Systems?' In this paper she says:

... it is now commonly accepted that both the intensity and the spectrum of the ultraweak luminescence depend strongly on the physiological state of the living systems, on their state of development and on the actions of the external factors, especially those that can be considered the stress factors.

And of course, the ultimate stress factor is death.

Reports of mist arising from a dying person have been reported frequently over the years, and the subject has been mentioned in various scattered publications. But a good place to turn to for some collected evidence is the book *Glimpses of Eternity* by Raymond Moody. <sup>12</sup> In describing the strange mist that appears over the deathbed, Moody says:

They describe it in various ways. Some say that it looks like smoke, while others say it is as subtle as steam. Sometimes it seems to have a human shape. Whatever the case, it usually drifts upward and always disappears fairly quickly.

Moody's book is full of accounts of deathbed experiences and things that people have seen when their loved ones were dying. One man named Tom described watching the death of his mother: 'I saw this film or transparent envelope of light close up and lift off her body going upwards and out of sight.' Moody quotes a medical doctor who told him:

I have seen mist coming up from deceased patients twice in a six-month period ... The mist had depth and complex structure. It seemed to have layers with energetic motion in it, which is a poor description, I know, but just think of something as subtle as water moving within water. <sup>14</sup>

## A hospice psychologist told him:

I saw patients leave their bodies in a cloud form. I saw them rise out of their bodies and head toward these structures. I would describe these clouds as a sort of mist that forms around the head or chest. There seems to be some kind of electricity in it, like an electrical disturbance. <sup>15</sup>

In a 1975 book entitled *Beyond Life's Curtain*, Dr Bernard Laubscher repeats descriptions given by carers sitting beside dying persons in care homes:

While watching at the bedside of the dying one with one or two candles burning, they had seen the formation of a faint vaporous body, an elongated whitish purplish-like cloud; parallel with the dying person and about two feet above the body. Gradually, this cloudlike appearance became denser and took on the form, first vaguely and then more definitely, of the person in the bed. This process continued until the phantom suspended above the body was an absolute replica of the person, especially the face. They noticed that there was a light all around the outline, which I could only compare to a neon tube. <sup>16</sup>

The neuropsychiatrist Dr Peter Fenwick and his wife Elizabeth Fenwick in their 2008 book *The Art of Dying* speak of the 'smoke', 'grey mist', or 'white mist' that leaves the body at death. An informant named Penny Bicliffe told them about what she witnessed when her sister died:

I saw a fast-moving 'Will o' the Wisp' appear to leave her body by the side of her mouth on the right. The shock and beauty of it made me gasp. It appeared like a fluid or a gaseous diamond, pristine, sparkly, and pure, akin to the view from above of an eddy in the clearest pool you can imagine ... It moved rapidly upwards and was gone. <sup>17</sup>

#### Another woman described the death of her husband:

I turned my head to see if Keith was awake, and as I looked I saw a shimmery haze (similar to what you might see above a road on a hot summer day) hover above Keith's sleeping head, and then it gradually rose up to the ceiling and vanished. <sup>18</sup>

# A physician named Dr R.B. Hout was present at the death of his aunt and witnessed the following:

My attention was called to something immediately above the physical body, suspended in the atmosphere about two feet above the bed. At first I could distinguish nothing more than a vague outline of a hazy, fog-like substance. There seemed to be only a mist suspended, motionless. But, as I looked, very gradually there grew into my sight a denser, more solid, condensation of this inexplicable vapour. Then I was astonished to see definite outlines presenting themselves, and soon I saw this fog-like substance was assuming a human form. The features of the face were very similar to the physical face, except that a glow of peace and vigor was expressed instead of age and pain.

The eyes were closed as though in tranquil sleep, and a luminosity appeared to radiate from the spirit body. There was a silver-like substance streaming from the head of the physical body to the head of the spirit body, The colour was a translucent luminous silver radiance. The cord seemed alive with vibrant energy. I could see the pulsations of light stream along the course of it, from the direction of the physical body to the spirit 'double'. With each pulsation the spirit body became more alive and denser, whereas the physical body became quieter and more nearly lifeless.

Hout said that when the pulsations stopped, various strands of the cord snapped. When the last connecting strand snapped, 'the body rose to a

vertical position, the eyes opened, and a smile broke from the face before it vanished from my sight.' 19

A report published on the day of my birth, 25 January 1945, quoted an American soldier back from the Second World War as saying:

'I have seen ectoplasm on the battlefield. I have watched it emanate from a badly wounded soldier and then disappear as that soldier breathed his last.' One hillbilly comrade from Kentucky called it 'soul mist', revealing that many natives in his part of the country considered it quite a normal thing, although they seldom talked about it ... he went on to tell how, after being wounded by shrapnel, another soldier lay badly wounded about ten feet from him.

'I looked at him with pity, forgetting my own pain. Then in the deepening twilight I saw a strange smoke begin to curl above him as though coming from his stomach as he lay on his back moaning ... Then I remembered what my friend had said about soul mist, and I watched fascinated as the ectoplasm became denser and began to flow towards me. For a moment I thought I saw in it the face of a kindly old lady. Presently it reached me and for a second I was bewildered by a strange sensation that came over me. I felt stronger. With my left arm I raised myself and began to crawl to the dying soldier. I reached for my canteen of water. The mist was still around me, and with a sudden effort I was on my feet, and beside the soldier ...

'To my dying day, I shall believe the ectoplasm from the body of that dying soldier had helped me in a mysterious way. It had given me sufficient strength to save my life.'20

And there is not only a 'death flash', there is also a 'death signal' before that. This bizarre finding has so far only been verified at a very small scale, but it is believed to occur in the body as a whole. One of the earlier articles reporting this phenomenon known as 'programmed cell death' (PCD) was written by Michael Otmar Hengartner when he was working at Cold Spring Harbour Laboratory in New York.<sup>21</sup> He is now President of the University of Zurich. He reported that the deaths of cells ('cell deaths') seem to occur as a result of what he called a 'suicide program'. Further study of this strange phenomenon has been primarily done at Stanford University by Professor James E. Ferrell, Junior, and Xianrui Cheng, who is a post-doc colleague of the older Ferrell, who works at the Stanford Cancer Research Laboratory in the School of Medicine.

Ferrell and Cheng's discoveries were first announced in a press release by Hanae Armitage of Stanford, on 9 August 2018, followed the next day by the publication of a key paper by Ferrell and Cheng in *Science* magazine.<sup>22</sup> The press release commences by describing their discoveries like this:

In a cell, death is akin to falling dominoes: One death-inducing molecule activates another, and so on, until the entire cell is shut down, a new Stanford study finds. Inside a cell, death often

occurs like the wave at a baseball game. What starts with two hands flung skyward prompts another, and another, until the wave has rippled far and wide across the whole stadium. This kind of a rolling surge, spurred by the activity of one or a few things, is known as a trigger wave.

A new study out of the Stanford University School of Medicine has found that this phenomenon guides one of the most well-known and widespread forms of cell death: apoptosis. It's not the first time trigger waves have been identified in the microcosms of life. The cell cycle, a cornerstone of cell biology in which cells divide to make new cells, regulates production via trigger waves, too. So do neuronal action potentials, which allow neurons to pass signals via electrical impulse. And it likely doesn't end there.

One really has to congratulate Hanae Armitage, who can a write a press release worthy of a science journal in its own right.

The technical word for cell death, as we have just seen, is apoptosis. Cheng and Ferrell put a lot of effort into researching whether 'the propagation of apoptotic signals' (signals that say 'Die! Die! Die!' to cells) could possibly be chemical diffusion. But they were able to demonstrate that this was all happening by trigger waves, which act in a very peculiar way indeed. If the signals had been by chemical diffusion, they would have slowed down with increasing distance. But the trigger waves did not slow down no matter how far they travelled. In fact, they progressed relentlessly at a constant speed.

They do this by 'positive feedback' in the signal transduction (transmission of signals to cells), which allows 'signals to propagate quickly over large distances without diminishing in strength or speed. We suspect there may be other examples of trigger waves in intra- and intercellular communication.' The steady speeds of the death waves studied by Cheng and Ferrell were 30 micrometres per minute. Because the waves resemble the flows of calcium ions (which had been studied to such an extent by Peter Mitchell, who was mentioned earlier), which are ionic charged currents, we can regard them as genuine plasma flows.

In other words, death appears to take place by plasma signals, which are able to traverse cells without losing any strength or slowing down.

The body is riddled with bio-currents such as 'proton pathways', 'electron pathways', and 'ion pathways' sending signals every which way. I had intended to write a chapter about this, with emphasis on the work of Peter Mitchell, but decided it was not necessary for this book, which contains enough information as it is. One amusing little titbit that I cannot resist mentioning, however, is what R.J.P. Williams said in *Nature* in 1995

about protons moving along proton pathways inside the body: 'Protons move in very short hops (smaller than one angstrom unit) [one tenth of a nanometre] and require rotational movements of many donor and acceptor groups to make the process continuous.'23

I thought the idea of hopping protons was so funny, readers might like to have a good laugh at the thought. However, the death signals travelling at constant speed are evidently not transmitted by hopping protons, but by speedier and more reliable means.

Death signals by photons had previously been detected by the Russian scientist Vlail Petrovich Kaznacheev (aka Kaznacheyev) in a series of more than five thousand experiments carried out at his Institute of Clinical and Experimental Medicine in Novosibirsk in Siberia. In 1976, an English translation of one of his papers appeared discussing the apparent 'paranormal transmission of death' between cells.<sup>24</sup> It included this diagram of the process:

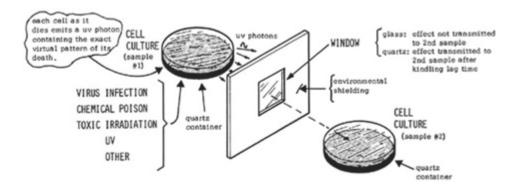

Figure 32. V.P. Kaznacheev's diagram of the process of 'death transmission' between cells, published in 1976 in English. The two dishes contain portions of the same cell culture placed in two separate quartz containers, and the experiment was done in darkness. As each cell in the cell culture at left dies, he says 'it emits an ultraviolet (UV) photon containing the exact virtual pattern of its death'. A shield with a window is set up between the two dishes of cell cultures. The UV rays pass through the window when it is made of quartz, but not when it is made of glass.

This was exactly what Alexander Gurwitsch had discovered about UV rays in the 1920s, which he called 'mitogenetic rays', and which are now called biophotons. Kaznacheev was thus partially replicating Gurwitsch's original experiment, which we saw earlier, concerning the ultraviolet signals passing between onion roots. These were similarly blocked by glass but permitted by quartz. What Kaznacheev discovered by his experiment was that if the cells in the dish on the left were killed by virus infection, chemical poison, toxic radiation, or some other means, death as if by the same means was paranormally transmitted to the cells in the right-hand dish, as long as the UV rays could pass through the window. He found out later that these death messages also can be transmitted in daylight but much more weakly.

It is not only death that has flashes and signals, it is conception as well. When a human egg is fertilized by a sperm, a light flash is seen. This has been filmed, and many people will have seen the various films of this on YouTube. <sup>25</sup> Although the conception flash is 'ultra-weak' in the same way that biophoton emissions are, these flashes too are caused by a wave of calcium ions going through the cell. And calcium ion flow is a form of plasma, just as we have seen in the death waves. It seems that 20 per cent of the egg's zinc is jettisoned upon successful fertilization. Anyone who is interested in this subject should watch the very dramatic moving films of the flashes. Death flashes may not have been filmed yet, but Conception Flashes most definitely have been.

What does all of this mean? We have flashes and signals to do with when physical life begins and when physical life ends. It appears that these are points when our plasma selves activate and deactivate our physical bodies. But what remains constant must be our bioplasma selves. Bioplasma bodies do not 'wear out' through physical wear and tear, it is the physical bodies that do that. Whether bioplasma bodies have other, and non-physical, ways of undergoing any kind of disintegration we do not know, but as it could not be physical, it is likely that it would take the form of an impairment or degrading rather than a total catastrophic collapse.

In recent times the development of new technology has given us vantage points from which to see ourselves and our own intelligence in a new light.

AI (Artificial Intelligence) tends to see intelligence in terms of the transmission and processing of information. When it comes to understanding and defining human intelligence, this perspective leads naturally to a focus on the flow of information rather than in the traditional way, which focused on the flow of chemical and biological processes. This school of thought is sometimes called Information Theory, and we will see what great insights it inspires in the next and final chapter.

Traditional digital computers work by considering simple either/or options and sometimes in the case of very powerful digital computers, an immense accumulation of them – the bigger the accumulation the more powerful the computer. The quantum computers currently in development, on the other hand, work on a wholly different level, because they are able to consider many more options than a simple either/or at any one time, and

make multiple calculations simultaneously. And in this they are, of course, very like the human mind. We are able to consider many options at once, which is perhaps why we have free will – in a way that digital computers do not.

Crucial to the development of how these quantum computers work is the way they use plasma – another instance of plasma acting as a gateway for effects to emerge into the macro world.

Are we now able, from the vantage point created by the development of machine intelligence and quantum computers to look at our own evolution and particularly the evolution of our intelligence, in the light of plasma?

In the next chapter, we will expand our understanding of how universal fields not only influence our consciousness, but also help create it. We will also address the issue of consciousness in the Universe as a whole.

## Our Plasma Selves

Fields contribute not only energy but information too, information that may play a vital role in triggering intelligence both in humans and in plasmas in space.

We now come to what interests everybody the most, ourselves. Is it possible that we are really much more than we think we are? So much more, in fact, that we transcend our physical bodies even while we are 'alive', and after we 'die', we are still very much around, just invisible and somewhat out of touch? There is every reason to think so. I have already made plain how rare physical, or atomic, matter is in our plasma universe. So if we have plasma bodies, it is only to be expected. After all, why should we not have plasma bodies? Most things are made of plasma, so why not us? And in this chapter I will advance this argument by describing some more details of what our plasma bodies may be like.

A very interesting angle is provided by information theory and a parallel school of thought called bioinformation. Information theory was first articulated in 1948, with elaborate mathematical precision, by Claude Elwood Shannon (1916–2001).

Building on the work of nineteenth-century logician George Boole (1815–1864), who realized that logic could be used not only as a closed system, but to solve problems in the real world, and working in parallel with another maths genius, Alan Turing (1912–1954), Shannon realized that intelligent machines could be built out of simple logic junctions with binary yes/no answers. Crucially, he saw how these machines might be used as more than just calculators, but as entities that might act in the real world. We can think of this on the model of a thermostat. If information is fed into

it that the temperature of water, for example, has reached a certain level, then the thermostat will 'act' by switching heat on or off.

This sort of logic junction can in principle be replicated an infinite number of times, primed with different algorithms according to what its engineer wants to achieve. Increasing the information storage and processing capacity of these machines gave rise to the invention of CDs and mobile phones as well as the Voyager space missions, the development of the internet and of Artificial Intelligence.

But more important for our purposes here is that putting information theory into practice by building intelligent machines helped us to reassess what counts as intelligence. We began to see our own intelligence in a new light, less as a series of chemical reactions and more the processing and communication of information. It also became possible to recognize the operation of intelligence in other areas of the Universe, in plants for instance.

In biology, processes such as growth can be seen as occurring when information encoded in the double helix in the form of DNA is communicated at conception.

The roots of 'bioinformation' go back to 1915, when a Russian scientist named Alexander Leonidovich Chizhevsky (aka Chizhevskii, and also aka Tchijevsky, 1897–1964), aged only eighteen, began a systematic study of the relationship between biological phenomena and large-scale cosmic events. By the age of twenty, he was already lecturing at Moscow University as well as at the Moscow Archaeological Institute. From 1922, however, he concentrated entirely on his biophysics work, and by 1940 he had established by experiments that various cosmic and magnetic phenomena had distinct effects on organisms.

Separately, in 1935, a group of Japanese scientists led by M. Takada showed that the rate of human blood clotting was related to solar activity. This was confirmed by later scientists. All such early work relating to electrical and magnetic influences upon the human body had a big effect on another young Russian scientist named Aleksandr Samuilovich Presman (1909–1985), who devoted most of his life and career to following up on it.

In the course of the book we have looked at hints that fields such as the electromagnetic that pervade the Universe might interact with plasma to create the conditions necessary for intelligence to evolve. There interactions

are not simply a matter of energy, but the communication of information, too. This was Presman's whole study.

After many years of work, study and experimentation, in 1968 Presman published a book so stupendous in its summary of experimental findings by himself, his colleagues, and his predecessors, that it can be described as a classic, a milestone, and a fundamental work of reference. His book was published by the Nauka ['Science'] Press of Moscow, and was instantly spotted in the West, so that an English translation was published in 1970 with the title *Electromagnetic Fields and Life*.<sup>1</sup>

A huge amount of meticulous translation and editing went into this translated book, the English of which is flawless (as I mentioned earlier, this is a very unusual feature for translated Russian scientific works). The publication was made possible by special permission of the USSR authorities. Presman was by this time at the Department of Biophysics in the Faculty of Biology of Moscow University and may also well have had special funding from America, which is not specified. The book is 336 pages long and filled with a bewildering, indeed an overwhelming, amount of detailed information. But it is the last 139 pages of the book that were to have such a powerful impact on what matters most to us, for it was in that section that Presman elaborated this concept of bioinformation within the body in such a vivid manner; it became evident that on that evidence alone, there must be such a thing as bioplasma and hence that there must be plasma bodies also.

Presman said that every human body in the upright position was essentially an ellipsoid – a sort of elongated sphere – for purposes of analysis of currents and fields. Here are his drawings showing what he meant:

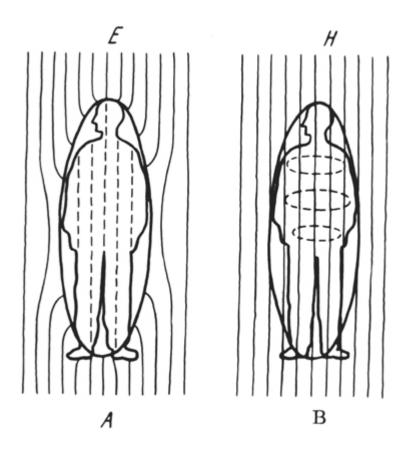

Figure 33. The standing human body is largely composed of electrically conductive water, and acts as an organic antenna, receiving waves and currents from outside and communicating them to the body's interior. It appears standing and therefore as an ellipse for the purposes of Presman's whole-body analyses and studies.

At left the man is standing in a uniform electric field and the dotted lines show the direction of the induced current within the body, which is vertical and hence parallel with the electric field lines. At right, the man is standing in a uniform magnetic field and the dotted lines show the induced current circling within his body is at right angles to the magnetic field lines. (Figure 16 from Presman's book *Electromagnetic Fields and Life*, p. 50.) As we have already seen, electric fields and magnetic fields are always at right angles to one another. For instance, if a current is flowing along a wire, a magnetic field will be created in a circle surrounding it, in other words it expands at right angles to the current.

Presman says: 'The human body is ... a homogenous (in electrical properties) conducting ellipsoid.' And the major axis of the ellipse is the height of the person. (Naturally, there are countless smaller minor currents

and fields within the human body, and this portrays the body only when treated as a whole and surrounded by an external field.)

Shortly I am going to skim through the first portion of Presman's book and give extracts of Presman's comments, stripped of their data and diagrams and equations, so that you can enjoy some vivid glimpses of what he and his colleagues and predecessors had already discovered as early as 1968. Some of what you will read will possibly also horrify you. So, as they say sometimes prior to television broadcasts: sensitive persons might wish to look away now. EmF stands for 'electromagnetic field'.

In the Introduction to his book, Presman calls attention to what his studies have forced upon him in order to make sense of his findings:

This has given rise to the need for a fundamentally new theoretical approach to the problem of the biological activity of EmFs – a theory which will not only be consistent with the experimental data but will provide a basis for their interpretation and an elucidation of the particular mechanisms involved.

The application of this theory to biology has shown that, in addition to energetic interactions, informational interactions play a significant (if not the main) role in biological processes. Such interactions entail the conversion of information, its transmission, coding, and storage. The biological effects due to these interactions do not depend on the amount of energy introduced into the particular system, but on the amount of information introduced into it. The information-carrying signal merely causes the redistribution of the energy of the system itself and regulates the processes occurring in it. If the sensitivity of the receiving systems is sufficiently high, very little energy is required for information transfer ...

It is a valid assumption that all these special features of the reactions of living organisms to EmFs are associated with certain biological systems formed in the process of evolution for the reception of information from the environment. This hypothesis has already received experimental verification.<sup>2</sup>

Information is concerned with tiny bits of information as much as vast amounts. For example, every electron that arrives as a signal is thus a new piece of information, a piece of information not previously possessed.

Presman extended what he stated above, and said that information took precedence also in 'the regulation of physiological processes' within the body, and was crucial for 'informational connections between organisms', by which he means not just signalling between animals but crucially communications between people, whether direct or by distant means.

At this point, we should stop and think again about what is meant here by 'information'. The word is not being used in the traditional sense of 'a collection of facts'. Its use is the more modern and specialized one,

prompted by information theory and relevant to what we now call IT (information technology). And that means that 'information' is being used not solely in the sense of passive information, which is only of use to conscious beings who receive it and make of it what they will, but in the sense of active information, which, when received, triggers an action of some kind, as in the example we saw earlier of the thermostat.

When conceived of in this way, 'information' is another word for 'a signal', or taking it further, as 'an activator', like pulling a switch. All hormones in the bloodstream convey information of this kind, as do our nerves when they sense that the fire is hot and trigger a response of our withdrawing our hands from the hot stove.

Here then are some of the findings of Presman extracted from his lengthy accounts, starting with some important information on the environment in which we live:

In the earth's atmosphere there is an electric field (Ee) in a direction normal to [at right angles to] the Earth's surface so that this surface is negatively charged and the upper atmosphere is positively charged. The strength of this field depends on the geographical latitude ...

Presman realized that he had to try and figure out more about how the body plasma worked and how it received and transmitted information. He made maps of the distribution of surface electrical potential over the body to help him understand what was going on. Here are his maps of the bodies of a lizard and a man:

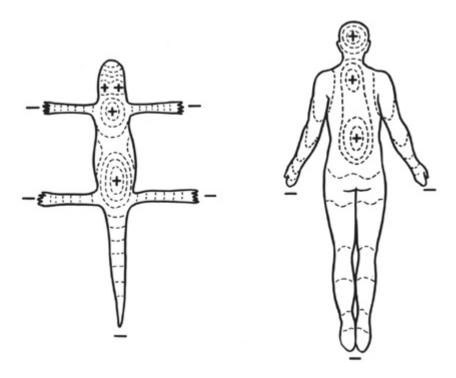

Figure 34. Presman's maps of the distribution of surface electric charge as it occurs on the body of a lizard and the body of a man. (From *Electromagnetic Fields and Life*, p. 237, fig. 93.) Key points for the man are the brain and the spinal cord.

Presman's investigations led him to conclude that DNA molecules are generators of radio-frequency signals and that RNA molecules (one of the four believed to be essential for all forms of life, with a role in coding and decoding genes) are amplifiers of those signals, whereas enzymes and amino acids are effectors of those coded signals. The cell wall he regarded as a noise filter. He believed that at a fundamental level protein synthesis resulted from 'interactions within the organism and its interactions with environmental EmFs'. In other words, electromagnetic fields carry information that activates molecules containing information, which in turn generate signals carrying information, which then trigger life processes within the body.

I cannot emphasize enough that Presman's reconceptualization of biology as orchestrated information flows could not be further from the purely chemical viewpoint. I am aware of how passionately and virulently many biologists hold to their exclusively chemical preconceptions. Through my years of friendship with Peter Mitchell, I heard from him so many times accounts of his twenty-year struggle to overthrow what he called 'the bag of

enzymes school of thought' in biology. Before Peter revolutionized the science, following in the footsteps of Presman, biologists believed that the use of energy in the body was purely chemical. Cells were these 'bags of enzymes' that interacted purely by chemical diffusion.

Peter was able to prove that current flows across membranes were what mattered, and that energy usage had structure and direction — in other words, it transmitted triggering information. And since, as I mentioned earlier, Peter believed that measurements of 'energy' are really records of transactions, his revolution that won him the Nobel Prize was in its underlying premises surprisingly similar to Presman's, though I do not think he had come across Presman's work.

For both Peter and Presman, transactions are essentially information exchange. They viewed bodily signals as the transmission of information. And what Presman concluded was going on was information transmission and reception both within and without every organism by electro-magnetic means.

This brings us closer and closer to the true nature of our plasma selves. In working out the details of this, Presman drew upon the ideas of the Austrian biologist Paul Alfred Weiss (1898–1989), who in turn had drawn heavily upon the ideas of my old friend Joseph Needham (1900–1993) with whom I collaborated on my book *The Genius of China*,<sup>3</sup> and with whom I travelled to China in 1986, the only Western collaborator of his ever to do so.

Weiss was famous for his lengthy book *Principles of Development*. Because of Weiss, Presman was encouraged to ask 'why a free cell, which can extend in so many directions, often advances steadily in one direction to the exclusion of others', and 'how do cells recognize one another?' It was clear to Presman that these were consequences of information transmission within the body. He believed that this was because 'of the existence of diverse interconnections within the living organism by means of EmFs'. And then, having arrived at this view, he turned to the work of Albert Szent-Györgyi for help in figuring out how all this happens. A summary of Szent-Györgyi's ideas has already been given at length in Chapter 14, but the key point here is that Szent-Györgyi viewed the body electronically and insisted that it contained organic semiconductors that modulate and control the current flows and informational signals.

It was at this point that Presman adopted the term bioinformation. He says:

Signals transmitted in the animal world by methods of as yet unknown physical nature have recently been called bioinformation. There are grounds for believing that in several cases such signal transmission is effected by EmFs of various frequency ranges. This is borne out, firstly, by the high sensitivity of animals of the most diverse species to EmFs, and especially by the fact that EmFs can act as ... stimuli for the elaboration of conditioned reflexes. Secondly, it has been found that people exposed to EmFs experience various sensations and that some animals have special EmF receptors. Thirdly, EmFs of various frequencies have been recorded in the vicinity of isolated organs and cells, as well as close to entire organisms.<sup>5</sup>

At this point, I must bring in the entirely separate work on these ideas of my old friend David Bohm, whose ideas we have already encountered in Chapter 14, one of the most brilliant and original scientists of the twentieth century. An American colleague and close friend of Einstein's when Einstein was in exile in America, David then went into exile himself.

I first met David in London in 1982, and in that same year I published the first autobiographical account of him ever to appear, in the *New Scientist* magazine.<sup>6</sup> David was so shy, he had never been profiled before. It took me ages, assisted by his wonderful wife Saral, to persuade him to let me take his photograph. Saral realized that people found the correct spelling of her name confusing, so she often called herself Sarah Bohm. If it were not for her, David would never have survived his many years of bad health and the horrible stress, anxieties, persecution, penury, vilification, and despair that he went through during his lifetime as an exile, dragging himself from country to country trying to find somewhere to come to rest, which ended up being London.

My wife and I later became very close to the Bohms and saw them many times. David was always desperately ill and Saral was afraid he would die at any moment of his terrible heart ailments. I never knew anyone to take as many pills every day as he did. He had a tea trolley entirely covered with boxes of different pills, and had to rootle through them to find the right ones, which he did while discussing quantum theory.

As a young American scientist, David had been enjoying the prospects of an excellent academic career at Princeton University, where he was a colleague of Albert Einstein, who admired David a great deal. During the war, David Bohm conducted research into plasma. When he saw the movement of particles in plasma, it struck him that they were behaving in concert in the way living creatures do. It seemed to him that there must be some underlying field or dimension that was interacting with these particles, resulting in life and a form of intelligence.

This vision of intelligence in plasma became a paradigm for David Bohm as he developed a scientific and philosophical account of the Universe that made him a senior figure in the second wave of theoretical physicists in the quantum revolution.

In 1951, he published what many still consider the finest existing textbook on the standard interpretations of quantum theory. But then politics intervened. David's PhD supervisor had been Robert Oppenheimer, who came under political investigation by Congress for possibly being a communist. David was not himself a communist (although he was certainly very left wing), and he did not want to be called before the Congressional Committee to testify against his former supervisor. So he fled America and settled in Brazil. That was the beginning of the rest of his life in exile, with some years spent also in Israel (he and his wife were both Jewish, though non-practising). 8

It was David Bohm who moved the concept of 'information' forward into a whole new dimension. From the 1980s until his death on 27 October 1992, David continued to elaborate the most revolutionary ideas on this subject. As we have seen, Presman was concerned with biology and biophysics, whereas David was concerned with physics and mind. The key to David's innovation is in his own elaborate and individual concept of active information. Earlier I spoke generally of passive and active information, but that was from my own limited point of view, based upon what seemed to me common sense. It is now time to see what a real scientific genius does when he gets his hands on the idea of active information.

Let us start with this startling remark by David's protégé in this particular field, the Finnish philosopher of science, Paavo Pylkkänen. He says that, according to David Bohm '... not only the behaviour but also the very being of particles [are] based on the activity of information.'9

That is a very big claim. It puts active information at the heart of everything.

David's alternative interpretation of quantum theory is often famously known as the causal interpretation. In the classic formulation of quantum mechanics, the interactions of waves and particles have uncertain outcomes. The position and other qualities of particles can therefore only be expressed in terms of probability rather than of certainty. It was thought in the standard view that this will always and inevitably be the case, because it reflects the way the Universe is made.

Albert Einstein was sceptical of this and so was David Bohm. In his formulation, cause and effect holds true in the quantum world as it does in the macro or everyday world, but we cannot calculate results with certainty because we don't have all the information. There are 'hidden variables', and he saw these as being hidden in the information contained in the waves, as the form of a signal. He stressed that form, having very little energy, enters into and directs a much greater energy. It puts form into it, i.e., it informs it; hence, inform-ation. In other words, uncertainty is not a quality of the physical universe. It only arises because we don't have enough information.

David Bohm's interpretation of quantum mechanics, based upon what he called 'hidden variables', is perfectly valid in terms of all experimental results, and the difference between it and the standard view is a difference of interpretation. He first published it in January of 1952, in a series of two papers in the *Physical Review*. Those papers had a big impact upon Louis de Broglie (1892–1987, Nobel Prize for Physics 1929) in France, as a result of which de Broglie also abandoned the 'standard' interpretation of quantum mechanics, with tremendous repercussions in the world physics community, and which greatly added to David's scientific status. <sup>11</sup>

So David's focus on information as the driving force at the heart of the Universe helped throw a startling new light on the central problem of quantum mechanics, which has been a matter of debate and generated a spectrum of views over the last hundred years. To explore further the mindbending ideas of David Bohm, it is helpful to start by contemplating how a small energy charge can, by the transmission of information, trigger wholesale changes in an entity with much larger energies. Here are some comments he made in a 1987 book:

The basic idea of active information is that a form, having very little energy, enters into and directs a much greater energy. <sup>12</sup> This notion of an original energy acting to 'inform', or put form into, a much larger energy has significant applications in many areas beyond quantum theory.

Consider a radio wave, whose form carries a signal – the voice of an announcer, for example. The energy of the sound that is heard from the radio does not in fact come from this wave, but from the batteries or the power plug. This latter energy is essentially 'unformed', but takes up its form from the information within the radio wave. This information is potentially active everywhere, but only actually active when its form enters into the electrical energy of the radio.

The analogy with the causal interpretation [of quantum mechanics] is clear. A quantum wave carries 'information' and is therefore potentially active everywhere, but it is actually active only when and where this energy enters into the energy of the particle. But this implies that an electron, or any other elementary particle, has a complex and subtle inner structure that is at least comparable with that of a radio ... nature may be far more subtle and strange than was previously thought. <sup>13</sup>

A lot of the force of his thinking comes from his focus on what we don't know rather than what we do. He uses his colossal mathematical and scientific imagination to map new territories. Here David is saying that events in the Universe, including at the quantum level, unfold in the way they do because of an exchange of information between fields and particles that may contain a lot of information and mechanisms, which at the moment we have little idea about. In fact, we can scarcely begin to dream about them.

In 1979, the twenty-year-old Finnish undergraduate student at the University of Uppsala in Sweden named Paavo Pylkkänen (quoted above) became interested in David Bohm's ideas. The following year, he was able to meet him at a conference in England. Throughout the early 1980s, Pylkkänen encountered David at other conferences and then in 1984–1985, when he commenced a Masters' thesis at the University of Sussex, he was able to meet and discuss David's ideas with him in greater detail. In 1988, Pylkkänen commenced a PhD course at the University of Helsinki, with the subject being David's interpretation of quantum mechanics and its potential importance for cognitive science (that is, how we think).

In 1990, with grants from Finland, he was able to become 'an academic visitor' at both Oxford and David's own Birkbeck College of the University of London. This made it possible for him to have plenty of conversations with David and with David's closest collaborator and academic friend, Basil Hiley, who was also at Birkbeck. This period coincided with David's publication in 1990 of a brief but essentially final version of his ideas about

how his version of quantum theory related to the functioning of the human mind. 14

Pylkkänen was thus very much in the right place at the right time. In July of 1992, Pylkkänen completed his thesis and submitted it to the University of Helsinki, only three months before David's death. If David had lived longer, they would probably have written a book together.

Pylkkänen's thesis was published in 1992 by the University of Helsinki. His abstract at the beginning of the book commences like this:

The first aim of this study is to analyse, evaluate, and extend David Bohm's (1990) theory of the relation of mind and matter, based upon his ontological interpretation of quantum theory. [Note: Ontology is a branch of metaphysics dealing with the nature of being. In Bohm's interpretation, uncertainty arises as a problem of perception, not a problem with the nature of reality or being.] The second aim is to consider the relevance of this theory to the philosophy of cognitive science.

This interpretation postulates that elementary particles are guided by a field containing active information. Bohm suggests that in certain key ways the activity of information at the quantum level is similar to the activity of information in ordinary human subjective experience, and he uses this similarity as a basis for his mind-matter theory.

What Pylkkänen is pointing to here is that Bohm sees some of the bizarre behaviour described in quantum mechanics in the common human experience of consciousness. This is important for the main theme of this book because, as we have already noted, human brains (like quantum computers) contain complex plasma, and plasma may be a medium by which uncertain and bizarre quantum phenomena enter the human experience.

In 2006, Pylkkänen published an ambitious book entitled *Mind, Matter and the Implicate Order*.<sup>16</sup> The 'implicate order' is the phrase that had been used by Bohm for decades to describe aspects of his evolving theories to do with the self-ordering qualities of the Universe, analogous in some ways to Prigogine's ideas of dissipation, which we looked at in Chapter 3. This book carries forward all his thoughts on David's ideas, and his Preface commences like this:

I have been planning to write a book ever since I finished my PhD dissertation ... in 1992. For various reasons it has taken me a long time to do this. I started writing notes in February 2000 ... This book deals with topics that have been variously neglected and even 'forbidden' in academic circles during much of the twentieth century. One such issue is conscious experience, the study of which was famously suppressed in behaviourist psychology and even in traditional

cognitive science, and has only recently become the focus of intense research in a number of fields ...

Yet another traditionally 'forbidden' topic to be discussed in this book is connected with physics and has to do with the interpretation of quantum theory. To some extent, the suppression of discussion about the meaning of quantum theory is connected with the above-mentioned suppression of metaphysics in general, for quantum theory was initially interpreted in the 1920s in the strongly anti-metaphysical climate of logical positivism ... making it 'forbidden' to try to sketch the nature of reality at the quantum level ...

I have chosen in this book to focus ... strongly upon David Bohm's views. For it seems to me that Bohm was one of the few twentieth-century thinkers who had a good grasp of not only quantum physics (which was his original field of expertise and which he indeed helped to develop), but also the natural sciences more generally, as well as philosophy and consciousness. He saw the importance of trying to understand the connections between these areas and was indeed developing a new 'big picture' ...

Pylkkänen is thus very much the heir to David's ideas linking quantum theory with the workings of the human mind. And again central to those ideas is David's concept of active information

Let us get down to greater detail of what the active information theory of David Bohm really suggests in relation to quantum mechanics, and why it is vital for the purposes of this book. Pylkkänen says that David and his colleague Basil Hiley in a joint publication had made:

... a radical suggestion: the quantum field contains something at least analogous to information. Remember that this is information for the electron, not information for us. Information is seen as an objective aspect of reality and it is thought to be generally active ... the first reason to postulate active information at the quantum level is that the effect of the quantum field upon the particle field depends only on the form of the field (the information encoded within it), not upon its amplitude. [Amplitude for a wave is the height of the wave in one ripple, from the bottom to the top of the wave, which scientists ponderously call 'a measure of its change over a single period'.]

The form of the field informs [that is, directs the particle by means of the information it provides] the energy and movement of the particle. This is analogous to the way the form of the radar wave informs the energy and movement of a ship on automatic pilot, the way the form of the DNA informs the activities in a cell and the way the form of a shadow in a dark night can give form to the physiological state of a person who perceives and interprets it [by getting scared]. <sup>17</sup>

In other words, David Bohm is arguing that there is crucial information hidden not only in individual particles but also in fields – and that the entire Universe is triggered by the interaction between them.

To put it another way, a particle such as an electron contains a lot of information, some of which is triggered into action when the particle interacts with an underlying field. Of course, scientists already knew that

the behaviour of particles is changed by interactions with underlying fields, but Bohm's supreme mathematical imagination enabled him to suppose that large amounts of information in a simple seeming particle might interact not only with the fields we already know about, but also with another as yet unknown field, another dimension, something that might even be a cosmic intelligence beneath the fields we know about and ordering them. He called this the Implicate Order and he believed and described in the language of science how the Explicate Order, the Universe we see and experience with our senses, could unfold out of the Implicate one.

He understood this unfolding process to work like a hologram, a way of looking at the Universe he shared with his friend and colleague Karl Pribram, whose work we touched on earlier. A hologram is a record of what an object looks like at every angle. In technology we are all familiar with holograms on bank notes and credit cards. They are made up of light beams, which have been organized to act in concert and deflect off the object that is to be depicted, in order to generate information on what it looks like. The same pattern of beams can then be reproduced to create a 3D image of the object even when it isn't there.

An important part of this analogy for our purposes is that if you break a hologram into bits, each bit will contain an image of the entire object. What David Bohm is saying is not only that the entire universe is a hologram, in the sense of being an unfolding of an intelligent 'implicate order' that underlies everything, but that this driving, ordering process is equally present everywhere in the Universe. It underlies our intelligence, the intelligence we see in animals and plants, and the intelligence we saw in the movements of plasma near the start of his scientific journey, which we are now beginning to understand.

David's focus on the information – rather than the energy – that fields transmit by means of their form brings us to the subject of the work of Rupert Sheldrake. I first met Rupert in 1981, and he and I have been friends now for four decades, as well as my wife Olivia and myself also being family friends of the Sheldrakes (we knew Rupert's wife Jill Purce for more than a decade before we knew him, and their two sons are just as much our friends as their parents are). Rupert and I both knew David Bohm from the early 1980s, but we did not mention it to each other during David's lifetime, and only discovered it later.

Rupert and David were very active together in helping one another with their respective ideas during the years they knew each other, and they took part in conferences together, none of which I attended, alas, as I was very distracted during that period with my work on the history of Chinese science, as a colleague of Joseph Needham. Rupert has published so many books and papers that he is widely known, and it would be impertinent of me to try to summarize his brilliant findings in the field that he calls morphic resonance, which is based upon 'form fields'.

Rupert's background was as a biologist, not as a physicist, and he has told me he does not go in for attempting to formulate physics theories. He had hoped that David Bohm could provide the physics basis to explain morphic resonance, but David was unable to do so, despite the good will between them. There is no doubt in my mind that Rupert's work on the transmission of form by 'morphic fields' is connected somehow with Bohm's transmission of form by 'the form of the field' as mentioned a moment ago. And both are involved in the communication of information as form. Rupert's book *The Science Delusion* (known in America as *Science Set Free*, 2012) is a brilliant analysis of what is wrong with 'mainstream' science, as the ultra-conservatives of science like to call themselves. <sup>18</sup>

An interesting description of the invisible soul was given by the French philosopher René Descartes (1596–1650), who called it *une chose qui pense*, which the English philosopher of science Joseph Glanvill (1636–1680) translated as 'a thinking substance'. <sup>19</sup> This excellent turn of phrase from the seventeenth century is well worth hanging on to. For if I were to find one phrase that I believe sums up the nature of our plasma bodies, as well as the Kordylewski Clouds themselves, it would be to say that those information-laden entities must truly be a thinking substance.

If all entities are essentially plasma entities that from time to time 'become physical', or 'become embodied in atomic matter', then the thinking substance of each entity will have certain information requirements for survival, and these will vary considerably. There are two extreme cases one can mention. The first is moths, which have the ability to detect a single molecule in the air and trace it back to its flower. A more familiar example is to be found in predatory birds such as hawks and falcons. The fantastic eyesight of these birds enables them to spot tiny rodents such as mice from

extreme altitudes, upon which they then suddenly swoop. The visual acuity of these birds is Nature's rival to modern military satellites, which we are anecdotally informed (and it may even be true) can read a car licence plate from several miles above us.

All of these phenomena display the extremes of information-capture. And sometimes information-capture can occur by paranormal means without even trying, when the desperation of the situation is sufficiently intense. I shall give one example from my own life. During my time as a consultant at board level to the telecoms company Cable & Wireless, my wife Olivia and I and our aged dog Kim, a border collie, shared an office at C&W. Kim lay on her silk eiderdown at Olivia's feet beneath her desk. Animals were supposed to be banned from entry in C&W buildings, and Kim was the only canine intruder who ever evaded this prohibition. But one day a grumpy executive made an official complaint about there being a dog in the lift with him.

The matter was judged to be so serious that it was entered onto the agenda of the next board meeting of the Directors of Cable & Wireless. (Yes, this is true.) The director with whom I was associated was Jonathan Solomon, who unknown to the other directors had written a book about his dog who had died, but whom he had loved beyond all measure. When they reached the item on the agenda where the fate of Kim was to be discussed, Jonathan made an impassioned speech to the board that 'doggies are important', to quote his own words, and the board agreed to permit Kim privileged entry to the building as a result.

This matter of great weight and importance, treated at the same level as corporate acquisitions in Asia and the Caribbean, enabled Kim to remain at Olivia's feet, which was all Kim desired. We at that time had the entire top floor of an office building to ourselves, where we played boules and Kim chased the balls. That floor now holds the executive office of Len McCluskey, the head of the Unite Union, who is doubtless too busy to play boules.

One day we had to use a small closed room protected by a door code, and Kim came with us, as her advice was always needed. The door had been opened for us and the person had left. Olivia and I left the room briefly for some reason and the door closed behind us, leaving Kim locked in the room. Kim by then had very serious kidney issues and needed to drink lots

of water, and her bowl was dry. We were told the only person with the door code might not be back until the next day. We knew that Kim could not live that long without water. No one was prepared to arrange for the door to be forced.

In a moment of intense emotion about the fate of our precious Kim, I forced myself to 'know' the door code, which came into my mind in some manner unknown. I punched it in and the door opened, and we were able to save Kim. This is an example from personal experience of the accessibility of information when truly needed, from a world that is probably entirely constituted of information.<sup>20</sup>

As this book draws near its close, I want to mention a peculiarity about himself recorded in his autobiography by Nikola Tesla. He records this:

In my boyhood I suffered from a peculiar affliction due to the appearance of images, often accompanied by strong flashes of light, which marred the sight of real objects and interfered with my thought and action ... I was about twelve years old when I first succeeded in banishing an image from my vision by wilful effort, but I never had any control over the flashes of light to which I have referred. They were, perhaps, my strangest experience and inexplicable. They usually occurred when I found myself in a dangerous or distressing situation, or when I was greatly exhilarated. In some instances I have seen all the air around me filled with tongues of living flame. Their intensity, instead of diminishing, increased with time and seemingly attained a maximum when I was about twenty-five years old.

While in Paris, in 1883, a prominent French manufacturer sent me an invitation to a shooting expedition which I accepted. I had been long confined to the factory and the fresh air had a wonderfully invigorating effect on me. On my return to the city that night, I felt a positive sensation that my brain had caught fire. I saw a light as though a small sun was located in it and I passed the whole night applying cold compressions to my tortured head. Finally the flashes diminished in frequency and force, but it took more than three weeks before they wholly subsided ... These luminous phenomena still manifest themselves from time to time, as when a new idea opening up possibilities strikes me ... <sup>21</sup>

Here we find extraordinarily frank descriptions by Tesla of his being tormented over the years by what appear to be the visualisation and perception of his own plasma body. Our plasma bodies would necessarily be like 'tongues of living flame' surrounding us, because that is what plasma is like. By flames we should not, however, imagine flames producing heat, as with the flames of a physical fire. Notice that Tesla speaks of 'living flame', suggesting that he could see pulsations or waves within the flames, so that they appeared as if they were dynamic and 'alive' in some sense.

It is interesting that he sensed 'a small sun' within his brain. The interaction between a plasma body and a physical body would be expected to involve a node of concentrated plasma somewhere within the brain. I cannot resist the impression that Tesla experienced phenomena caused by his physical body being insufficiently insulated from his plasma body, so that he was tormented by overexposure to it. But that, of course, may explain his amazing mental powers of visualisation, invention, and inspiration.

In other words, perhaps great geniuses have an increased access to their plasma selves. Certainly psychics are always complaining of the agonies they suffer from their paranormal perceptions. Physical suffering thus seems to go with 'plasmic phenomena' invading the physical. This is not at all surprising, because of the higher energies involved. This could explain feeling 'a positive sensation that my brain had caught fire'.

It may well be that many of the great geniuses whose stories we have told in this history had a particularly intense relationship with their plasma bodies and that this is what made them visionaries.

To return to the Kordylewski Clouds, Benjamin Schumacher and a colleague named Michael Westmoreland published an important book in 2010 entitled *Quantum Processes*, *Systems*, *and Information*. They attempt to define information at the beginning of that book like this:

Information is the ability to distinguish reliably between possible alternatives.<sup>22</sup>

As their book moves along, they refine this definition, a journey too detailed for us to follow here, but I would not like people to think this initial statement is where they stop, rather it is where they begin. The authors elucidate information processing at the nanometre scale, and as we will recall, the charged dust particles largely constituting the Kordylewski Clouds are nano-sized. Second, they discuss the complexity of systems needed to generate intelligence, which resonates well with the description by the eminent astrophysicist Wickramasinghe and myself outlined in Chapter 12. Summarizing their findings they say:

We have demonstrated the connection between a complex hierarchical structure and the complex dynamics of the system. The number of hierarchical levels of the system (in our case five) is a measure for the 'homogenous' complexity of the system. The minimum number of

hierarchical levels is a prerequisite in order to realize multi-stability, preparation, measurement, and control, necessary to achieve a complex dynamics which is equivalent to information processing.

Several experts in the new physics of information have made timely comments, which may make claims that everything is essentially information seem less shocking. In 1990, an expert in this field named Wojciech H. Zurek (*zurek* being a favourite Polish soup of mine as well as a common Polish surname) edited a volume of Proceedings of an important conference held the year before. He prefaced it with the sentence: 'The spectre of information is haunting science.'<sup>23</sup>

Two joint contributors to the Zurek volume were Werner G. Teich and Günter Mahler. They gave special attention to 'information processing systems where the basic elements have a dimension of a few nanometres ... (and) possible realizations in form of semiconductor heterostructures ("quantum-dots") as well.' They say that their research might be described as molecular electronics.<sup>24</sup> We may be forgiven for feeling a sense of déjà vu here, because this takes us back to our old friend Albert Szent-Györgyi, who was discussed at length in Chapter 14, and his – you remember correctly – molecular electronics first discussed in a book of his as early as 1957, forty-one years before Teich and Mahler's paper was delivered.

One more paper in the Zurek volume is important for us as well, namely that by Seth Lloyd, who I gather from Google nowadays quaintly describes himself as 'a quantum mechanic'. It is good to know that he can repair nano-sized carburettors and change the spark plugs inside electronic molecules. But what I like most about him is his paper 'Valuable Information' in the Zurek volume. He begins to tell us about the birds and the bees, but in fact the bees are enough:

Information is the currency of nature. A bee carries genetic information contained in pollen to a flower, which in turn supplies the bee with ordered energy in the form of sugar, a transaction that redounds to their mutual advantage ... a drop of sugar sitting by a pistil [in a flower] registers an amount of information equal to the free energy of the drop divided by the ambient temperature: the drop's information is proportional to its calorie content. When the bee gets sugar water in return for DNA, she is getting a very good deal in food value – pollen is low calorie stuff. But the flower is not getting the worst of the bargain.

Although the DNA the flower gains is a diet item compared with the sugar water given up, the information that it contains is of high quality, refined by natural selection through generations, and essential to the flower's ability to reproduce. As a result, the flower places a higher value on the small amount of information in the pollen than on the large amount of

information in the sugar. Value depends not only on the amount of information, but on how difficult that information was to produce.

Down the years, far greater resources have gone into producing flower DNA than the sunlight and soil that went into making today's drop of sugar water. A process such as evolution consists of many interactions and exchanges of information, and the genetic make-up of a species contains, in edited form, information about past interactions between species and environment: genetic information registers experience. '25

The scientists concerned with this information theory stress the need for multiple hierarchies of information. The Kordylewski Clouds are capable of intelligence because they are not just simple plasmas, but are dusty complex plasmas. Their interiors are so complex that they can have a number of hierarchical levels limited only by the size of the cloud. (And since the clouds are so gigantic, there could be many millions, or even billions, of hierarchical levels inside them.)

Earlier we talked about voids in complex dusty plasmas such as the Kordylewski Clouds and their role in separating out different 'organs' with distinct functions within the living entity. I want to mention here some revolutionary work on voids, which suggests that voids may have other, more mysterious functions.

In my earlier book *Netherworld*,<sup>26</sup> (known in the USA in a new title bestowed by the publisher there as *Oracles of the Dead*), I discussed at very great length the importance of voids, stressing that the founding father of void studies was the crystallographer Victor Goldschmidt. It was he who identified the crucial importance of voids in otherwise 'solid' physical matter. He discovered that there was such a thing as systematic and highly geometrical void formation in crystals. The voids were very carefully and meticulously formed, and were not at all random. He called these carefully crafted voids 'dissolution forms'. When a dissolution form reaches complete emptiness, it is called the end-body. These voids were found to form 'void lattices', which were the 'empty' equivalents of solid lattices.

## As I summarized it:

In other words, with the end-body one reaches the final form of the void lattice, and further action by the solvent merely reduces it in size, but no longer alters its conformation. One has attained the pure void form, or we could call it the substance lattice, traced and outlined by some remaining residues of matter, and which is the yin corresponding to the yang of the material shape. <sup>27</sup>

I cannot repeat here the discussion of void lattices and their crucial importance in both metallurgy and in geology, nor can I elaborate further on Goldschmidt's revolutionary work. But these voids and void lattices are so important in general, because they are manifestations of renewal. They are the destruction-lattices that empty themselves of matter so that the new can be made, as the creation-lattices exhaust themselves and come to the ends of their useful lives. In other words, forms grow and die and are replaced anew from formed emptiness that has grown geometrically and sits waiting to be filled. One is the summer and one is the winter, and rebirth takes place from ordered death in an endless process of birth, death, replacement, and renewal. Without the formation of the voids, this cycle cannot happen.

Since voids form in matter, and plasma is made of matter (just not atomic matter), we can expect that plasma clouds will be riddled with voids. This would certainly apply to the Kordylewski Clouds. These voids would serve the function of assisting in the continual regeneration of the clouds, by replacing exhausted lattices in the plasma crystals and renewing the crystals in an endless progression. Indeed, I wonder if the people working on fusion reactors have ever given any thought to facilitating void formation in their plasmas, which might help in their frustrating search (that has already lasted many decades) for a fusion reactor that works.

They won't get anywhere with a uniform plasma. They have to create voids. Presumably pulsations and harmonic resonance could be employed. The other thing, which I mentioned in Chapter 3, is the need for spaces between things, and voids clearly contribute to that. Empty spaces are needed in any large entity. Something that is completely full cannot work. There always has to be some flexibility

The first observation of a void within plasma appears to have taken place in a laboratory in 1996, as reported by G. Praburam and John A. Goree. By 1999, several papers appeared that had studied these plasma dust voids. One by Vadim Tsytovich, Sergey Vladimirov and Gregor Morfill proved that the size of the void depends upon the power input into the plasma, and that the greater the power, the larger the void.<sup>28</sup> Goree and Dmitry Samsonov followed with their own paper that year, as did Gregor Morfill, Hubertus Thomas and other leading scientists. So one could say that 1999 was 'the year of the plasma void'.

Subsequent research was relentless after that, and essentially came to a climax under the direction of the brilliant Japanese scientist Osamu Ishihara, who published the above figure. <sup>29</sup> In this paper, written jointly by Ishihara with his colleague Noriyoshi Sato, they said: 'A void structure, characterized by a dust-free ordered state with a sharp boundary in a dusty plasma, was observed in microgravity conditions [in space orbit] as well as in ground-based laboratory plasmas ... Voids have been observed not only in a complex plasma, but also in colloidal suspensions ... In conclusion, the electrostatic attractive force between like charges in a complex plasma, where charged macroparticles are embedded in a fully ionized plasma, is shown to be responsible for the sharp boundary formation associated with a void ...'

It is interesting to examine how all of this research came to be carried out, especially in light of these comments made by Ishihara in 2008:

Professor Oleg Petrov and Dr Sergey Antipov of Joint Institute for High Temperatures of the Russian Academy of Sciences (former Institute for High Energy Densities, Russian Academy of Sciences), Moscow, Russia, visited our lab [in Japan] from December 22 to 23 2007. We exchanged the detailed information on the experiments of cryogenic complex plasma experiments. We are the only two groups in the world to carry on the cryogenic complex plasma experiments. 30

Another important development is the report published in August of 2021 in *Nature* that at last a material has been discovered that is a natural 'topological superfluid'.<sup>31</sup> The implications of this are enormous, and an entire new area has now opened up that relates to our concerns. If only it were possible to discuss this further.

But these matters go way beyond what we have space to consider here. In the final chapter, we will bring together the arguments to show that plasma in space may well have evolved intelligence billions of years before the evolution of humans.

## Wrapping up the Universe

As we wrap up the Universe we will consider how parts of the Universe seem to be self-organizing, how complex structures emerge, and how the way things slow down and fall apart – the Second Law of Thermodynamics – is by no means the whole story. Highly unstable charged entities such as dusty plasmas throw out dissipative structures over vast distances. In other words, leading scientists have been looking at the way that there are fundamental tendencies in the Universe towards greater and greater complexity – towards the high levels of complexity necessary for intelligence.

In trying to understand how human consciousness and intelligence works, classical science has tended to concentrate on chemical reactions in the brain. In the second half of the twentieth century, many leading scientists shifted the focus to an interaction between matter and subatomic matter in the brain and external fields, such as electromagnetic fields. It is well established, for example, that birds follow migratory paths by interacting with the Earth's magnetic fields. Could this be one small example of a universal phenomenon?

It is also well established that artificial electromagnetic fields from phone masts can have a deleterious effect on human health and behaviour. But could natural electromagnetism on the Earth and more widely in the cosmos have a much more fundamental, indeed essential role in forming and informing animal and human minds? Plasma's unique sensitivity to fields would seem to make it uniquely suited to this kind of interaction. And we have already begun to question whether there is plasma in the brain.

Similarly in recent times the creation of artificial intelligence and quantum computers have helped prompt new perspectives on human intelligence and mind in two main ways. AI tends to see intelligence in terms of the transmission and processing of information. When it comes to understanding and defining human intelligence, this leads naturally to a focus on the flow of information rather than the flow of chemical and biological processes (information theory). Unlike traditional digital computers, which work by considering simple either/or options, albeit an immense accumulation of them – the bigger the accumulation, the more powerful the computer – the new quantum computers work much more powerfully, indeed on a whole different level, because they are able to consider many more options than a simple either/or at any one time, and indeed make multiple considerations such as these simultaneously.

(It seems not to have been recognized yet that this operates by means of what I call 'informational void creation'. When one alternative is chosen over another, this creates an information void in the form of the rejected alternative. However, that void can be filled again by shifting one's choice to that alternative. With multiple choices taking place, the traditional 'one' and 'zero' of normal computing can be replaced by 'empty' and 'full' as concepts, with shifting but parallel geometries of information lattices and information void lattices side by side, continuously changing, the dynamics of these parallel lattices being plotted and manipulated by non-linear equations. This can be studied in reduced form by plotting the mechanisms of memory retrieval. This may sound simplistic, but it is actually the best basis for the construction of a geometry of alternatives in the theory of quantum computing. Someone needs to mathematize it.)

And in this they are, of course. very like the human mind. What makes the development of these new quantum computers work is the way they use plasma – so again we come back to this new way of trying to understand human intelligence and consciousness. Could it be that plasma in the human brain, the human body, has played a vital part in its evolution?

We have seen a great deal of information and learned the life stories of some of the great heroes of science who have brought us this far, despite the fact that many of them were called crazy before they won their Nobel Prizes. Let us now try to bring together a summary of what all of this means.

The first and most important thing is what I have stressed since the very beginning of this book, namely that physical matter is very rare in the

Universe and is not the predominant component of what exists. The obvious conclusion is that if the Universe is full of life forms, including intelligent ones, the majority of them will not be made of physical matter. They will instead be made of plasma. And that may include us. I am suggesting that we are all made of plasma, and that our physical bodies are temporary vehicles for us to operate in the physical world for the short periods of time that our fragile bodies can permit, considering how quickly they wear out, how prone they are to accidents, and how vulnerable they are to disease.

But that has been made amply clear at an earlier stage of this book. What we need to do here is to explore more thoroughly how living entities can come to be in a plasma universe. We are so used to being immersed in a world of physical matter that it is a great struggle for us to free ourselves from the encumbrances of stuff. 'Stuff' is a wonderful word used mostly in America to refer to anything that encumbers one, or gets in the way. On the other hand, 'stuff' can sometimes be useful. It is because 'stuff' has no actual definition that it can be used so readily as an idea.

So let us free ourselves from our physical 'stuff' and let our minds roam free.

It is unavoidable to conclude that if the Universe is made of 99.9 per cent plasma, then life forms in it must also be 99.9 per cent made of plasma. So we need to understand such life forms urgently.

It is indeed difficult for us, being what we are (or should I say, being what we think we are) to imagine that a diffuse charged dusty plasma cloud could possibly be a living being. But what if you were such a cloud and saw us? You might think: 'what thick, clumsy, awkward objects those things are that move upon the Earth! I wonder if they could possibly contain any elements of life in them. They may simply be moving lumps of protoplasm with four protrusions sticking out like viruses have, and everyone knows that viruses are not alive'.

Everything depends upon dust. This sounds so inglorious that it is difficult to grasp, because we are used to thinking of house dust and the need to clean the house, and also in my case to dust my books. But in order for a plasma to come alive, it needs dust. It gives the particles something to cling onto. Ten thousand electrons can cling to a single dust particle. So when you consider how many dust particles there are in a dusty plasma cloud, and if you imagine 10,000 electrons attached to each one, giving

each dust particle the electric charge of 10,000 electrons, gigantic electric charges beyond any power station or power network on Earth can gather in a single cloud. The huge electromagnetic forces of the clouds are inconceivable to our tiny little minds, and even the bravest equation trembles at the thought of the number of exponents appearing in it, each one carrying so many zeroes, it is enough to make a person faint.

So we get it: things are different in space.

One key to all these clouds coming alive is also in the supply of ready food. For plasma entities, that means a reliable flow of particles. Plasma clouds eat particles, in the way that whales eat plankton. Please note that whales are the largest mammals on Earth, but they eat the smallest food. Plasma clouds may be huge, but they too can eat their own 'space plankton', namely charged particles and ions.

And it so happens that suns and stars are, as the English say, 'just the ticket'. For they are spewing out particles continuously, and one aspect of this has been known for a very long time. I am referring to sunlight as the source of energy for plants. If plants can eat sunlight, then why can't plasma clouds do so too? Of course, I am not suggesting chlorophyll in plasma clouds, I am suggesting the absorption of energy from the particles consisting of the solar wind.

The huge electromagnetic forces in the charged clouds are so much more powerful than gravity that they suffice to hold everything together, even if the cloud is extremely diffuse. We must never forget that electromagnetic forces are more powerful than gravitational ones by a factor of 10 followed by 39 zeroes. We should therefore never underestimate the power of electromagnetism to hold things together, a perpetual embrace.

Now we can see that it is not difficult to conceive of these large, charged, dusty plasma clouds becoming things.

How do they become living things?

We have examined the anatomy of complex dusty plasma. At this point I would like to refer the reader back to what I wrote in Chapter 12 about how the 'electromagnetic strength' of the Kordylewski Clouds could arise, which holds them together. I explained how spinning dust grains like incredibly small rice grains (which range in size between a micrometre, which is one millionth of a metre, and a nanometre, which is one thousand times smaller than that), each with a north pole and a south pole, can

collectively by their spinning generate gigantic amounts of energy. They are like billions upon billions of microscopic power generators. And it is these that generate the energy which creates the structure and internal organization of the cloud.

We have seen they do in fact become filled with crystalline structures like the structures in organic life, double helixes capable of storing information, filaments to conduct currents like nerves in animal bodies, semiconductors capable of acting as Josephson Junctions in the same way these things work in animal bodies, voids that separate different organs enabling them to perform different functions within an overarching system, as our organs do in our bodies.

You can have a hot pocket next to a cold pocket, and they will not disturb one another. Much of the cloud in space needs to contain superconductive currents, and that is easier at low temperatures, in what is called a cold plasma. But because of sheaths, you can have all that going on at cold temperatures, while at the same time having internal sheathed pockets and currents operating at extremely high temperatures.

We have also seen that the voids have regenerative capacities. We have seen that these plasmas contain seething patterns of interacting fields and currents and that these are driven to very high levels of complexity by interactions with complex dust within. There may be as yet barely understood particles involved in this drive to create complex patterns such as magnetic monopoles and tachyons.

We have looked at various theories to explain how the drive to complexity arises in the Universe as whole, and which may be pertinent to the evolution of life in plasma. We looked at Prigogine's theories of dissipative structures. There are theories of emergence and selforganization, which describe how complex things grow spontaneously and unpredictably so they become greater than the sum of their parts. And we looked at David Bohm's theory of the Implicate Order, of an ordering faculty that lies beneath the universal fields we know about.

How might complex dusty plasmas be intelligent – like plants, humans or quantum computers are intelligent?

The light that information theory throws on the nature of intelligence shows that plant life can be extremely intelligent and that plasmas may be intelligent in the same way. Plasmas compete for food, so there may also be a survival of the fittest factor driving their evolution. Like intelligent entities, plasmas may cooperate as well as compete, so that long-range-order events may involve not only communication but cooperation in the process of achieving the complexity necessary for intelligence. We have seen that ball lightning, which is made of plasma, often behaves in an intelligent manner.

We have seen that the role plasma plays in helping our own intelligence to evolve and function at high levels may also play out in plasmas in space, and that conditions may have been right for this billions of years before conditions became right for the evolution of life on Earth.

I am also suggesting that the predominant forms of life in the Universe are inorganic. The organic life forms of our planet are a footnote, not the main text, of the message of the Universe.

Just as information theory and the invention of digital computers caused us to reassess the nature and potential of intelligence, so too the development of quantum computers has opened up new horizons. Quantum computers contain plasma to help harvest the weird phenomena of the quantum realm in order to generate intelligence far greater than any digital computer. Complex plasmas also have these properties. We have seen ball lightning move through solid objects, which is an example of the phenomenon of quantum tunnelling happening in the macro world.

We have seen gigantic filaments made of plasma carrying superconducting currents with energy and information. We have seen that these plasmas contain elements that work like Josephson Junctions, used to control and fine-tune the flow of energies and information in machine intelligence, so they may have intelligence we can hardly begin to imagine.

But we have also seen that our bodies have many of the plasma features and that in addition to our meat bodies, we also have plasma bodies, and these interact with universal fields. What does this say about our own potential intelligence?

More and more is being discovered about how the human brain works. We now know that individual neurons are not the elements of the brain, it is groups of neurons that are. And these in turn operate both in parallel and in a distributed sense (in other words, not solely in one area of the brain, but distributed across regions of the brain). This kind of brain processing is called parallel distributed processing. Another name for it is connectionism.

(I have written about this at very great length in another book, so cannot repeat it here.)<sup>1</sup>

What is important for our purposes here is that intelligence emerges from the human brain not by chemicals next to each other interacting by physical proximity, but by connections over a distance. Similarly it is the concept of long-range order that is crucial to the integrity of any plasma cloud in space. This is what occurs when a very large collection of disparate particles suddenly comes together and forms a coherent entity, which extends its central control over a long distance, somehow imposing long-range order. This goes against a lot of 'conventional thinking', because it suggests action at a distance.

Isaac Newton became nearly hysterical when people spoke of action at a distance. In *Principia Mathematica* (1713), he called it 'a philosophical absurdity'. Albert Einstein was puzzled by it and called it 'spooky action at a distance'. He and two colleagues formulated a famous concept in physics called the EPR Paradox (the 'E' being for Einstein and the 'P' and the 'R' being for the other guys). This was published in 1935 and dealt with particles coordinating their momenta when very far apart, so far in fact that they would have to exchange the information with each other by sending signals at greater than the speed of light. Since Einstein himself developed Special Relativity, which insists that the speed of light must be a universal constant that cannot be exceeded, he had a special interest in this unsolved paradox of physics. I myself have entered the Special Relativity debate on the side of the speed of light as co-author of a paper with my friend Otto Rössler, which was a great honour, because he is one of the world's most famous chaos theory scientists, and the discoverer of the Rössler Attractor.<sup>2</sup>

The phenomenon of non-locality, as they call it, which was raised by this paradox, has so far been proved to occur over distances of fifty kilometres, and the phenomenon is no longer denied. A special case of non-locality is the now-fashionable subject of quantum entanglement. Entanglement has become a buzzword. What it means is that at the microscopic quantum level, things far apart can still be in contact, in other words can be 'entangled' with each other and interact. And the point about a huge plasma cloud that becomes an entity through coherence achieved despite non-locality is that is elevates the quantum state from the microscopic to the

macroscopic, in other words from the tiny to the huge. The entire cloud becomes a macroscopic quantum entity.

So how is it possible for quantum phenomena to operate at these huge sizes? We were told for decades that quantum phenomena occurred only at microscopic levels. But things have now changed.

I suspect that the answer to all this is what I discussed earlier, namely active information. Information does not have any energy or any mass. It is thus immune to the speed of light restriction, which applies only to matter, waves, and so forth. In order to extend across vast distances, information can exceed the speed of light quite happily without breaking any 'laws'. A distributed information network would act as a unifying factor to enable the cloud to achieve stability as an entity. In fact, the vast amount of information in itself might knit a filamentary network of connected elements constituting a brain, in which information processing would be inevitable.

As David Bohm and his close colleague Basil Hiley stated in 1993:

We have seen that nonlocality is contained in all the interpretations of the quantum theory that we have discussed so far ... (and) our own ontological interpretation also contains nonlocality as a basic feature.<sup>3</sup>

'Long-range order' is an example of one of the outcomes that entanglement generates. This extraordinary phenomenon means that particles or things very far apart indeed can be closely coordinated and can behave as if they are all part of one centrally controlled organism. This is what is known as quantum entanglement, which we have already mentioned.

Sometimes a system can suddenly undergo a change, known in the jargon as a phase transition, and millions of apparently separate things in the system instantaneously begin to act as one. Imagine one million people sitting in bars and pubs around the world drinking casually with their friends, and suddenly at the same instant they all stand to attention and give a salute, even though they do not know one another, have never met and never will meet. This is a phase transition, and is also referred to as the sudden onset of long-range order. No one is entirely sure how these things can happen in the natural world, but they do. And we now know that this form of coherence by means of long-range order can happen within plasma

crystals. This means that both information and energy can come from far away

Because of entanglement, not only can parts of giant dusty complex plasmas communicate with each other and form coherent patterns over distances, but giant dusty complex plasmas at the opposite sides of the Universe might in principle cooperate in the evolution of their intelligence.

# Conclusion

We have seen in this book that the Universe is over 99 per cent plasma. We have seen that dusty complex plasma interacting with electromagnetic fields can evolve sufficient complexity to count as 'alive'.

We have seen too, in certain cases, that complex dusty plasmas contain such high levels of complexity, including quantum phenomena, that it may reasonably be speculated that they are also intelligent. The Kordylewski Clouds hovering over the Earth may well be vastly more intelligent than human beings, or indeed all human beings put together, including all of those who have ever lived, so vast are the potential computing powers of the huge clouds, which together are nine times the size of the Earth, so that in size they dwarf our planet and its moon.

We have seen that plasma may be a medium by which the bizarre behaviour of particles and waves in the quantum realm may erupt into the human or macro realm, for example in the manifestation of lightning balls.

We have explored the role of plasma in the human body, showing that we may have a plasma body that shapes and sustains our physical body. We ourselves are in a sense plasmoids, and our dense matters bodies made of those rare things, atoms, are like 'smart overcoats' that we discard when we die.

The quest has only just begun. This book is intended to inform you of what is possible. Once you grasp this, you can begin to realize what you really are.

#### Notes

#### **Chapter 1: The Discovery of the Clouds**

# Chapter 2: Exploring the Nature of Plasma Clouds and Their Energy

- 1. Wang Zhehui, et al., 'Physics of Dust in Magnetic Fusion Devices', in Padma Kant Shukla, Lennart Stenflo, and Bengt Eliasson (eds.), *New Aspects of Plasma Physics*, Proceedings of the 2007 ICTP Summer College on Plasma Physics, World Scientific, Singapore, 2008, pp. 395–6.
- 2. Ions were recognized soon after we learned about the existence of atoms. In 1834 the British chemist Michael Faraday identified and named this new subdivision of matter: things which were 'almost atoms but not quite'. Because these tiny particles were detected travelling from one electrode to another in aqueous solutions, and because the act of going between things seemed to be their main characteristic at that time, Faraday looked for a Greek word to do with going or travelling. He chose the Greek verb *ienai* (a form of *eimi*), which means 'to go, come to, go across, go (along a road)', the neuter present participle of which was ion. And so he called them 'ions'.
- 3. The definition of a qudit is a bit complicated. Such a unit is considered to be a 'unit of quantum information by a superposition of d states, where d is an integer greater than 2.' That explains what the 'd' in qudit stands for.
- 4. Osamu Ishihara, 'Final Report on Study of Cryogenic Complex Plasma' submitted on 27 October 2008 to the US Research Laboratory in Japan known as AOARD, declassified by the US Department of Defense and included in the publication entitled *Charged Colloidal Structures in Plasmas*, no date. In his experiment, Osamu first created the plasma in his lab and then injected the dust particles into it, hence his particular emphasis of the interaction of the two components.

# **Chapter 3: A Brief History of Plasma Research**

- 1. In 1875, Crookes invented the vacuum tube, which came to be known as 'Crookes tubes'. You might say that we owe the entire electronic age to him. The original radios and television sets were full of those odd vacuum tubes. (In Britain they were commonly called 'valves'.) When one 'blew' it had to be replaced, like a light bulb, and if it were only in the radio, you would go to a radio parts shops and there would be shelves full of little thin cardboard boxes of different sizes. The man would rummage through his shelves and find the right one, take it down and hand it to you, saying: 'Here you are, this is the one you want.' Most people simply replaced the radio ones themselves. But it was more hazardous to open a television set, thanks to the dangers of possible electrocution, so the television repair men would come to replace the tubes in those, because they knew how to open TVs and handle the tubes safely. Even well into the 1970s, it was still possible to find valves (vacuum tubes) in small shops in most towns and buy them easily. In the 1990s, my wife Olivia and I wanted to keep an old radio set from the Second World War working and we succeeded in finding the right valve.

- 6. 'Like complex fluids, complex plasmas belong to the group of so-called soft matter ... Originally the name "complex plasma" was chosen in analogy to "complex fluids"; since complex plasmas can be regarded as the fourth state of soft matter, very much like ordinary plasmas can be regarded as the fourth state of ordinary matter ... They are responsible for fundamental astrophysical processes such as the formation of the solar systems and planets ... In particular, the question about the structure of self-organized systems emerges as a key issue ...' Patrick Ludwig, Michael Bonitz, and Jürgen Meischner, 'Complex Plasmas', in Michael Bonitz, Norman Horing, and Patrick Ludwig (eds.), *Introduction to Complex Plasmas*, Springer Verlag, Heidelberg, 2010, pp. 6–8. In the quote under bullet 2010, soft matter was referred to, and that dusty complex plasmas were types of soft matter. So what is soft matter?

There is a useful book on just this subject by Masao Doi (*Soft Matter Physics*, Oxford University Press, 2013). His very first chapter is entitled 'What is soft matter?', in which he says:

Soft matter includes a large variety of materials, typically composed of polymers, colloids, liquid crystals, surfactants [such as detergents and emulsifiers], and other mesoscopic [intermediate-sized, in other words between nano scale and micrometre scale] constituents ... Condensed states of matter are usually classified into two states, the crystalline state where the molecules are ordered, and the liquid state where the molecules are disordered. For certain materials, molecules form a semi-ordered state between crystal and liquid. Such materials are called liquid crystals ... As we have seen, soft matter includes a large class of materials ... What is common in the above materials is that they all consist of structural

units that are much larger than atoms ... soft matter consists of large molecules or assemblies of molecules which move collectively ... the fundamental structural units of soft matter are very large.

- 13. The ancient Greek mystics when discussing what mystical writers such as the Theosophists call 'the subtle body', in other words the soul, called it the *lepton ochēma* in the ancient book called The Chaldaean Oracles, the word ochēma meaning not 'body' but 'vehicle'. This use of the word lepton gives it an extended meaning, which one could call 'lighter than light', since lightness has here been stretched to mean so light that it is barely material at all. (Or one might say it was their way of trying to give a name to what we call plasma, the existence of which they intuited but did not yet understand.) The name *baryon* was thus invented to describe the particles that were very different from electrons, such as protons and neutrons, and which are so much heavier than electrons, having so much more weight, or as one might more correctly say, rest mass. The proton, for instance, has 1836 times more rest mass than an electron, is thus heavy, or as the Greeks would have said, barys, 'weighty'. In 2016, I published a lengthy paper explaining why protons are exactly 1836 times heavier than electrons, which people interested in more detail on this subject can download from my www.researchgate.net entry, as my explanation was entirely new and had never been suggested before. There are very many types of baryons known now, but we cannot go into such a complicated discussion or give the lengthy lists of them here. The name baryon comes from the ancient Greek word baros, which means 'weight'. Electrons are small, fast, and light, and they are in a different class of particles known as leptons, from the ancient Greek word *leptos*, which means 'small' and also 'light, as in faint breezes and light wine'. Coincidentally, the Greeks also used lepton to describe the size of dust particles

- 2. C. [Cecil] Maxwell Cade and Delphine Davis, *The Taming of the Thunderbolts: The Science and Superstition of Ball Lightning*, Abelard-Schuman, London, 1969.
- 3. And because ball lightning has often been associated with poltergeist phenomena, and poltergeists have so often been associated with the strange emotional energies of teenage girls, it seems to me that it is not impossible that poltergeist-related ball lightning might be created by intensely neurotic teenage girls' own abnormal energy fields.
- 4. I have no view on the matter. Robots can certainly be organic. Clunky metallic robots are a childhood fantasy. It is possible that the proponents of 'transhumanism' know all of this very well. After all, I suspect that DARPA is well aware of what I am suggesting. And they probably assume that the clouds are hostile, if only because DARPA assumes everyone and everything is hostile. It is, after all, the job of the security agencies to be paranoid. And they certainly do not let us down in that. Plus, there's a lot of psychosis thrown in. When you get a paranoid psychopath, then you have the real thing, the perfect security agent.

- 9. Abrahamson, John (ed. and contrib.), *Ball Lightning Theme Issue, Philosophical Transactions A of the Royal Society*, London, 2002. (Contains contributions by John Abrahamson, Alexander Vladimirovich Bychkov, Vladimir L. Bychkov, Celia I. Merzbacher, Stanley Singer, and D.J. Turner.

10. Some of their interesting scientific ideas about ball lightning will come into our discussion later in connection with the nature of complex plasmas. I shall not even attempt to summarize the contents of this fascinating book, as it would take too long, except to point out that it consists of contributions by six separate scientists of high repute, and should be studied carefully by anyone intending to study ball lightning.

The other source I should mention appeared piecemeal during 2015, and consists of a series of booklets in English translation by two Russian scientists of the Institute of Informatics Problems of the Russian Academy of Sciences in Moscow, named Vladimir Pavlovich Torchigin and Alexander Vladimirovich Torchigin. Vladimir Torchigin is the head of the Department of the Problems of Design of Information Computing Systems of High Parallelism at his Institute. Alexander Torchigin is the son of Vladimir Torchigin, as is a third Torchigin at the Academy, who has not written about ball lightning, Sergey Vladimirovich Torchigin. The English translations are grammatically imperfect in many places, and one must make allowance for that fact in reading the booklets.

In one of their booklets, the two Torchigins point out that there have been more than 2000 papers and reports about ball lightning published, containing more than 200 theories of what ball lightning is, and then they say: 'But none of these theories seems to have gained general acceptance because they fail to explain all observed characteristics of the phenomenon.' They also mention that as little as 20 years ago some scientists still doubted the existence of ball lightning. However, they point out that as there are now more than 10,000 recorded accounts of ball lightning, there can be no doubt that it exists! (Vladimir Pavlovich Torchigin and Alexander Vladimirovich Torchigin, *Clue of Ball Lightning Puzzles: Ball Lightning Is the Light Rather than Matter*, no publisher named so privately published, 2015, pp. 5–6.)

The word 'the' in the title is an example of the imperfect grammar of the text. Errors with the use of definite articles are perhaps the single most common error made by non-native translators into English. The theories of Vladimir Torchigin are very interesting and novel. He believes that ball lightning is made out of trapped light rather than plasma. However, he says (and I have slightly improved his grammar): '... there is usually no plasma within Ball Light after its generation. There is certainly no plasma after Ball Light penetrates through windowpanes because plasma cannot penetrate through glass.' (Vladimir Pavlovich Torchigin, *Ball Lightning Physics: No Plasma and Electricity Are Required*, no publisher so privately published, 2015, p. 198.)

Torchigin is erroneous here, but may be forgiven for not knowing about the most recent findings, which are known only to a small number of scientists at the moment. The latest discoveries about complex plasmas are so astounding that we now know that they can indeed penetrate not only glass but any form of solid dense matter. I wish to make the point that the Torchigins have done a good service by discussing confined and trapped light within the context of ball lightning. As we will see later, the creation of 'a new kind of light' and the 'confinement of light' have now both been accomplished in the laboratory, and ironically, the most exciting part of this work has taken place recently in Russia, though because it is known to such a small number of specialists, it is not yet known to the Torchigins.

We will see later when we come to the full explanation of complex plasmas, which is what I believe that we all are as living entities, that the instinct followed by the Torchigins in attempting to explain ball lightning as confined light without the presence of any plasma is useful and has important and indeed essential insights to offer, because 'confined light' is indeed part of the answers we are seeking, but within the contexts of highly complex plasmoids.

- [Proceedings of the USSR Academy of Science], Vol. 101, No. 2, 1955, pp. 245–8. An English translation of this article was published in 1961, in: Donald J. Ritchie (ed.), Ball Lightning: A Collection of Soviet Research in English Translation, Consultants Bureau, New York, 1961, pp. 11–15.
- 12. He believes radiation that is reflected off the surface of the Earth causes interference patterns as a result of which 'standing waves are set up, and at a distance equal to  $\lambda$ , the wavelength, multiplied by 0.25, 0.75, 1.25, 1.75, etc., there will be antinodes fixed in space at which the intensity of the electric field is doubled as compared with that of the incident wave. Because of the increased intensity in the neighbourhood of these surfaces, conditions will be suitable both for the formation of an initial [electric] discharge as well as for the further development and maintenance of the ionization in the cloud in which the ball lightning is formed.' (I should explain that the Greek letter *lambda* above is the standard symbol used in physics for 'wavelength'.)

#### **Chapter 6: When Heaven Was Young**

- 1. *Pistis Sophia*, edited by Carl Schmidt, translation and notes by Violet Macdermot, The Coptic Gnostic Library, Vol. IX, Brill, Leiden, 1978, pp. 184–7. (The textual reference is Book Two, Chapters 83 and 84.) There is an earlier translation of this work by G.R.S. Mead, which is also very good. The Brill volume is 806 pages, because the *Pistis Sophia* is immensely long.
- 2. This is related in *The Apocryphon of John*, for which see below, footnote 11.
- 3. In one translation known as the Darby Bible Translation, the bush is described as a thorn-bush. Commentators point out that the Hebrew word for the bush is *seneh*, which is the name of a thorny bush, a species of acacia, common in Sinai. But the original Hebrew language version is lost, and *seneh* is a translation into Hebrew from the Greek Septuagint where the Hebrew translator has used creative licence. (*Seneh* is thus a product of reverse-engineering by a Hebrew translator who has added it, thinking that he was thus being helpful to readers.) In the Septuagint, which is the oldest text of Exodus in existence, the Greek word for the bush is *batos*. That means a bramble, in other words a wild raspberry or blackberry bush, not any other bush or plant such as buckthorn or acacia.

Theophrastus, the colleague and successor of Aristotle, was the founder of scientific botany, and the authoritative expert on Greek botanical terminology of the fourth century BC, taking precedence even over the herbalist Dioscorides, who lived AD 40–90 and was three centuries later. In his *Peri Phytōn Historias*, III, xviii, 4, Theophrastus explains that *batos* is a broad term for bramble-like plants.

He says: 'Of the bramble (*batos*) again there are several kinds, showing very great variation; one is erect and tall, another runs along the ground and from the first bends downwards, and when it touches the earth, it roots again; this some call "the ground bramble". The "dog's bramble" (the wild rose that we today call the dog rose, thus continuing the ancient Greek name associated for unknown reasons with dogs) has a reddish fruit like that of the pomegranate, it is intermediate between a shrub and a tree; but the leaf is spinous.' (Theophrastus, *Enquiry into* 

*Plants*, translated by Arthur F. Hort, Loeb Classical Library, Harvard University Press, Vol. I, 1916, pp. 270–1.)

Obviously the Burning Bush could not have been either the creeping bramble or the dog rose, and can only be the one that is 'erect and tall'. As for the masculine noun *batos* meaning a blackberry bush, it is worth noting that the neuter noun *baton* specifically means 'a blackberry'. The other word for a prickly shrub, often applied to buckthorn for instance, was *rhamnos*, and there was also the word *philukē*, which referred to an evergreen prickly shrub. It seems therefore that if the Septuagint had intended a prickly shrub other than the bramble, such as buckthorn, the word *rhamnos* would have been used instead of *batos*. And if acacia had been meant, its Greek name *akantha* would have been used. Hence the translation of *batos* as *seneh* was evidently incorrect.

It seems that in the earliest surviving text we are stuck with the unlikely and somewhat inglorious bramble, which sprawls at the sides of most English roads and hedges and from which country children pick berries to make jam in the autumn. Somehow, that is extraordinarily mundane for a divine epiphany. It is hardly surprising, therefore, that we are never told this by theologians, as the idea that Moses went up onto a mountain in order to converse with a burning blackberry bush is unimpressive.

4. It is necessary to say more about the mysterious 'Angel of the Lord', since this anomaly in both the Jewish and Christian religious traditions is usually ignored. Who and what was the 'Angel of the Lord'? This divine entity of the burning bush, who was not 'the Lord' but was someone or something else closely associated with 'the Lord', was known in very ancient Judaism (which testifies to the antiquity of the Moses account, I might add), but had been either forgotten or banished as heretical by the time of the sect of Judaism known as the Sadducees, who were the 'Temple Jews' of the Jerusalem Temple against whom Jesus struggled so energetically.

The Sadducees were a very vicious and murderous ruling theocratic sect. Biblical scholars have discovered that during the lifetime of Jesus, the Sadducees arrested and executed more than 6000 Jewish rabbis of the Pharisee sect, solely because they were rivals for control. The Sadducees were therefore a violent, bloodthirsty mafia using religion as their pretext for control over society. What the Sadducees did to the more mystical Jews such as the Gnostics was probably even worse than the massacres of the Pharisee rabbis, though the numbers of Gnostics within reach of Jerusalem was much smaller. Some of them, the Essenes, had fled to live in caves beside the Dead Sea, in order to avoid being murdered by the Sadducees.

The seizure and execution of Jesus was part of a wider and uniform purge by the Sadducees of all the Jewish rabbis or religious leaders who in any way challenged the Sadducees' monopoly of power. I could elaborate on this subject and explain the real significance of the 'overturning of the tables of the moneychangers in the Temple' by Jesus, but this is not the place to do so, interesting as the subject is. North of Jerusalem lay the region of the Samaritans, who were a branch of the Jewish people who had escaped the control of the Jerusalem Temple mafia. They preserved some of the more ancient Jewish knowledge and traditions that the Sadducees had thrown overboard. Among these was the tradition and explanation of 'the Angel of the Lord'.

The Dutch Biblical scholar Jarl Fossum was the first academic who explored in depth this fascinating information, which he articulated in his PhD thesis of 1981 (supervised by the famous Professor Gilles Quispel, one of the world's leading Biblical scholars) and in the same year in an article in a scholarly anthology, Fossum, Jarl, 'Samaritan Demiurgical Traditions and the Alleged Dove Cult of the Samaritans', in Roelof van den Broek and Maarten Jozef Vermaseren (eds.), *Studies in Gnosticism and Hellenistic Religions Presented to Gilles Quispel on the Occasion of His 65th Birthday*, Brill, Leiden, 1981, pp. 143–60.

This was later followed by his book, *The Name of God and the Angel of the Lord: Samaritan and Jewish Concepts of Intermediation and the Origin of Gnosticism*, J.C.B. Mohr, Tübingen, 1985, which was based on his thesis. The ancient Jewish conception preserved by the Samaritans was that 'the Angel of the Lord' was the divine entity who actually created the bodies of men, while 'the Lord' infused spirits into those bodies. As Fossum puts it: '... the creation of the body of Adam from the earth is ascribed to the Angel of the Lord, while the infusion of the spirit into this corpus is a work assigned to God ...'

The Samaritans claimed to know the actual name of the Angel of the Lord, which was Kebala, which means 'the Secret'. They maintained that it was the Angel Kebala who really resided in the sanctuary of the Temple, not God himself (who remained in Heaven), and that Kebala was the mediator between God and humankind. Moreover, his glowing or burning nature is suggested by the Samaritans calling Kebala 'the Glory who fills the Tabernacle', and they say that he also manifested himself as Glory at the door of the Tent of Meeting in the passage of Exodus that commences at 21, 42 (ibid., pp. 143, 157–9). The Samaritans claimed that Kebala abided at Bethel, which means 'House of God', on top of Mount Gerizim.

I cannot go further into this interesting ancient variation of Judaism, which has been lost now for nearly 2000 years, but I wanted to offer this information to help explain the identity of 'the Angel of the Lord' for justly puzzled readers. A few years before Fossum's important researches into the Samaritans, Alan F. Segal had partially addressed the problem in his fascinating book *Two Powers in Heaven*, in which he speaks of numerous early Jewish sects (when Judaism was not yet forcibly unified by a central theological authority at the central Jerusalem temple), who insisted that God had a divine deputy (a lesser god) who did all his work for him regarding the Earth and humans.

Probably the most frequently occurring name for this entity is Metatron. Segal also quotes numerous rabbinical sources regarding further details of the myth or legend of the ascent of Moses up the mountain. Some of these contain further plasmic details. For instance, there is a strong Jewish tradition that Moses was taken up from the mountain to heaven in a 'cloud', and a text known as the Pesikta Rabbati (20, 4), says:

'Then a troop of angels of destruction, strong and mighty, who are set round about the throne of glory, met him. When Moses reached them, they sought to burn him with the breath of their mouths. What did the Holy One, blessed be He, do? He spread something of his own splendour about Moses ... (this) prove(s), according to Rabbi Nahum, that the Almighty spread about Moses something of the splendour of the presence of God, which is His cloud.'

Alan F. Segal, Two Powers in Heaven: Early Rabbinic Reports about Christianity and Gnosticism, Brill, Leiden, 1977, p. 145.

One is tempted to wonder if the ancient Jews somehow realized that the Kordylewski Clouds existed, perhaps as a result of telepathic shamanic journeys. One could even construe these ancient Jewish ideas as suggesting that the Kordylewski Clouds are indeed Metatron. The subject of Metatron, who was traditionally the highest of the angels in both mystical Judaism and Islam, is especially intriguing considering that there was an ancient Jewish tradition that there were two Metatrons. One was called Prince of the Countenance and the other was called Yahoel. And one ancient text says that 'the Ancient of Days' mentioned in the Biblical Book of Daniel is really Metatron.

Metatron is also mentioned in the book 3 Enoch, and Enoch was said to be transformed into (or absorbed into) Metatron when he was raised in his ball of fire to the heavens. In that book, Metatron is also said to have seventy names, of which the first and chief was Yahoel (sometimes

abbreviated as Yol). The Muslim name of Metatron is Mitatrush, which means 'the angel of the veil'. In the mystical Jewish book *The Apocalypse of Abraham*, Yahoel is described as 'the spiritual teacher of the Patriarch' (Abraham), who taught Abraham the whole of the Torah.

The great scholar Gerschom Scholem concludes that Metatron, whose original name was Yahoel, was 'the highest of all created beings'. The name Yahoel was a 'mystic name' according to Scholem and thus had no etymological meaning. The suffix el is, I am told, an honorary termination for the name of any angel, and means 'lord', used in the polite sense only, not in the literal sense of 'the Lord'. As for Yaho (the part of the name that precedes the honorific el), Scholem points out that it is an abbreviation of the name YHWH, i.e., Yahweh, whom we call in English Jehovah. But he stresses that the intention was not that Yahoel was meant to be Jehovah, but that his high status was meant to be signalled by the fact that his mystic name contained the name of the supreme God.

Scholem says that this explains the puzzling passage in the Book of Exodus (XXIII, 20 ff.): 'Beware of him for my name is in him.' And in The Apocalypse of Abraham, Yahoel is quoted as saying to Abraham: 'I am called Yahoel ... a power in virtue of the ineffable name that is dwelling in me.' And Jewish Gnostic literature makes explicit that Yahoel was not Yahweh, but was 'the lesser Yaho', (Gerschom Scholem, *Major Trends in Jewish Mysticism*, Schocken Publishing House, Jerusalem, 1941, pp. 66–9). That is essentially the same as saying that he was the Angel of the Lord, who as we know appeared as a glowing ball, so that we may assume that Yahoel was one, too.

This subject could be discussed at very great length indeed, to the great discomfort of 'normative rabbinical Judaism', as Gerschom Scholem (whom I was fortunate enough to know) called the dominant Judaism that exists in our contemporary world. The earliest name for God in Judaism appears to have been Elohim, and there is no escaping the embarrassing fact that that name is plural. In other words, there is little indication that the earliest Judaism was monotheistic, and 'the Angel of the Lord' was apparently left over from the earliest Judaism and only awkwardly accommodated in orthodoxy.

- 5. Another translation of these passages may be found in the book *1 Enoch: A New Translation*, by George W.E. Nickelsburg and James C. VanderKam, Fortress Press, Minneapolis, Minnesota, USA, 2004, pp. 34–6.
- 6. It was G.R.S. Mead who spotted and translated this fragment of a lost work by Damascius, which he found in the tenth-century Byzantine encyclopaedic lexicon named the *Suda*, which until contemporary times was mistakenly called 'Suidas'. (Refs: p. 194 of Bekker's edition of 1854, or I. 850 f. of Bernhardy's edition of 1853.) See G.R.S. Mead, *The Subtle Body*, J.M. Watkins, London, 1919, p. 80 and note. The fragment comes from a lost work entitled *Life of Isidorus*. Isidorus was the husband of Hypatia and friend of Proclus and Marinus. What a pity that work is lost!

Mead's translation of this passage by Damascius first appeared in the quarterly journal he edited named *The Quest*, Vol. I, No. 4, July 1910, pp. 708–9, where he inserted some of the Greek words of the text as part of an extended discussion of the terminology used. To discuss the many points arising from all of this would unfortunately be out of place here.

7. Translation by G.R.S. Mead; see Mead, op. cit., p. 88 and note. A more recent translation has also been published since Mead's time; see Philoponus, *On Aristotle's 'On the Soul'*, I, 1, 18. 27–33, translated by Philip J. van der Eijk, *Philoponus on Aristotle's 'On the Soul I.1–2'*, Cornell University Press, Ithaca, New York, USA, 2005, p. 34.

His translation reads: '... there is yet another body eternally attached to it [the pneumatic body], which is celestial and therefore eternal, which is called luminous or astral. For as the soul belongs to the cosmic entities, it must have a share assigned to it which it manages, being part of

the cosmos; and if it is always in motion and always has to be active, it must have a body eternally attached to it which it will keep alive always; this is why they say the soul always has the luminous body, since this is eternal.' On pp. 123–4, van der Eijk's footnote 183 gives a lengthy historical survey of this concept of a 'radiant' or 'luminous' body, citing Plotinus, Porphyry, Iamblichus, Synesius, Hierocles, Proclus, and numerous modern scholars who have discussed the subject. We do not have space to survey this fascinating subject here.

- 8. The Apocalypse of Adam (the fifth and final tractate from Nag Hammadi Codex Five), edited and translated by George W. MacRae, in *The Coptic Gnostic Library: Nag Hammadi Codices V, 2–5 and V with Papyrus Berolinensis 8502, 1 and 4*, ed. by Douglas M. Parrott, Brill, Leiden, 1979, pp. 151–95. See also Charles W. Hedrick, *The Apocalypse of Adam: A Literary and Source Analysis*, Wipf & Stock Publishers, Eugene, Oregon, USA, 2005, for further background and analysis of this tractate.
- 9. *Marsanes* (from Nag Hammadi Codex 10), introduced, edited and translated by Birger A. Pearson, in *The Coptic Gnostic Library: Nag Hammadi Codices IX and X*, ed. by Birger A. Pearson, Brill, Leiden, 1981, pp. 229–347.
- 10. *The Paraphrase of Shem* (Tractate One of Nag Hammadi Codex Seven), introduced and translated with commentary by Michel Roberge, Brill, Leiden, 2010.
- 11. *The Apocryphon of John* (from four sources: Nag Hammadi Codices II, 1; III, 1; and IV, 1, as well as Papyrus Berolinensis 8502, 2), edited and translated by Michael Waldstein and Frederik Wisse, Brill, Leiden, 1995. The Noah passage may be found preserved in three slightly varying versions on pp. 162–5, all three of which specifically mention the 'luminous cloud'.
- 12. He also postulated the existence of something he called pneuma, which existed and intermingled with things here on earth and was, for instance, present in animal and human sperm. These ideas are expressed in Aristotle's lengthy zoological works, which few people today ever read. I had to read them all thoroughly because I was asked to do a general review of them for *Nature* some years ago. (Robert Temple, 'The Roots of Nature', in *Nature*, Vol. 359, No. 6395, 8 October 1992, pp. 489–90.) This article may be downloaded from my researchgate.net entry. In it, I reconstructed the outline of his 'lost' zoological work, *Close Investigations of Things According to Kind and I also surveyed all of the botanical works of Aristotle's successor and friend, Theophrastus.*

Before writing that article, I read closely every word in translation of Aristotle's surviving zoological writings and Theophrastus's botanical writings, all the footnotes, and checked lots of the original text with particular attention to the vocabulary, as I went along, which was an immense task, frankly, but well worth it. I do not believe that many classical scholars have ever done that. As for reading them all the way through in Greek, I have known a few scholars (such as Alan Gotthelf) who did that for the zoological works, but they did not extend their efforts to the botanical works as well.

Pneuma and aither were related, but aither was the pure form, which was restricted to the higher levels of reality, and pneuma was that lower and distinctly impure form that intermingled with and helped to animate ordinary matter. Aristotle's concept of pneuma had a big influence on early Church Fathers and Christian theology, helping to inspire the Christian concept of the logos as the 'word of God' and Jesus as the aetheric being who became pneumatic to save us by bringing some of the aither down into corrupt matter to infuse it with light. These concepts inspired the Gospel of John in the Bible, and permeated even more thoroughly the ancient Gnostic texts. But these subjects are all another story that we cannot discuss further here.

13. Aristotle also stated that he believed there were exceptions to the parallel postulate in geometry, thus anticipating modern relativity theory. And he discovered the Eustachian tubes in the human ear approximately 1900 years before Bartolomeo Eustachi (1500–1574), to whom the discovery is normally attributed, and after whom they are named. For an account of this, see Robert Temple,

- 'Aristotle as Anatomist and Dissector: The Marvels of Nature', in *Helix: Amigen's Magazine of Biotechnology*, Vol. II, Issue 2, Bugamor International BV, Almere, Netherlands, 1993, pp. 49–55. The text is Aristotle, *Historia Animalium*, Book One, 502a17-502b27. This article may be downloaded from my Researchgate entry or from my personal website. But enough of Aristotle, that is, if one can have enough of Aristotle.
- 14. The Chinese texts for these passages, with translations and comments, may be found in Herbert A. Giles, 'The Remains of Lao Tzu', in *The China Review: or, Notes and Queries of the Far East*, China Mail, Hong Kong, Vol. XIV, issue for March and April, 1886, p. 244.
- 15. Olivia Temple and Robert Temple, *The Sphinx Mystery*, Inner Traditions, Rochester, Vermont, USA, 2009, p. 393.

#### Chapter 7: Kristian Birkeland's Miraculous Discovery

- 1. Harald Falck-Ytter, *Aurora: The Northern Lights in Mythology, History and Science*, Bell Pond Books, Hudson, New York, USA, 1999, p. 49. This is the English translation of *Das Polarlicht*, Stuttgart, 1983.
- 2. Aristotle, *Meteorologikōn* (*Meteorology*, but often referred to in Latin as the *Meteorologica*), Book One, Chapters 4 and 5, 341b1-342b24. See Aristotle, *Meteorologica*, trans. by H.D.P. Lee, Loeb Classical Library, Harvard University Press, 1952, pp. 28–39.
- 3. Falck-Ytter, op. cit., p. 45.
- 4. Aristotle, op. cit., Chapters 3 and 4, 340b25-7 and 341b1-24, pp. 19–23, 29–31 ('We maintain that the celestial region as far down as the moon is occupied by a body which is different from air and from fire ... what we are accustomed to call fire, though it is not really fire ... We must suppose therefore that the reason why clouds do not form in the upper region is that it contains not air only but rather a sort of fire ... immediately beneath the circular celestial motion comes a warm and dry substance which we call fire. We must think of the substance we have just called fire as extending round the outside of the terrestrial sphere like a kind of inflammable material ...')
- 5. Heraclitus, *Homeric Problems*, ed. and translated by Donald A. Russell and David Konstan, Brill, Leiden, 2005, Book 23, p. 45.
- 6. Plutarch, 'Life of Lysander', Chapter 12, in *Plutarch's Lives* (in four vols.), trans. by Aubrey Stewart and George Long, Bohn's Classical Library, George Bell & Sons, London, 1895, Vol. 2, pp. 294–5.
- 7. Lucius Annaeus Seneca, *Questiones Naturales (Natural Questions)*, trans. as *Physical Science in the Time of Nero: Being a Translation of the* Questiones Naturales *of Seneca*, by John Clarke, with Notes by Sir Archibald Geikie, Macmillan and Co., London 1910, pp. 37–41; more recently, Seneca, *Naturales Questiones*, 2 vols., trans. by Thomas H. Corcoran, Loeb Classical Library, Harvard University Press, 1971–2, Vol. I, pp. 73–83.
- 8. Pliny, *Natural History*, Book Two, Chapter 26 or 27 depending on the edition. In Bohn's Classical Library, trans. by John Bostock and H.T. Riley, Henry G. Bohn, London, 1855, Vol. 1, pp. 60–1, it is Chapter 27. In the Loeb Classical Library, trans. by H. Rackham, Harvard University Press, Vol. 1, p. 241, it is Chapter 26, which becomes 27 in the middle of a sentence. Puzzled by this, I checked the earliest translation done in Elizabethan times by Philemon Holland, of which I am fortunate to own copies of both the first edition of 1601 and the second edition, which appeared in 1635, and there it is Chapter 27, and the passage is found on p. 17.

Holland's translation reads: 'There appeareth in the Sky also a resemblance of bloud, and (than which nothing is more dread and feared of men) a fiery impression, falling from out of heaven to

earth, like as it hapned in the 3 yeare of the 107 Olympiad, at what time King Philip made all Greece to shake with fire and sword.' The Bohn's translation reads: 'There is a flame of a bloody appearance (and nothing is more dreaded by mortals) which falls down upon the earth, such as was seen in the third year of the 103rd Olympiad, when King Philip was disturbing Greece.' The Loeb translation says: 'There also occurs a yawning of the actual sky, called *chasma*, and also something that looks like blood, and a fire that falls from it to the earth – the most alarming possible cause of terror to mankind; as happened in the third year of the 107th Olympiad, when King Philip was throwing Greece into disturbance.'

- 9. Falck-Ytter, op. cit., pp. 54–5.
- 10. Jean-Jacques d'Ortous de Mairan, *Traité Physique et Historique de l'Aurore Boreale (Physical and Historical Treatise concerning the Aurora Borealis*), Pierre Mortier, Amsterdam, 1735, 393 pp., with 17 folding plates. On the title page it is stated that the book is composed of a 'suite' of papers delivered to the Académie Royale des Sciences (in Paris) in 1731. I have an original copy of this book.
- 11. I have a copy also of this German edition, which appears in Wolf Balthazar Adolph von Steinwehr (1704–1771), translator and editor (with some commentary), Vol. 9 of *Der Königliche Academie der Wissenschaften in Paris Physiche Abhandlungen ... welcher die Jahre 1731, 1732, in sich hält*, Breslau, 1753. (Please note that Wikipedia is incorrect in listing the year 1760 as publication date for this volume, though it may have been reprinted then perhaps.) The de Mairan material extends from p. 248 to p. 564. De Mairan is called von Mairan in this volume.

The Aurora Borealis in German is called *die Nordlichtern* (the Northern Lights). Only 9 of the 17 plates that appear in the 1735 French volume are found in this German edition. This series of volumes in German is essentially a translation of the Proceedings of the Royal Academy of Sciences in Paris. It should be noted that the 1731 publication by the Academy in Paris was used for the translation, and not the 1735 book, which may have been expanded and provided with additional illustrations. I have not compared the 1731 publications with the 1735 volume, so cannot state anything authoritatively about variations in the texts.

- 12. Knud Leem, *Beskrivelse over Finmarkens Lapper* (*An Account of the Lapps of Finmarken*), Copenhagen, 1767. A reproduction of Leem's engraving was published by Lemström, Vol. 1, p. 238, and is reproduced from that on this book's website. For Lemström, see footnote 17 below.
- 13. Sir Humphry Davy, 'Of Electrical Attraction and Repulsion, and Their Relations to Chemical Changes', in *Elements of Chemical Philosophy*, London, 1812.
- 14. Baron Karl von Reichenbach, *Researches on Magnetism, Electricity, Heat, Light, Crystallization, and Chemical Attraction in Their Relation to the Vital Force*, translated and edited by William Gregory, Parts I and II, London, 1850, p. 5.
- 15. Ibid., pp. 445–51.
- 16. Arthur-August De La Rive, 'Nouvelles Recherches sur les Aurores Boréales et Australes et Description d'un Appareil', Extrait des *Mémoires de la Societé de Physique et d'Histoire Naturelle de Genève*, Vol. 16, 2nd Part, Geneva, 1862.
- 17. Karl Selim Lemström, 'On the Periodic Variations in Some Meteorological Phenomena, Their Connection with the Changes of the Solar Surface and Their Probable Influence on the Vegetation', in *Finsk Tidfkrift*, 1878. This article is in Swedish.
- 18. Sophus Tromholt, *Under the Rays of the Aurora Borealis in the Land of the Lapps and Kvaens*, edited by Carl Siewers, 2 vols., Houghton Mifflin, Cambridge, Massachusetts, USA, 1885. The section entitled 'On the Aurora Borealis' is found in Vol. 1, pp. 192–288, with numerous illustrations.
- 19. Adam F.W. Paulsen, *Résumé des Travaux de l'Expédition Internationale Danoise Faits a Godthaab (Groënland Occidental) 1er Aout 1882–31 Aout 1883* [1 August 1882–31 August 1883], Danish Meteorological Institute, Copenhagen, 1884.

- 20. Nils Adolf-Erik Nordenskiöld, 'Sur les Aurores Boréales Observées Pendant l'Hivernage de la Véga au Détroit de Behring (1878–9)', in *Annales de Chimie et de Physique (Annals of Chemistry and Physics*), Sixth Series, Vol. 1, Paris, January 1884, pp. 5–72. His earlier publication in Swedish was 'Om Norrskeneen under Vegas Öfvervintring vid Berings Sund (1878–9) af A.-E. Nordenskiöld': extracted from *Vega-expeditionens Vetenskapliga Iaktagelser*, pp. 403–53 of Vol. 1, Stockholm, 1882. Nordenskiöld published a mammoth account of the Vega Expedition in 5 volumes, as well as a popular summary in 2 volumes, but these extracts related to the Aurora Borealis, as they appeared first in the original Swedish and then in the French translation.
- 21. Kristian Birkeland, in *Archives des Sciences Physiques et Naturelles (Archives of the Physical and Natural Sciences*), Geneva, June 1896 (in French). Perhaps Birkeland chose this journal because in its earlier incarnation it had published de la Rive's account of the aurorae in 1862, thirty-four years before; see footnote 16 above.
- 22. Kristian Birkeland, Expedition Norvegienne 1899–1900 pour l'Étude des Aurores Boreales Resultats des Recherches Magnetiques [sic. some acute accents omitted from title as printed], Jacob Dybwad, Christiania [now called Oslo], Norway, 1901. See p. 39, where in a footnote Birkeland refers to the article published by himself in the Archives des Sciences Physiques et Naturelles (see footnote 16 above). I have not found or consulted the original article and do not have its title and pagination.

# **Chapter 8: The Cosmic Web**

- 1. I should point out that all power transmission lines on Earth are double, either in the form of a 'two-wire line' or a single wire inside a tube, which is known as a coaxial cable. (Transmission lines can of course be multiple, but they must at the very least be double.)
- 2. John P. Cullerne and Anton Machacek, *The Language of Physics: A Foundation for University Study*, Oxford University Press, 2008, p. 51.
- 3. This reminds me of the Berry Phase in physics, named after Michael Berry, a professor at Bristol University. He showed that if you mathematically transport a vector (the technical name for a line in a diagram showing the direction of a certain force, and which can actually be drawn with an arrow showing that direction) along the surface of a sphere from point A to point B, by the time it gets there it is not straight any more but is at a slight angle, because its path has curved due to moving along the spherical surface. (Berry's student John Hannay demonstrated that this is true in classical physics as well as in quantum physics, and the angle is named after him as the Hannay Angle.) I mention this because if we consider the spiralling aspect of the electric field, introducing as it does a curved path rather than a straight one, perhaps the introduction of that curvature causes the small deflected angle of the Hall Effect to appear, and the angle of the Hall Effect is therefore related to the Hannay Angle because of the curvature.

# **Chapter 10: Invisible Earth**

1. Thomas Gold, *The Deep Hot Biosphere*, Copernicus, Springer Verlag, New York, 1999. He did not remain connected with plasma research, however, as he had other interests such as cosmology and, towards the end of his life, deep carbon stores beneath the surface of the Earth. Tommy was also a founder, with Fred Hoyle and Hermann Bondi, of the steady state theory of the Universe, which neither he nor Fred (whom I also knew well) ever abandoned, though of course they held to it in a modified form to take account of the many objections made against it by cosmologists determined to believe in what Fred had derisively named 'the Big Bang', a name that has stuck and unfortunately is still taken seriously, along with the ridiculous theory to which it is attached.

In 2017, I published a paper proposing an alternative explanation of what is known as 'the cosmic microwave background radiation temperature', the primary basis for the Big Bang Theory. Robert Temple, 'A New Explanation for the Cosmic Microwave Background Radiation Temperature', in *Journal of Cosmology*, Vol. 26, No. 11, 2017, pp. 14790–803.

# **Chapter 11: Radiant Matter, Plasma and Plasmoids**

- 1. Winston Harper Bostick, 'Experimental Study of Ionized Matter Projected across a Magnetic Field', *Physical Review*, Vol. 104, No. 2, 15 October 1956, pp. 292–9, plus seven pages of captioned plates.
- 2. Robert Temple, 'Is Particle Mass a Function of Degrees of Freedom?', in *Journal of Cosmology*, Vol. 26, No. 3, January 2016, pp. 13995–14090; see p. 66 of the paper.
- 3. E.G. Harris, R.B. Theus, and Winston Harper Bostick, 'Experimental Investigations of the Motion of Plasma Projected from a Button Source across Magnetic Field', *Physical Review*, Vol. 105, No. 1, 1 January 1957, pp. 46–50.
- 4. Winston Harper Bostick and Lyman Spitzer, *Plasma Physics: Selected Reprints*, American Association of Physics Teachers, 1963.

- 6. Winston Harper Bostick, 'Experimental Study of Plasmoids', in Bo Lehnert (ed.), *Electromagnetic Phenomena in Cosmical Physics*, Proceedings of the International Astronomical Union Symposium No. 6, held in Stockholm, August 1956, Cambridge University Press, 1958, pp. 86–98 (includes one and a half pages of discussion at the end, including further elucidations by Bostick).

# **Chapter 12: Plasma Comes Alive**

1. Kaushik Roy and Prasanta Chatterjee, *Nonlinear Structures in Dusty Plasma*, Lambert Academic Publishing, Saarbrücken, Germany, 2012, p. 2.

- 2. I have discussed the Kelvin Scale at some length in my scientific paper of 2017 about the cosmic background radiation: Robert Temple, 'A New Explanation for the Cosmic Microwave Background Radiation Temperature', in *Journal of Cosmology*, Vol. 26, No. 11, 2017, pp. 14790–803.
- 3. Mazuo Minami, Chikara Kojima, Takeo Ohira, and Osamu Ishihara, 'Microwave Measurement of Decaying Plasma in Liquid Helium', Appendix One to Osamu Ishihara, 'Final Report on Study of Cryogenic Plasma in Superfluid Liquid Helium', submitted to AOARD 23 August 2005, declassified by the US Department of Defense. The Appendix was released for publication in *Transactions on Plasma Science of the IEEE*, August 2005 (8 pp.)
- 4. Ibid., p. 4.
- 5. Norman R. Bergrun, *Ringmakers of Saturn*, Pentland Press, Edinburgh, 1986. The late Norman Bergrun was a scientist who had an entirely different explanation for the 'spokes'. In 1986, he published his book *Ringmakers of Saturn*, which suggested that not only the spokes of Ring B but the whole of Ring A of Saturn were being artificially created by mysterious cylindrical craft of extraterrestrial origin, possibly manned by intelligent robots. Both in his book and in many later talks, some of which can readily be found on the internet, Bergrun has shown photographs of strange cylinders of enormous size orbiting Saturn, which are spewing out what he calls 'streamers'. He claims that these are plasma streamers, although he does not appear to have any idea as to why this is being done.

His idea of strange cylindrical craft emitting streamers of plasma arose from a chance personal observation that he made of such a craft in the atmosphere off the coast of California in September 1971, which was also viewed by his wife from a separate location. By triangulating their observations, he and his wife were able to place the 'UFO' at a distance of sixty miles off the coast of Monterey Bay. Bergrun calls these craft 'EMVs', for electromagnetic vehicles. Although this all sounds very fanciful, I was told in 2015 by a friend who knows top scientists and officials at DARPA, the Defence Advanced Research Projects Agency of the US Government (by far the most advanced 'weird science' organization or agency in America, which developed stealth aircraft, among other things), that the DARPA people not only know of but accept and worry about the intrusive cylindrical craft, which they accept are 'not of this Earth'.

They may come from 'another world' 'another dimension', 'the future', or whatever you like, but they do not come from any human civilization of the present day. Some of the cylindrical craft can be of such enormous size that no contemporary civilization on Earth would be capable of constructing anything so huge, even if it were sitting on the ground. It is apparently known and accepted by the scientists at DARPA that these craft have intimate connections with a highly advanced plasma science that is far beyond our present understanding or capacities. Apparently they also believe that they are not manned by living beings, but by hyper-intelligent robots that come from 'somewhere else', but no one knows where.

No living entities could accomplish these feats, as the gigantic tasks involved could only be undertaken by robots over extremely long periods of time, far exceeding any conceivable human or other organic lifespans. Just in case anybody thinks that constructing spaceships by robots is far-fetched, I can point out that we humans are already doing it. The London *Sunday Times* published on 15 August 2021 (page 9 in the 'Money' section) an article entitled 'Backing the spaceships being built by robots', which reported that the American company Relativity Space is building 'its "Stargate" factory (which) will build rockets through 3D printing' and assemble by robots the more than 100,000 parts that must go into each spaceship.

I mention all of this about Bergrun's ideas in passing without personal comment, because it is not the subject of this book. However, it appears that the urgent impetus behind much of the advanced plasma research going on at the moment comes from DARPA, who are desperate to try to understand the intruders. (Another reason is that stealth aircraft can be much improved if Bose-

- Einstein condensate technology can be mastered for the exterior skins of the planes. That relies upon extraordinary discoveries which have been made since 2010. Although this relates to our subject, it has been necessary to remove my account of it from the book for reasons of space. The technology is named after Satyendra Nath Bose (an Indian) and Albert Einstein. Information about its basic principles can be found on the web.)

Husein-Zade, Boris Aleksandrovich Klumov, and Sergey Vladimirovich Vladimirov, 'From Plasma Crystals and Helical Structures towards Inorganic Living Matter', in *New Journal of Physics*, Vol. 9, 2007, pp. 263 ff.
- 8. Dietmar Block and André Melzer, 'Imaging Diagnosis in Dusty Plasmas', in Michael Bonitz, Norman Horing, and Patrick Ludwig (eds.), *Introduction to Complex Plasmas*, Springer, Berlin, 2010, p. 136.
- 9. Fred Hoyle, *The Black Cloud*, Heinemann, London, 1957. This novel concerns a large black cloud in outer space, which possesses a high degree of intelligence. This science fiction novel caused a considerable sensation with the public when it was published, and established Fred Hoyle as one of the world's major science fiction authors. Such was the popular clamour for more such intelligent science fiction from Hoyle that he was approached by the BBC and, with the BBC producer John Elliot, wrote a famous TV drama series called *A for Andromeda*, broadcast in 1961, which was followed by *The Andromeda Breakthrough* in 1962. These caught the popular imagination, and people still talk about them all these many decades later. *A for Andromeda* was made into a feature film in 2006. *The Black Cloud* has never been filmed.

# **Chapter 13: The Mysterious Case of the Dirty Gas**

- 1. The first one I saw (unsigned) was in the London *Daily Telegraph*, 23 September 2015, and was entitled 'Why We Are All Under a Cloud (of Germs, That Is)'. On the same day, the BBC News website carried an article by James Gallagher, the BBC's Health Editor, entitled 'Everyone Has a "Microbial Cloud". Gallagher speculated: 'So should we all take extra showers?' But a British bacteriologist whom he consulted told him 'It wouldn't help.' Adam Altricher, a researcher working with Meadow, told him on the phone: 'We need to understand that we're not sterile and this is something completely natural and healthy.'
- 2. James Meadow, Adam E. Altrichter, Ashley C. Bateman, Jason Stenson, G.Z. Brown, Jessica L. Green, and Brendan J.M. Bohannon, 'Humans Differ in Their Personal Microbial Cloud', *PeerJ*, 22 September 2015, at <a href="https://doi.org">https://doi.org</a> (the International DOI Federation, or IDF).

- 6. David B. Geselowitz, 'Model Studies of Electric and Magnetic Fields of the Heart', in *Journal of the Franklin Institute*, Vol. 296, No. 6, December 1973, pp. 379–91. He then went on to become a world expert on this subject.

- 7. Freeman Widener Cope, 'Activation Energies of Acceleration and Hypoxia Stress', Report No. 5 for the Bureau of Medicine and Surgery, Naval Air Development Center, Aerospace Medical Research Department, 2 July 1970, declassified sometime subsequent to 1979.
- 8. W. Edward Mann, *Orgone, Reich & Eros: Wilhelm Reich's Theory of Life Energy*, Simon and Schuster, New York, 1973, pp. 38–9.
- 9. David Talbot, *The Devil's Chessboard: Allen Dulles, the CIA, and the Rise of America's Secret Government*, Harper Collins, London, 2015, p. 56. So eager was Dulles to reach an accommodation with the Nazis before the Second World War ended that he initiated his own secret peace plan entitled Operation Sunrise, falsely claiming that he was a personal representative and close friend of President Roosevelt. In pursuit of his plan, he secretly negotiated a peace deal, entirely without authority, with SS General Karl Wolff, who had previously been Himmler's Chief of Staff (Himmler was so fond of Wolff that he called him 'Wolffie').

Wolffie was also popular with Hitler, was the principal liaison between Hitler and Himmler, and was always welcome at Hitler's dinner parties. The Nazi High Command used to cite Wolffie as 'the ideal Aryan'. As an old man, Wolffie recalled: 'Hitler wanted to have me nearby, because he knew that he could rely on me completely. He had known me for a long time, and rather well.' Despite being directly ordered by President Roosevelt not to negotiate with Wolffie, Dulles continued his own private American foreign policy by plotting a deal with Wolffie. Wolffie was in fact negotiating a potential deal on behalf of his boss Himmler. The plan of Dulles failed, but then, as they were such chums, Dulles went on to save Wolffie's life. The sleazy details of this treasonous tale have been discovered by Talbot. See Chapter 4, 'Sunrise', commencing on p. 74.

- 10. Adam Lebor, *Tower of Basel: The Shadowy History of the Secret Bank That Runs the World*, Public Affairs, New York, 2013, passim. (See the Index for Allen Dulles, his equally pro-Nazi brother John Foster Dulles, and McKittrick.)
- 11. Talbot, op. cit., pp. 17, 617.
- 12. Wilhelm Reich, *The Mass Psychology of Fascism* (translation from the manuscript of the third enlarged edition of *Die Massenpsychologie des Fascismus*), Orgone Institute Press, Inc., New York, New York, 1946, p. 31. (The first edition of this book in German was published in 1933, the second edition in 1934. The third enlarged edition existed in German only in manuscript, and fortunately it was translated by Reich and published in English before the FBI could burn it! Presumably, however, the original German manuscript of the third edition, never published in German, was destroyed or seized by the FBI, which must have delighted America's imported Nazis.)
- 13. I once asked a man the first name of one of his former colleagues with whom he had jointly written a now declassified article. That is because for my bibliographies I don't like using first initials, but always like to know the first names of scientists. He denied ever knowing him, despite the fact that I have a copy of an article describing their joint work together. That shows you the fear scientists have, which is so great that they dare not admit that they have even met the people with whom they worked for years.
- 14. Freeman Widener Cope, 'Man in a Gas of Tachyon Magneto-electric Dipoles A New Hypothesis', Parts 1, 2, 3, and 4, appearing sequentially in *Physiological Chemistry & Physics*, Vols. 10 and 11 for 1978 and 1979. Part I is Vol. 10, 1978, pp. 535–40; Part 2 is Vol. 10, 1978, pp. 541–5; Part 3 is Vol. 10, 1978, pp. 547–55; Part 4 is Vol. 11, 1979, pp. 87–91. Cope's fifth article was separate and entitled 'Delocalized Clouds (Wavefunctions) of Polymerized Tachyon Magnetoelectric Monopoles', in the same journal, Vol. 11, 1979, pp. 175–9. It does not appear that he published anything further on the subject, and he died young in 1983. In the notes I shall refer to Cope, Parts 1 to 5. This quotation is from Part 1, p. 535.
- 15. Baron (Freiherr) Karl von Reichenbach, Researches on Magnetism, Electricity, Heat, Light, Crystallization, and Chemical Attraction in Their Relations to The Vital Force, Parts I and II

- (including the second edition of the First Part, corrected and improved), edited and translated with a preface, notes, and appendix by William Gregory, Taylor, Walton and Maberly, London, 1850
- 16. Another strange cosmic force of 'vital magnetism' was proposed in 1871 by the supernatural novelist Edward Bulwer-Lytton, in his novel *The Coming Race*, though Cope does not mention this. Bulwer-Lytton appears to have taken his idea of vril from Reichenbach's odic force. Strangely enough, some of the occult Nazis seriously believed in the actual existence of vril, despite its having appeared in an admitted work of fiction. They apparently believed that Bulwer-Lytton knew of its true existence and revealed it in intentionally disguised form by proposing it within the context of a novel.
- 17. Cope, Part 3, op. cit., p. 547.
- 18. Paul Dirac, 'Quantized Singularities in the Electromagnetic Field' in: *Proceedings of the Royal Society of London, Series A*, Vol. CXXXIII, London, October 1931, pp. 60–72. On page 71 of this paper, Dirac says: 'The object of this paper is to show that quantum mechanics does not really preclude the existence of isolated magnetic poles. On the contrary, the present formalism of quantum mechanics, when developed naturally without the imposition of arbitrary restrictions, leads inevitably to wave equations whose only physical interpretation is the motion of an electron in the field of a single [magnetic] pole.'
- 19. Dirac expanded and refined these ideas seventeen years later in 1948: Paul Dirac, 'The Theory of Magnetic Poles' in: *The Physical Review*, Second Series, Vol. 74, No. 7, 1 October 1948, pp. 817–30. In this paper, Dirac more emphatically than ever suggested that magnetic monopoles must exist. In the various discussions of magnetic monopoles that I have encountered, Dirac's paper of 1931 tends to be cited, but I do not recall anyone citing his follow-up paper of 1948, which expands the theory considerably. (Perhaps Lochak mentioned it, although I do not recall that.)

In the 1948 paper, of which I have an original copy, Dirac says: 'In 1931 I gave a primitive theory which described the action of a pole in the field of a charged particle whose motion is given, or the motion of a charged particle in the field of a pole whose motion is given. The present paper sets up a general theory of charged particles and poles in interaction through the medium of the electromagnetic field. The idea which makes this generalization possible consists in supposing each pole to be at the end of an unobservable string, which is the line along which the electromagnetic potentials are singular, and introducing dynamic coordinates and momenta to describe the motion of the strings. The whole theory then comes out by the application of standard methods ... The theory developed in the present paper is essentially symmetrical between electric charges and magnetic poles.'

This brilliant paper by Dirac seems largely to have escaped notice by his fellow physicists. Dirac's idea of a 'string' is also very suggestive. My own instinct is not to think of the string as being straight, but on the contrary that it must exist either in helical form or in toroidal form (i.e., existing on one or other of the two circularities of a toroidal surface, unless linking the two). In fact, to say that a particle is a 'string' is effectively to say that it is a filament. And filaments like to spiral helically. And because they also like to spiral as double-helixes, this might apply to those paired electrons known as 'Cooper Pairs', which are discussed later. These matters require deeper consideration than an aside in a footnote, however.

# **Chapter 15: How Our Bodies Emit Light**

- 1. Roeland van Wijk, *Light in Shaping Life: Biophotons in Biology and Medicine*, Meluna, Geldermalsen, The Netherlands, 2014, p. 355.
- 2. It is for this reason that I have registered a website to preserve as much as possible of the scientific papers in all languages on the subject, and thousands of pages have already been scanned and turned into pdfs for download. All the publications in German and Russian, as well as the working notebooks, of Alexandr Gurvich (discoverer of biophotons) will be available for public download, because they are out of copyright. However, most of the material will only be accessible to a closed registered group because of copyright complications involving journals and publishers. But at least the archives will be preserved for posterity in this way. The most helpful person in making material available has been my friend Marco Bischof, whose enthusiasm is exceeded only by his profound knowledge.
- 3. Van Wijk, op. cit.

- 5. Strange and somewhat embarrassing support came from one of Himmler's S.S. researchers, Otto Rahn (1904–1939). Anyone interested in the bizarre career of Rahn can read about it on Wikipedia, but Wikipedia does not mention the important book by Rahn relating to biophotons, *Invisible Radiations of Organisms* (Berlin, 1936, reprinted 1944), which suggested that aging was due to the slowing and cessation of the emission of ultra-violet radiation within the body, a dubious idea. Rahn also pointed out, however, that the healing of wounds took place because of UV (ultra-violet) emissions, and that irregularities of these emissions were implicated in cancer (which we now know to be true). Rahn tried to leave the employ of Himmler, and was apparently murdered in consequence. Many of his publications were cranky, and it is thus ironical that no attention has been called to the one that was actually useful.

# Chapter 16: The 'Death Flash' and the 'Life Flash'

- 1. Janusz Sławinski, 'Electromagnetic Radiation and the Afterlife', in *Journal of Near-Death Studies*, Vol. 6, Part 2, winter 1987, pp. 79–94.
- 2. Because I am interested in French literature (and indeed my wife Olivia and I have sponsored numerous translations of modern French literary classics into English), I have read widely in twentieth-century French fiction. One of the most congenial authors to me is the passionate French Anglophile, André Maurois. By chance, browsing in a bookshop some years ago, I came across a little book by him containing a novella bearing the strange title *The Weigher of Souls*, which is a direct translation of its original French title *Le Peseur d'Ames*. I now possess a first edition of this novella signed by Maurois, whose signature by the way is practically microscopic, so that you almost need a magnifying glass to read it. (He must have been a very modest person!)

The book was published originally in 1931 in Paris in several simultaneous editions on different kinds of paper, and later in the same year in a version atmospherically illustrated by Francis Picabia. (I have been fortunate to acquire Maurois's own personal copy with his bookplate of this special edition. André Maurois, *Le Peseur d'Ames*, with frontispiece and eight illustrations by Francis Picabia, Antoine Roche, Paris, 1931, unnumbered author's own *exemplaire sur japon impérial*; the bookplate says 'Ex Libris Simone Andre Maurois'. Simone de Caillevet was the second wife of Maurois and died in 1968, a year after he did. It seems that they shared their bookplate.)

Also in the same year, the English translation appeared in America in the popular highbrow magazine *Scribner's*, for March 1931. That issue announces prominently on the cover: 'André Maurois's New Novel "The Weigher of Souls" Complete in this Issue.' I also have its first edition in English as a book, published in the same year by D. Appleton & Company in association with Scribner's, in both London and New York. Despite the prominence with which this title was thus originally launched, it seems to have attracted only limited attention, which I also find curious. The French were always somewhat uncomfortable about Maurois, because he liked the English too much, and also because he was a Jew (Maurois was his pen name, and his real surname was Herzog).

André Maurois (1885–1967), the author of *The Weigher of Souls*.

Today, if you ask someone in France about Maurois, the person will either look blank or pretend to look blank. After all, grumbling about the barbaric nature of les ros bifs ('the roast beefs') who live across the English Channel is one of the favourite hobbies of the French, and one that they do not wish to see compromised by too much Anglophilia. Hence, it has been convenient largely to 'forget about' both Maurois and his contemporary French Anglophile, the novelist Valéry Larbaud, who translated James Joyce's *Ulysses* into French.

Maurois met with tremendous literary success in Britain with his series of Colonel Bramble novels, light-hearted and comic accounts of the British soldiers during the First World War, written in a tone of great affection. Maurois had been a French military liaison officer with a British regiment just behind the Front for most of the war. He was thus unusual in that he was a French officer who spent the war in the company of British officers rather than French ones.

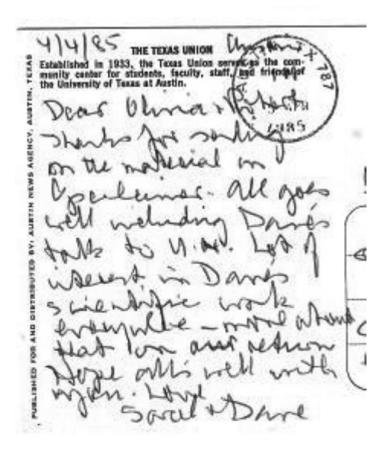

- 3. Wilfried-René Chettéoui (note that Wilfried is misspelled Wifried in this source), 'The Process of Birth and Reincarnation Theory', in the Proceedings and Abstracts of the 6th International Conference on Psychotronic Research held at Zagreb, Yugoslavia, 13–16 November 1986, published by the Society for Natural Sciences at Zagreb in 1987 (though no publication date is given), the volume apparently being edited by Zdenek Rejdák, p. 314. (The main title of this book is in Czech, with the English title beneath.)
- 4. Duncan MacDougall, 'Hypothesis concerning Soul Substance together with Experimental Evidence of the Existence of Such a Substance', in *Journal of the American Society for Psychical Research*, 1 (1), 1907, p. 237; also 'The Soul: Hypothesis concerning Soul Substance together with Experimental Evidence of the Existence of Such Substance', in *American Medicine*, 2, April 1907, pp. 240–3. A popular report of this appeared in *The New York Times*, entitled 'Soul Has

- Weight, Physician Thinks', 11 March 1907; this appeared before MacDougall's own articles had even been published later that year. See the Wikipedia entry '21 Grams Experiment'. Apparently, MacDougall's experiments of 1907 have never been repeated.
- 5. This account is to be found on the website: <a href="www.thebiggeststudy.blogspot.com/2012/12/the-mist-at-death.html">www.thebiggeststudy.blogspot.com/2012/12/the-mist-at-death.html</a>.

#### **Chapter 17: Our Plasma Selves**

- 1. Aleksandr Samuilovich Presman, *Electromagnetic Fields and Life*, translated by F.L. Sinclair and edited by Frank A. Brown, Plenum Press, New York and London, 1970. The original Russian edition, *Elektromagnitnye Polya I Zhivaya Priroda*, was published by Nauka ['Science'] Press of Moscow in 1968.
- 2. Ibid., pp. 5–6.
- 3. Robert Temple, *The Genius of China: 3000 Years of Science Discovery & Invention*, with Foreword by Joseph Needham, Andre Deutsch, London, 2007.
- 4. Paul Alfred Weiss, *Principles of Development: A Text in Experimental Embryology*, Henry Holt and Company, New York, 1939. Paul Alfred Weiss should not be confused with Paul Weiss the philosopher. Later publications by Weiss, not cited by Presman, include *Dynamics of Development: Experiments and Inferences*, Academic Press, New York and London, 1968, and *The Science of Life: The Living System A System for Living*, Futura Publishing Company, Mount Kisco, New York, 1973.
- 5. Presman, op. cit., p. 249.
- 6. Robert Temple, 'David Bohm', in *New Scientist*, London, 11 November 1982, pp. 361–6. A whole line of type was left out, and other errors appeared in the published article. I urge people interested in David Bohm to download for free a pdf of this article with my hand corrections, including the missing line of type. It may be obtained from my entry on <a href="www.researchgate.net">www.researchgate.net</a>. Just type in my name, click on my publications, and scroll down the chronological list until you get to 1982, and there it is.
- 7. David Bohm, *Quantum Theory*, Prentice-Hall Inc., New York, 1951. David signed my copy of the original edition.
- 8. Here is a scan of a postcard that Saral sent to us, to show the nature of the friendship, sent from America on their trip there in the spring of 1985. It reads: 'Dear Olivia & Robert, Thanks for sending on the material on Oppenheimer. All goes well including Dave's talk to U.N. Lots of interest in Dave's scientific work everywhere more about that on our return. Hope all's well with you. Love Saral & Dave.'

- 9. Paavo Pylkkänen, *Mind, Matter and Active Information: The Relevance of David Bohm's Interpretation of Quantum Theory to Cognitive Science*, Reports from the Department of Philosophy, No. 2, University of Helsinki, Finland, 1992, p. 66.
- 10. David Bohm, 'A Suggested Interpretation of the Quantum Theory in Terms of "Hidden Variables' Part I (14 pages), 15 January, pp. 166–79, and Part II (14 pages), 15 January, pp. 180–93, in *Physical Review*, American Physical Society, Vol. 85, Second Series, 1 January–15 March 1952. At the time of writing he was still based at the Palmer Physical Laboratory at Princeton, and his papers are marked received on 5 July 1951, but a note says: 'Now at Universidade de Sao Paolo, Faculdade de Filosofia, Ciencias e Letras, Sao Paolo, Brazil. (I have an original bound volume containing these papers.) So between the time of submission and publication, Bohm had had to flee the country and seek refuge in the philosophy department of a university in Brazil, where he did not even have a science position.
- 11. I need to explain to the reader that the aspect of David Bohm's thinking that we are dealing with here is a later outgrowth of his main ideas. I have discussed the theories of Louis de Broglie and David's impact on them at some length here: Robert Temple, 'Is Particle Mass a Function of Degrees of Freedom?', in *Journal of Cosmology*, Vol. 26, No. 3, 2017, pp. 13995–14090. Downloadable as a pdf from my entry on <a href="https://www.researchgate.net">www.researchgate.net</a>, under the date 2017.
- 12. This point relates to one of my own major points made in my lengthy 2017 paper (just mentioned), regarding the crucial importance of amplification in every aspect of science, and where I said for instance: 'Amplification in electronics turns a weak signal into a strong signal, and it does not necessarily require an amplifier, such as we in our macroscopic world employ, because it apparently occurs spontaneously at the ultra-weak level in Nature in electron streams under the influence of magnetism.' See page 20 and passim in my paper.

- 17. Pylkkänen, 1992, op. cit., p. 91.
- 18. As is usual with Wikipedia, Rupert's entry on it is riddled with vitriol and insults against him, Wikipedia being apparently partial to the most intensely partisan and extreme attacks on people whose names are on whatever black list it is that they consult. When people like Rupert attack the stupidities and idiocies of Establishment ideas, the Establishment strikes back. Most of the famous scientists mentioned in this book were savagely attacked during their lifetimes because they thought for themselves.

Rupert told me that when he was a student at Cambridge, he was told in lectures that there was a man named Peter Mitchell who was crazy and none of the students should pay any attention to his ideas if they should ever come across them. That is the same Peter Mitchell, my good friend whom I have mentioned before, who won the Nobel Prize after a lifetime of being called crazy and libelled even in lectures given to students at Cambridge such as Rupert. Cambridge is also the place from which Sir Fred Hoyle was driven by relentless and vicious personal attacks led by a cabal of snobbish enemies who, among other things, did not like Fred's Yorkshire accent and his lowly origins. The world of learning can be more poisonous even than the world of politics.

- 20. For decades I have said to friends that the reason why I can walk into a library of three million books on open shelves (such as the one at my university when I was in my teens), go down an apparently random aisle, reach up to an apparently random shelf, and without looking at it pick the book I need and open it to the page I require is that I am able 'to see directly into Information Space'. Since I have been doing this all my life, when I speak of Information Space and 'the Universe as Information', my natural scepticism dissolves into something approaching certainty. In other words, even though I do not believe in belief, this I not only believe but know.

- 26. Robert Temple, *Netherworld*, Century, London, 2002. The relevant section of this book is the final chapter, entitled 'Higher-Order Events'; this chapter has been extracted from the book and may be downloaded from my <a href="www.researchgate.net">www.researchgate.net</a> entry under the date of 2002 (as the entries on the website are chronological).
- 27. Ibid., p. 354 (UK edition). I might add for those interested in the prehistories of ideas that the main ancient proponent of voids occurring in matter was the philosopher Strato of Lampsacus (335 BC–269 BC). He was the second successor of Aristotle as the Head of the Lyceum, though he could not have known him because he was only a boy when Aristotle died. His works are lost except for fragments and testimonia, which have been gathered and translated in the volume:

Marie-Laurence Desclos and William W. Fortenbaugh, *Strato of Lampsacus: Text, Translation, and Discussion*, Vol. XVI of the series Rutgers University Studies in Classical Humanities, Transaction Publishers, New Brunswick, New Jersey, USA, 2011. The fragments relating to void (*kenon* in Greek) are found on pages 70–83.

Most were preserved by Simplicius, who disagreed with him, in his Commentary on Aristotle's *Physics*. On page 79 we find Simplicius saying this: 'Strato of Lampsacus tries to show that void divides the whole of body, so that it is not continuous ...' And on the same page and following we find Hero in his *Pneumatica* saying that there are voids in matter. And he adds: 'It is also clear ... that there are voids in water ... there are many other demonstrations of the nature of the void ... every body is composed of small bodily particles, between which there are scattered voids which are smaller than the particles ...'

Part of Hero's extended discussion is directly drawn from Strato. This volume concerning Strato is part of an extended series of collections of the fragments and testimonia of the Peripatetic philosophers. I am very fortunate to have enjoyed the jolly company and warm friendship of Bill Fortenbaugh, who has been a genuine culture hero and shining light in the world of classical studies in our time.

Vadim Nikolaevich Tsytovich (aka Cytovič), Sergey Vladimirovich Vladimirov, and Gregor Eugen Morfill, 'Size of Dust Voids as a Function of the Power Input in Dusty Plasmas', in *Journal of Experimental and Theoretical Physics*, Vol. 102, 2006, pp. 334–41. (The attentive reader will notice that Tsytovich is the man who has been quoted by me as suggesting that complex dusty plasmas can become life forms.)
- 29. Osamu Ishihara and Noriyoshi Sato, 'Attractive Force on Like Charges in a Complex Plasma', in *Physics of Plasmas*, Vol. 12, 070705 (2005). There is a drawing of a plasma void as Figure 2 in that paper. This work was done for the United States Air Force Research Agency.
- 30. Osamu Ishihara, 'Report on Study of Cryogenic Complex Plasma', report date 5 November 2008, submitted to the funding agency, the Asian Office of Aerospace Research and Development (AOARD), an extension in Asia of the US Air Force Research Agency, reporting to the Air Force Research Laboratory at Kirtland Air Force Base near Albuquerque, New Mexico. This Report appears in a collection of material entitled 'Charged Colloidal Structures in Plasmas', declassified and released by the US Department of Defense, no date.
- 31. Xiao-Qiong Wang, et al., 'Evidence of an Atomic Chiral Superfluid with Topological Excitations', in *Nature*, Vol. 596, No. 7871, 12 August 2021, pp. 227–31.

# **Chapter 18: Wrapping Up the Universe**

1. Robert Temple, *Open to Suggestion*, The Aquarian Press, Wellingborough, Northamptonshire, England, 1989. The relevant discussion constitutes the final chapter in the book pp. 361–458. The ideas which I propounded in that chapter were praised by Professor Ernest R. ('Jack') Hilgard, Former President of the American Psychological Association, and also by Professor John Taylor, who told me that he had adopted many of my concepts and suggestions for his neural network team at Kings College London, and that I had therefore contributed towards an advance in neural network science, for which he thanked me.

The book's publication in the USA was blocked by the CIA, as I was informed by no less than eight American publishers who had been personally visited and warned not to publish the book. This had the indirect result of giving the UK an advantage in neural network science, since no one in America was able to obtain the book (no international Amazon sales existed then).

2. This paper, entitled 'Early Einstein Completed', was published in June 2019 and may be downloaded from my <a href="https://www.researchgate.net">www.researchgate.net</a> entry, by looking for that date, as the entries are chronological.

#### **Abstract**

Recent astronomical observations combined with dynamical simulations have led to a possible confirmation of the existence of the much disputed stable dust clouds (Kordylewski Dust Clouds) at the Lagrange libration points of the Earth-Moon system. The new data leads to an estimate of the size of the cloud at L5 as well as of the average radii of the scattering/polarizing dust particles in the cloud's interior. The diameter of the cloud is somewhat less than 3 times the Earth's diameter, and the

average grain radius is estimated at  $\sim 3 \times 10^{-5}$  cm, consistent with bacterial-type cells, with a mean separation of less than 1 cm. Such grains, most likely elongated on the average (rod-like bacteria), and photoelectrically charged to a few eV, would acquire a spin through collisions with gas atoms and thus could act as emitters and absorbers of longwave electromagnetic radiation. We speculate that the entire Kordylewski Dust Cloud comprised of such particles has the potential to acquire electromagnetic connectivity with an information storage/processing capacity akin to a form of intelligence.

#### 1. Introduction

The existence of large stable dust clouds at the Lagrange libration points L4 and L5 of the Earth-Moon system appears to have been finally confirmed by a combination of numerical dynamical simulations and polarimetric studies (Sliz-Balogh et al, 2018, 2019). An initial tentative observation of such clouds was reported in 1961 by the Polish astronomer Kazimierz Kordylewski following

which they came to be known as Kordylewski Dust Clouds (KDC) (Kordylewski, 1961). The existence of these clouds has, however, been questioned for over 3 decades mainly because of the difficulty of interpreting minute enhancements of night sky brightness in relation to other possible causes. There were also early attempts to detect centimetre to metre-sized bolides in the putative KD clouds using RADAR with negative results and these have been widely considered as disproof of their existence (Roosen and Wolff, 1969; see also, Hou et al, 2015). It is clearly desirable to repeat the earlier RADAR observations and also possibly deploy LiDAR (*Light Detection And Ranging*) measurements to look for returns from smaller particles to establish their presence.

In two recent publications Sliz-Balogh et al (2018, 2019) focussed their attention on the particular dust cloud (KDC) at the L5 point of the Earth-Moon system using sensitive polarimetric techniques. They found clear evidence that a cloud of submicron dust does indeed exist there through examination of polarized scattered light that varied with time (Sliz-Balogh et al, 2019). The cloud appeared to be "dynamic" and contained within it smaller dust clouds, perhaps displaying a cellular-like structure. Although evidence was cited to support the presence ferric and silicate particles we cannot rule out, on the basis of available evidence, the presence of a dominant contribution of carbonaceous or organic grains, as indeed is known to be predominantly present in the interplanetary zodiacal cloud, in cometary dust, as well as the interstellar medium (Hoyle and Wickramasinghe, 2000; Steele et al, 2018).

Further definitive confirmation of the existence of KDC's is clearly desirable and we hope this will be done. It will also be important to unravel the fine structure within clouds, including their internal dynamic properties, but these cannot easily be studied from Earth. Such studies will require investigation by dedicated satellite and astronautical studies at some future date.

In this article we explore some interesting features of these dust clouds particularly if they are comprised of particles that include a significant biological component.

# 2. Inferred Properties of the L5 KDC

The stability and existence of a KDC at the L5 point has been modelled using 3-D by dynamical simulations, and its actual existence confirmed by means of polarimetric observations of scattered light (Sliz-Balogh et al, 2018, 2019). The inferred angular extent of the scattering dust cloud at L5 has been estimated at between  $\theta$ =6 and 7 degrees. At the known distance of L5,  $r = 3.84 \times 10^9$  cm, this angular extent transfers to an average cloud diameter D given by

$$D \approx \frac{\theta}{360} 2\pi r \approx 4.35 \times 10^8 \,\text{cm} \tag{1}$$

This is to be compared with the Earth's diameter of  $\sim 1.27 x 10^8$  cm.

For a spherical particle of radius a (silicate grain or an organic grain typified for example by a bacterium) the cross-section for scattering of sunlight is

$$C_{sca} \cong Q_{sca}\pi a^2$$
 (2)

with *Qsca* having a value close to 1 at optical wavelengths (eg. Wickramasinghe, 1973). For an assembly of such grains in the cloud the average mass scattering coefficient is thus

$$\kappa_{sca} \cong \frac{\pi a^2 Q_{sca}}{\frac{4}{3}\pi a^3 s} \approx \frac{3}{4as} \text{ cm}^2 \text{g}^{-1} \approx 2.5 \text{ x } 10^4 \text{ cm}^2 \text{g}^{-1}$$
 (3)

assuming  $a \sim 3 \times 10^{-5}$  cm,  $s \sim 1$  g cm<sup>-3</sup>.

For significant polarization effects to be observable (Sliz-Balogh et al, 2019) the scattering optical depth through the 4.35 x  $10^8$  cm path-length of the cloud (equation (1)) must be of order unity, say for instance,  $\tau_{sca} \approx 0.3$ . This converts to a mass density of bacterial dust  $\rho$  in the cloud given by the equation

$$0.3 \cong \aleph_{sca}D\rho \cong 1.09 \times 10^{13}\rho \tag{4}$$

with the diameter of the cloud given by (1), thus yielding a mass density

$$\rho \approx 2.75 \times 10^{-14} \text{ g cm}^{-3}$$
 (5)

The Kordykewski dust cloud at L5 on this basis has a density which is at least  $10^9$  higher than the density of the ambient interplanetary dust (Allen, 1963). Losses due to the effects of solar radiation, as well as the solar wind effects and small gravitational perturbations which occur mostly in the outermost regions of the KDC will, over long timescales, be made good by the acquisition of new dusty material from comets and the interplanetary medium. The total mass of the cloud observed by virtue of (1) and (5) is thus  $\sim 1.17 \times 10^{12}$  g.

Assuming that a typical dust particle in the cloud has the size characteristics of a bacterial spore with a particle radius  $a \sim 3 \times 10^{-5}$  cm and mass density  $\sim 1$  g cm<sup>-3</sup>, we therefore have an average *number* density of dust particles in the cloud of

$$n \approx 2.43 \text{ cm}^{-3}$$
. (6)

The mean distance between neighbouring particles is then

$$\sim n^{-1/3} \sim 0.74$$
cm! (7)

very short indeed, and yielding the possibility of inter-particle "communication" if electromagnetic signals can be exchanged. This could be made possible because the bacterial dust would be charged to a potential of a few volts due to the photoelectric effect caused by absorption of solar ultraviolet photons; and collisions with ambient gas would lead to rotation (spinning) at radio frequencies as had been discussed many years ago by Hoyle and Wickramasinghe (1970).

# 3. Emergent properties of KDC's

Spinning charged grains, particularly those in the form of elongated needles typified by bacilli, would be efficient absorbers and emitters of electromagnetic radiation. Most interestingly the total number N of such charged dust particles in a KDC (distance of < 1cm apart) would be truly vast

$$N \approx \frac{\frac{4}{3}\pi R^3}{n} \cong 2 \times 10^{26}$$
 (8)

With electromagnetic-wave emission/absorption across cloud dimensions as well as electrical connections (charge/current exchanges) between adjacent charged particles just centimetres apart, a KDC, might well be able to function as a gigantic computer/brain capable of storing and processing digital information. We are reminded in the present context of the well-attested cooperative behaviour of bacteria in a wide range of terrestrial settings (Asfahl and Schuster, 2017; Mitchell and Kogure, 2006).

A human brain has only some  $10^{11}$  brain cells, and about  $10^{15}$  synapses. A KDC (from (8)) may well have a total number of binary connections

$$\sim {}^{n}C_{2} \approx 10^{52}$$

between its constituent oscillators, so defining a super-astronomical sum total for its potential computing power. This estimate exceeds the computing power available in all human brains and indeed all other intelligent life on Earth as well by very many orders of magnitude.

Finally, we refer to a few of the remarkable features that are known to characterise dusty complex plasmas and which could also play a role in the present context (eg. Bouchoule, A., 1999; Mikikian *et al.*, 2018). The nucleation and growth of mainly siliceous dust within such plasmas have been documented in several laboratory studies. In our case, however, the dust nucleation process will be side-stepped and condensation within KDC's is likely to occur upon pre-existing interplanetary dust particles which we already argued will probably have a biological component. Thus, we could envisage a population of bacterial particles coated with semi-conducting siliceous mantles that may well have the effect of enhancing inter-particle electronic connectivity. Such speculations may sound far-fetched but they lie within a broad framework of possible outcomes based on known behaviour of complex dusty plasmas.

We might thus be tempted to view the Lagrange Dust Balls as highly structured "intelligent" systems capable of storing and processing "information". that they may have more surprising and unexpected features. Indeed, such huge stable entities which have presumably endured for astronomical timescales and have steadily grown in complexity over billions of year may display spontaneously evolved phenomena which might resemble those of the most highly complex living entities. This situation is not dissimilar to the brain-like like complexity of the "cosmic web" discussed by Ginsburg *et al.* (2019), although it is potentially even more impressive in its computational potential.

It is often said anecdotally that the human brain contains more neurons than there are observable stars in the night sky. But the human brain only fits inside a small skull. A stable dusty complex plasma ball of immense size which has possibly endured for aeons and experienced continual growth and expansion over countless millennia is in principle capable of developing something resembling a much more complex nervous system than a human brain with its average lifetime of  $\sim 10^2$  years. A complex dust cloud (KDC) which has existed for many millions of years might even have become self-aware . . . . with all that this implies. It is conceivable that Fred Hoyle's fictional Black Cloud has a reality in the context of KDC's – which of course he could not have recognised in 1957 (Fred Hoyle, 1953).

### **OBITUARIES**

# Peter Mitchell

CORRECTION: The converse tion reported in the second para-graph of yesterday's obituary of Peter Mitchell took place in 1980, not 1950 as printed.

PETER MITCHELL was one of the most brilliant and original of Britain's men of science, though be was little known outside his field until he received the Nobel Prize for Chemistry in 1978.

Mitchell was modest, perhaps excessively so, and reclusive. He told me in 1950: "I suppose that in a few years' time nobody will even remember me." And he believed that. He hated publicity of any kind and said: "I'm really worsied by having strendon drawn to make a person." Two scientists worse the property of the prop

self. He was the basis for the main character in Michael Mulkny's book Pandon's Box which dealt with the relationship of scientisty personalities to their work.

Mitchell eastirely revolutionised the science of bioenergetics by effectively standing its theory on its bread. For a time be worked at Cambridge and Edinburgh universities (where he was Reader), but most of his work was done in a private laboratory, the Glynn Research Institute, an eighteening the control of the science of the control o

and Peter's comnoisseurship of fine wines meant that meals at Glynn were always of Michelin star quality.

Also crucial to Michell's career was Dr Jennifer Moyle was his research associate from 1948 until her retirement a few years ago, who, in 35 years, "only really ever had one quarred with Peter". For 20 years Mitchell was ridicaled, and Jennifer Moyle, and which may be comply professional supporter. So vicious was the schemific opposition to the finer a reverse form of the first time a

to offer in the areas of his other interests as he had in pure science, but one lifetime is too short for such a man, and his philosophical promise tended to be known only to a few friends such as Sir Karl Popper, whom he rewered. Mitchell has been called "the Socrates restored old buildings and worked in stone as Mitchell did, and they both devoted themselves to philosophical questioning at a deeply profound level of conversation.

ing at a deeply profound level of conversation.

Peter rose far above the level of "the great man" (which, having all pomposity he could never have been) to be in the quiet of his Cornwall retreat what I can only call a great and oid soul. His nature was so kind, so gentle, so tolerant and sympathetic; he survived so cheerfully the decade, so tolerant and sympathetic; he survived so cheerfully the decade of abuse from jealous and petry colleagues without rancour in his heart or blame towards anyone. However outstanding his achievements in science, his human qualities were of a higher order still.

# **PREFACE**

Dr Joseph Needham, Fellow of the Royal Society in Britain, a famous biochemist and historian of science and an old friend of the Chinese people, devoted his later life to the study of the history of Chinese science and technology and to encouraging friendship between the British and Chinese people. From the middle of the last century, Dr Needham gave his full strength to doing a conscientious job of classifying and researching the rich ancient Chinese traditions of science and technology, and he achieved great success. Science and Civilization in China, which is about 20 million words in length, is an unprecedented contribution to the world history of science and technology. With the correct views and thoughtful insights of a Western scholar, he came to a systematic and comprehensive conclusion about the glorious achievements of ancient Chinese science and technology through this series of works. His works fully affirm the great contribution of ancient Chinese civilization to world civilization, and erect a bridge of mutual communication and understanding between the two major Eastern and Western systems. His work has exerted tremendous and profound influence in respect of enhancing the comprehensive understanding of China by other countries, facilitating the scientific and cultural exchange between East and West, and promoting research into Chinese science and technology.

Robert Temple is a British scholar who loves the Chinese people and has a deep interest in and admiration for traditional Chinese culture and scientific achievements. Through comparative study, he came to a surprising conclusion: Possibly more than half of the basic inventions and discoveries upon which the 'modern world' rests come from China. Therefore, he came to the profound realization that civilization is an inseparable entirety and that the modern technological world is a joint creation of Eastern and Western civilisations, and that both East and West should acknowledge and respect China's contribution. In order to acquaint western readers with a general knowledge of ancient Chinese science and technology, he wrote his book The Genius of China (the Chinese edition is called The Spirit of Chinese Invention: 100 World Firsts). It selected a hundred World First cases either chronologically or according to scientific criteria from the rich and varied Chinese scientific traditions and made a

concrete and concise introduction with pictures. Most of the materials are from Dr Needham's *Science and Civilization in China*, other works of Joseph Needham, and other unpublished typescripts and materials. Temple's work was praised by Dr Needham, who therefore wrote a warm Foreword for it.

The Genius of China is a book with rich content, clear expression and excellence both in pictures and text. It is scientific, knowledgeable and interesting, which is highly suitable for young people. Our new century is an era of the knowledge-based economy. The intense competition between nations is, to be exact, a competition for national quality. Our core target of deepening educational reform and advancing quality education in an all-round way is speedily cultivating the highlyqualified personnel who possess an innovative spirit and can demonstrate capability. General Secretary Jiang Zemin has stressed repeatedly that 'innovation is the spirit of a nation and the endless momentum for a nation's prosperity'. He has also said 'The Chinese nation should occupy its proper place in the field of world hightechnology'. Our young people are expected to bear firmly in mind General Secretary Jiang's instructions, undertake the mission of the times, always regard the building of the state's prosperity and the people's happiness as their duty. They should be determined to have the lofty aspirations of loving their homeland and going all out from childhood to make their country strong, to be the 'New People' (having ideals, morality, knowledge and discipline) and dedicate their wisdom and capability to their country, and to help to realize the great rejuvenation of the Chinese nation. Reading this book, young people could not only acquire a relatively clear understanding of the splendid history of science and technology of their motherland, but also draw stimulation in the course of studying and carrying on the long-standing and well-established innovative spirit and courage of the Chinese nation. Therefore The Genius of China, written by the friend of China, Robert Temple, is a good teaching material with a unique perspective to assist in quality education for young Chinese people.

### MADAME CHEN ZHILI

State Councillor of China for Education, Science, Technology and Culture

# **FOREWORD**

I should like to give a warm welcome to this book by Robert Temple. It is, in its own way, a brilliant distillation of my *Science and Civilisation in China*, published by the Cambridge University Press, a work which will be complete in some twenty-five volumes and of which fifteen have now appeared or are passing through the press.

The extraordinary inventiveness, and insight into nature, of ancient and medieval China raises two fundamental questions. First, why should they have been so far in advance of other civilizations; and second, why aren't they now centuries ahead of the rest of the world? We think it was a matter of the very different social and economic systems between China and the West, as I will explain more fully in a moment. Modern science arose only in Europe in the seventeenth century when the best method of discovery was itself discovered; but the discoveries and inventions made then and thereafter depended in so many cases on centuries of previous Chinese progress in science, technology and medicine.

Perhaps I should describe how I became involved in all this. Coming to Cambridge in 1918, intending to read medicine, I was trained primarily as a biochemist, and specialized in the connections of biochemistry with embryology, producing *Chemical Embryology* in 1931, and *Biochemistry and Morphogenesis* in 1942. But I was always interested in the history of science, and in a way Charles Singer did as much for me as Frederick Gowland Hopkins. My *History of Embryology* came out in 1934.

Three years later the laboratories in which I worked received several Chinese scientists, some intending to do research leading to the doctorate. We became great friends, and this had two effects upon me: first, I found that the better I got to know them the more exactly like my own their minds were, which raised in acute form the question of why modern science had begun only in Europe. Second, I learnt the Chinese language; and I did so as a labour of love, which is quite a different thing from going through the mill of the Oriental Studies Tripos. By the time that one of them, now long my chief collaborator, Lu Gwei-Djen, left in 1940, we had decided that 'something absolutely must be done' about the history of science, technology and medicine in traditional Chinese culture.

Then in 1942 I was asked to go to China, as an envoy from the Royal Society, and this led to my staying there 'for the duration' of the Second World War as Scientific Counsellor at the British Embassy in Chungking. Since the post involved a great deal of travelling, I had ample opportunities for learning about what had happened in Chinese history; wherever I went there was usually someone, a medical doctor, a mathematician or an engineer, who was deeply interested in how the subject had developed in his own culture, and was able to tell me what to read, what books to buy if possible, and so on. Thus I gained a remarkable orientation, which perhaps could hardly have been achieved in any other way. After the war was over I put in two years helping to build up Unesco by organizing the Division of Natural Sciences.

When I returned to Cambridge in 1948 the project of Science and Civilisation in China began in earnest, with the help of my first collaborator Wang Ching-Ning. Although I was still Sir William Dunn Reader in Biochemisty, and therefore had a good many lectures to give to the advanced students, we made good progress, and the first volume of the series came out in 1954. Looking back at it now, I feel that in a task of this sort it is very important not to know too much, but yet to be in possession of a boundless enthusiasm for the Chinese people and their achievements over the ages. Now some fifteen volumes have been published, and the whole set is expected to consist of at least twenty-five, so we have come a long way since we started.

And gradually what a cave of glittering treasures was opened up! My friends among the older generation of sinologists had thought that we should find nothing - but how wrong they were. One after another, extraordinary inventions and discoveries clearly appeared in Chinese literature, archeological evidence or pictorial witness, often, indeed generally, long preceding the parallel, or adopted, inventions and discoveries of Europe. Whether it was the array of binomial coefficients, or the standard method in interconversion of rotary and longitudinal motion, or the first of all clockwork escapements, or the ploughshare of malleable cast iron, or the beginnings of geo-botany and soil science, or cutaneous-visceral reflexes, or the finding of smallpox inoculation wherever one looked there was 'first' after 'first'.

Francis Bacon had selected three inventions, paper and printing, gunpowder, and the magnetic compass, which had done more, he thought, than any religious conviction, or any astrological influence, or any conqueror's achievements, to transform completely the modern world and mark it off from antiquity and the Middle Ages. He regarded the origins of these inventions as 'obscure and inglorious' and he died without ever knowing that all of them were Chinese. We have done our best to put this record straight.

Chauvinistic Westerners, of course, always try to minimize the indebtedness of Europe to China in antiquity and the Middle Ages, but often the circumstantial evidence is compelling. For example, the first blast furnaces for cast iron, now known to be Scandinavian of the late eighth century AD, are of closely similar form to those of the previous century in China; while as late as the seventeenth century AD the magnetic compasses of surveyors and astronomers pointed south, not north, just as the compasses of China had always done. In many cases, however, we cannot as yet detect the capillary channels through which knowledge was conveyed from East to West. Nevertheless we have always adopted the very reasonable assumption that the longer the time elapsing between the appearance of a discovery or invention in one part of the world, and its appearance later on in some other part of the world far away, the less likely is it that the new thing was independently invented or discovered.

But all these things being agreed, a formidable question then presents itself. If the Chinese were so advanced in antiquity and the Middle Ages, how was it that the Scientific Revolution, the coming of modern science into the world, happened only in Europe? This is what we call the 'sixty-four thousand dollar question', and it may be remembered that it was precisely this problem which presented itself to me so forcefully when I first met the Chinese scientists who came to Cambridge in 1937. The fact is that in the seventeenth century we have to face a package deal; the Scientific Revolution was accompanied both by the Protestant Reformation and by the rise of capitalism, the ascendancy of the entrepreneurial bourgeoisie. Distinctively modern science, which then developed, was a mathematization of hypotheses about nature, combined with relentless experimentation. The sciences of all the ancient and medieval worlds had had an indelibly ethnic stamp, but now nature was addressed for the first time in a universal and international language, the precise and quantitative idiom of mathematics, a tongue which every man and

woman, irrespective of colour, creed or race, can use and master if given the proper training. And to the technique of experiment the same applies. It was like the merchant's universal standard of value. How one looks at the primary causative factor in all this depends on one's own background; if one is a theologian one probably thinks that the liberation of the Reformation was responsible, if one is an old-fashioned scientist, one naturally thinks that the scientific movement occurred first and powered all the others, and if one is a Marxist, one certainly thinks that the economic and social changes bear the main responsibility.

One factor which must have great relevance here is the undeniable circumstance that the feudalism of Europe and China were fundamentally different. European feudalism was military-aristocratic: the peasantry were governed by the knights in their manors, and they in turn were subject to the barons in their castles, while the king in his palace ruled over all. In time of war he needed the help of the lower ranks in the feudal hierarchy who were bound to rally to him with stated numbers of men-at-arms. How different was the feudalism of China, long very justifiably described as bureaucratic. From the time of the first emperor, Ch'in Shih Huang Ti, onwards (third century BC), the old hereditary feudal houses were gradually attacked and destroyed, while the king or emperor (as he soon became) governed by the aid of an enormous bureaucracy, a civil service unimaginable in extent and degree of organization to the petty kingdoms of Europe. Modern research is showing that the bureaucratic organization of China in its earlier stages strongly helped science to grow; only in its later ones did it forcibly inhibit further growth, and in particular prevented a break-through which has occurred in Europe. For example, no other country in the world at the beginning of the eighth century AD could have set up a meridian arc survey stretching from south to north some 2500 miles. Nor could it have mounted an expedition at that time to go and observe the stars of the southern hemisphere to within 20° of the south celestial pole. Nor indeed would it have wanted to.

It may well be that a similar pattern will appear in the future when the history of science, technology and medicine, for all the great classical literary cultures, such as India or Sri Lanka, comes to be written and gathered in. Europe has entered into their inheritance, producing an ecumenical universal science and technology valid for every man and woman on the face of the earth. One can only hope that the shortcomings of the distinctively European traditions in other matters will not debauch the non-European civilizations. For example, the sciences of China and of Islam never dreamed of divorcing science from ethics, but when at the Scientific Revolution the final cause of Aristotle was done away with, and ethics chased out of science, things became very different, and more menacing. This was good in so far as it clarified and discriminated between the great forms of human experience, but very bad and dangerous when it opened the way for evil men to use the great discoveries of modern science and activities disastrous for humanity. Science needs to be

lived alongside religion, philosophy, history and esthetic experience; alone it can lead to great harm. All we can do today is to hope and pray that the unbelievably dangerous powers of atomic weapons, which have been put into the hands of human beings by the development of modern science, will remain under control by responsible men, and that maniacs will not release upon mankind powers that could extinguish not only mankind, but all life on earth.

JOSEPH NEEDHAM

# THE WEST'S DEBT TO CHINA

One of the greatest untold secrets of history is that the 'modern world' in which we live is a unique synthesis of Chinese and Western ingredients. Possibly more than half of the basic inventions and discoveries upon which the 'modern world' rests come from China. And yet few people know this. Why?

The Chinese themselves are as ignorant of this fact as Westerners. From the seventeenth century, the Chinese became increasingly dazzled by European technological expertise, having experienced a period of amnesia regarding their own achievements. When the Chinese were shown a mechanical clock by Jesuit missionaries, they were awestruck, forgetting that it was they who had invented mechanical clocks in the first place!

It is just as much a surprise for the Chinese as for Westerners to realize that *modern* agriculture, *modern* shipping, the *modern* oil industry, *modern* astronomical observatories, *modern* music, decimal mathematics, paper money, umbrellas, fishing reels, wheelbarrows, multi-stage rockets, guns, underwater mines, poison gas, parachutes, hot-air balloons, manned flight, brandy, whisky, the game of chess, printing, and even the essential design of the steam engine, all came from China.

Without the importation from China of nautical and navigational improvements such as ships' rudders, the compass and multiple masts, the great European Voyages of Discovery could never have been undertaken. Columbus would not have sailed to America, and Europeans would never have established colonial empires.

Without the importation from China of the stirrup, to enable them to stay on horseback, knights of old would

never have ridden in their shining armour to aid damsels in distress; there would have been no Age of Chivalry. And without the importation from China of guns and gunpowder, the knights would not have been knocked from their horses by bullets which pierced the armour, bringing the Age of Chivalry to an end.

Without the importation from China of paper and printing, Europe would have continued for much longer to copy books by hand. Literacy would not have become so widespread. Johannes Gutenberg did *not* invent movable type. It was invented in China. William Harvey did *not* discover the circulation of the blood in the body. It was discovered — or rather, always assumed — in China. Isaac Newton was *not* the first to discover his First Law of Motion. It was discovered in China.

These myths and many others are shattered by our discovery of the true Chinese origins of many of the things, all around us, which we take for granted. Some of our greatest achievements turn out to have been not achievements at all, but simple borrowings. Yet there is no reason for us to feel inferior or downcast at the realization that much of the genius of mankind's advance was Chinese rather than European. For it is exciting to realize that the East and the West are not as far apart in spirit or in fact as most of us have been led, by appearances, to believe, and that the East and the West are already combined in a synthesis so powerful and so profound that it is all-pervading. Within this synthesis we live our daily lives, and from it there is no escape. The modern world is a combination of Eastern and Western ingredients which are inextricably fused. The fact that we are largely unaware of it is perhaps one of the greatest cases of historical blindness in the existence of the human race.

Why are we ignorant of this gigantic, obvious truth? The main reason is surely that the Chinese themselves lost sight of it. If the very originators of the inventions and discoveries no longer claim them, and their memory of them has faded, why should their inheritors trouble to resurrect their lost claims? Until our own time, it is questionable whether many Westerners even wanted to know the truth. It is always more satisfying to the ego to think that we have reached our present position alone and unaided, that we are the masters of all abilities and crafts.

The discovery of the truth is a result of incidents in the life of the distinguished scholar Dr Joseph Needham, author of the great work Science and Civilisation in China. In 1937, aged 37, Needham was one of the youngest Fellows of the Royal Society and a biochemist of considerable distinction at Cambridge. He had already published many books, including the definitive history of embryology. One day he met and befriended some Chinese students, including a young lady from Nanking named Lu Gwei-Djen, whose father had passed on to her his unusually profound knowledge of the history of Chinese science. Needham began to hear tales of how the Chinese had been the true discoverers of this and that important thing, and at first he could not believe it. But as he looked further into it, evidence began to come to light from Chinese texts, hastily translated by his new friends.

Needham became obsessed with the subject. Not knowing a word of Chinese, he set about learning the language. In 1942 he was sent to China as Scientific Counsellor to the British Embassy in Chungking. He was able to travel all over China, learn the language thoroughly, meet men of science, and accumulate vast quantities of priceless ancient Chinese science books. These were flown back to Britain by the Royal Air Force and today form the basis of the finest library, outside China, on the history of Chinese science, technology and medicine, at the Needham Research Institute in Cambridge. After the War, Needham was among those who 'put the "s" into Unesco', having persuaded that organization to concern itself with science as well as education and culture. He became Unesco's first Assistant Director General for the natural sciences.

In July 1946 Needham stated in a lecture to the China Society in London that: 'What is really very badly needed is a proper book on the history of science and technology in China, especially with reference to the social and economic background of Chinese life. Such a book would be by no means academic, but would have a wide bearing on the general history of thought and ideas.'

When he returned to Cambridge, where he eventually became Master of Caius College for many years, Joseph went ahead and wrote the work which he had envisaged, except that it was very academic and impenetrable to the ordinary educated reader. The result, *Science and Civilisation in China*, became a huge multi-volume project, envisaged eventually in 36 volumes (at least 24 are now available). Since Joseph's death, further volumes in the series have been issued by a number of specialist collaborators. This was a process which had begun even while Joseph was alive, with the appearance of the excellent volume on agriculture, written by a then young, intrepid sinologist, Francesca Bray, under Joseph's occasional supervision.

Gwei-Djen died tragically before Joseph, leaving him emotionally bereft, but he continued working right up to his death. One day when Gwei-Djen was still alive, I pointed to an ornate sealed gate at Caius and said to Joseph: 'What is that, and why is it so tightly shut?' He said: 'That gate is only opened at the inauguration of a new Master, or when one dies, for his funeral. One day they'll carry out me through there.' When, years later, I passed through the gate behind his coffin, I sadly recalled his comment.

Joseph never lost his early vision of a work which was 'by no means academic', as he had originally promised. He had always wanted to make his work accessible in every possible way. Therefore, when I approached him in 1984 with the suggestion that I write a popular book for the general reader based upon his half-century's labours, he agreed more readily than at that time I could understand. He and Gwei-Djen told me that they strongly approved of some things I had published about the Shang Dynasty, the I Ching and such matters, and liked the way I wrote about such abstruse subjects for the ordinary reader without sacrificing scholarly accuracy.

Although Joseph did not personally like Professor Derk Bodde, under whom I had studied Chinese philosophy, my academic background was considered acceptable because Joseph knew of Bodde's high standards. As far as Joseph and Gwei-Djen were concerned, those writings of mine proved to them that I was qualified for the task, and the only thing that remained was for Joseph to make the hard decision to relinquish the task himself, which was first announced in 1946.

I have taken certain minor liberties which must be pointed out to those readers who may consult Needham's own volumes. I have used the convention, which he avoids, of BC and AD for dates, substituting them in my quotations for his plus and minus signs. I have ironed out various passages, particularly translations from the Chinese, by eliminating Chinese words, occasional parentheses, and

specialized matter which does not concern the general reader. I have also, at Dr Needham's own suggestion, eliminated the extra letter 'h' in Chinese words which he had introduced as a substitution for the aspirate apostrophe. Hence, his *chhien* becomes *ch'ien*, etc. The system of transliteration used in this book is thus the pure Wade-Giles system. The Pinyin system which has been adopted by the Chinese government and newspapers around the world in recent years is not suitable, for it would have made reference to Needham's own volumes impossible to the non-specialist.

This book has purposely been prepared without footnotes or other scholarly accessories. Many volumes have continued to appear in the Science and Civilisation in China series, and the list of those in print should always be consulted by anyone wishing to go more deeply into certain specific subjects. The main aim of this book has been to make Needham's work accessible to the general non-specialist reader, whilst providing an overview for specialists. In preparing the book, I used many typescripts of unpublished material, discussions with Joseph and Gwei-Dien, proofs and oral and written accounts of material that had not yet been published. My account of porcelain was done entirely without the assistance of any material by Joseph, as he never wrote about that subject at all. Those collaborators, such as H. T. Huang, who were generous in helping me in my efforts have been specially acknowledged for it, for which see the Author's Acknowledgements (see pages 286-7).

In the 1946 lecture which was so prophetic of his future activities, Dr Needham went on to say:

I personally believe that all Westerners, all people belonging to the Euro-American civilization, are subconsciously inclined to congratulate themselves, feeling with some self-satisfaction that, after all, it was Europe and its extension into the Americas which developed modern science and technology. In the same way I think that all my Asian friends are subconsciously inclined to a certain anxiety about this matter, because their civilization did not, in fact, develop modern science and technology.

We need to set this matter right, from both ends. And I can think of no better single illustration of the folly of Western complacency and self-satisfaction than the lesson to be drawn from the history of agriculture. Today, a handful of Western nations have grain surpluses and feed

the world. When Asia starves, the West sends grain. We assume that Western agriculture is the very pinnacle of what is possible in the productive use of soil for the growth of food. But we should take to heart the astonishing and disturbing fact that the European agricultural revolution, which laid the basis for the Industrial Revolution, came about only because of the importation of Chinese ideas and inventions. The growing of crops in rows, intensive hoeing of weeds, the 'modern' seed drill, the iron plough, the mouldboard to turn the ploughed soil, and efficient harnesses were all imported from China. Before the arrival from China of the trace harness and collar harness. Westerners choked their horses with straps round their throats. Although ancient Italy could produce plenty of grain, it could not be trans-ported overland to Rome for lack of satisfactory harnesses. Rome depended on shipments of grain by sea from places like Egypt. As for sowing methods - probably over half of Europe's seed was wasted every year before the Chinese idea of the seed drill came to the attention of Europeans. Countless millions of farmers throughout European history broke their backs and their spirits by ploughing with ridiculously poor ploughs, while for two thousand years the Chinese were enjoying their relatively effortless method. Indeed, until two centuries ago, the West was so backward in agriculture compared to China, that the West was the Underdeveloped World in comparison to the Chinese Developed World. The tables have now turned. But for how long? And what an uncomfortable realization it is that the West owes its very ability to eat today to the adoption of Chinese inventions two centuries ago.

It would be better if the nations and the peoples of the world had a clearer understanding of each other, allowing the mental chasm between East and West to be bridged. After all they are, and have been for several centuries, intimate partners in the business of building a world civilization. The technological world of today is a product of both East and West to an extent which until recently no one had ever imagined. It is now time for the Chinese contribution to be recognized and acknowledged, by East and West alike. And, above all, let this be recognized by today's schoolchildren, who will be the generation to absorb it into their most fundamental conceptions about the world. When that happens, Chinese and Westerners will be able to look each other in the eye, knowing themselves to be true and full partners.

# Part 1

### ROW CULTIVATION AND INTENSIVE HOEING

SIXTH CENTURY BC

Growing crops in rows, and taking care to weed them thoroughly, may seem to us to be obvious and necessary processes. But they were not practised in Europe until the eighteenth century. As late as 1731, the agricultural propagandist Jethro Tull was trying to persuade European farmers to adopt what he called 'horse-hoeing husbandry', which involved growing crops in rows and hoeing them thoroughly.

The Chinese were doing this at least by the sixth century BC, and were thus a good 2200 years in advance of the West in one of the most sensible aspects of agriculture. A treatise of the third century BC, Master Lu's Spring and Antunn Annals, tells us: 'If the crops are grown in rows they will mature rapidly because they will not interfere with each other's growth. The horizontal rows must be well drawn, the vertical rows made with skill, for if the lines are straight the wind will pass gently through.'

At first, the seed was sown by hand along ridges, in a ridge-and-furrow pattern. By the first century BC at the latest, the multi-tube seed drill greatly increased the rate of sowing in rows, and with this went the intensive hoeing techniques which were pioneered by the Chinese. About the sixth or fifth century BC, cast-iron hoes were commonly available in China, after the unique advances the Chinese had made in their working of metals. A good iron hoe could be expected to last ten years for a hard-working farmer. Hoes and all agricultural tools took on a much longer life in the third century BC when the Chinese developed a malleable (non-brittle) form of cast iron. Then in about the first century BC, an improved design of hoe became widely available. Known as the swan-neck hoe, it was capable of weeding round plants without damaging them, and it had a variety of interchangeable blades. It was a splendid technological advance.

There was an ancient Chinese proverb: 'There are three inches of moisture on the end of a hoe.' And there is no doubt that careful hoeing does wonderfully conserve soil moisture. This was enormously important in north China, which is dry, often windy, and where the main crops are wheat and millet. Rice, which most Westerners think is found all over China, is mostly grown in the south, which is a quite different agricultural region.

From the *Treatise on Agriculture* of the great agriculturalist Wang Chen, published in 1313 AD, we have this colourful picture of how hand-hoeing was traditionally practised by the poorer farmers:

In the villages of the North they frequently form hoeing societies, generally of ten families. First they hoe the fields of one family which provides all the rest with food and drink, then the other families follow in turn over the ten-day period.... This is a quick and pleasant way of performing the task of hoeing, and if one family should fall ill or meet with an accident the others will help them out. The fields are free from weeds and so the harvests are always bountiful. After the autumn harvest the members of the society contribute bowls of wine and pigs' trotters for a celebratory feast.

OPPOSITE (2) The fundamental agricultural innovation of sowing (and hoeing) crops in rows has been practised in China for 2500 years, but in the West it has only been practised for one tenth of that time – before that no-one seems to have thought of it.

ABOVE (3) Intensive hoeing and row cultivation of crops originated in China in or before the sixth century BC. Here we see the technique in operation during the Han Dynasty (207 BC-220 AD).

The more prosperous farmers did not have to rely on such methods, for they had animal-drawn hoes, which were obviously much quicker. The first type seems to have been a kind of plough without a mouldboard, having two sharp, pointed shares. This was dragged along, with the shares going each side of the ridge where the crop was growing in a row. It cut the weeds away from each side of the ridge, deepened the furrows or irrigation trenches, and further banked up the soil around the roots of the plants. This implement is mentioned in Liu Hsi's book, Expositor of Names, in the second century AD. Such horse hoes came with single or double blades, which could be adapted for ridging or for more shallow hoeing. By medieval times, an improvement called a 'goose-wing' was attached to the horse hoe. This consisted of two wide flaps which further increased the deepening of the trench and the piling of the soil around the roots. Each hoeing by the horse hoe saved several hoeings by hand, though it was common for a farmer to follow behind afterwards and hand-hoe a small number of intractable weeds, by way of finishing off the job.

### THE IRON PLOUGH

SIXTH CENTURY BC

Of all the advantages which China had for centuries over the rest of the world, the greatest was perhaps the superiority of its ploughs. Nothing underlines the backwardness of the West more than the fact that for thousands of years, millions of human beings ploughed the earth in a manner which was so inefficient, so wasteful of effort, and so utterly exhausting, that this deficiency of sensible ploughing may rank as mankind's single greatest waste of time and energy.

Only the Chinese freed themselves from the tyranny of bad ploughs. And, when the Chinese plough was finally brought to Europe, it was copied and led directly to the European agricultural revolution (in combination with the growing of crops in rows and the use of the seed drill, also adopted from Chinese practice). Since the agricultural revolution of Europe is generally thought to have led to the Industrial Revolution, and to the West's superior power over the rest of the world, it is

ironic that the basis of it all came from China, and was not by any means indigenous to Europe.

The most basic and universal form of plough is called an 'ard'. It has a shallow ploughshare and makes only a slight furrow, so is sometimes preferred in areas of continual winds and thin, dry soil. Ards can still be seen at work in Spain, for example. We have pictorial representations of these implements dating back to the third millennium BC at Uruk (in present-day Iraq). They were often made entirely of wood, and thus most have not survived.

Archeological evidence for early ploughs is very scanty in China. However, archaic Chinese writings from the fourteenth century BC give evidence for ploughing.

Triangular stone ploughshares for ards have been excavated in China which go back as far as the fourth or even early fifth millennium BC. Ox-drawn ards were therefore in use in China from neolithic times. Some sixteenth-century BC bronze ploughshares for true ploughs (more exactly, turn-ploughs) have been excavated in Tonkin in Vietnam, a region with which China had trade contacts at that time. Most Chinese ploughshares, however, seem to have been of wood at this time, and consequently have not survived.

By the sixth century BC, iron ploughshares became available in China, in the form either of iron laid over wood, or of solid iron. These were the first iron ploughs in the world. They were attached in a far better way than were ard shares in the West. Greek and Roman ard shares were usually simply tied onto

the bottom of the sole with bits of rope; the two types, called 'stangle shares' and 'sleeve shares', were both flimsy and insecure compared to the Chinese ones, even when made of iron.

Improved iron supplies and casting techniques in China by the third century BC led to the design of ploughshares called kuan. At this period, the Chinese developed a malleable (non-brittle) cast iron which was far sturdier for use in agriculture. From the beginning, these kuan were advanced in their design, with a central ridge ending in a sharp point to cut the soil and wings which sloped gently up towards the centre to throw the soil off the plough and reduce friction. From about the time iron ploughs came into circulation, the bow-framed ard began to be ousted, in all but the lightest soils and windiest localities, by a heavier and more efficient square-framed turn-plough. Such proper ploughs could be used in heavier soils. These ploughs also made possible the working of much virgin land which could not have been ploughed by ards, which were too light and feeble. Heavy and waterlogged soils now became capable of proper cultivation.

By the first century BC, ploughshares attained widths of over 6 inches, and were capable of making really worthwhile furrows, scoured deep in the earth on each side of ample, wide ridges.

BELOW (4) A stone relief of the second century AD, from Yeng-tzu-shan in the southern province of Szechuan, showing a typical ancient Chinese plough drawn by an ox.

By the fourth century BC at the latest, the frame-plough was being officially promoted by government officials and literati. Nowhere else in the world at this time were there ploughs to compare with the Chinese ones. The sturdy, square frames, strong, heavy, well-designed shares and the new mouldboards were all factors well in advance of anywhere else. But perhaps of greater importance still was the use of an adjustable strut which precisely regulated the ploughing depth by altering the distance between the blade and the beam.

The new control this gave to the farmer meant that the plough could now be altered to suit whatever type of soil he encountered, from season to season, for different weather conditions and for different crops. The plough became a versatile tool indeed. For farmers, this was like going from the bow and arrow to the gun. The Romans could only adjust the depth of furrow by leaning more or less heavily on the beam – both a clumsy and an exhausting means of control. This was mostly the case all through medieval times in Europe.

By the second century BC in China, large numbers of private foundries for casting iron farming tools existed all over China. By 100 BC, the imperial

ABOVE (5) A traditional Chinese iron plough in use today. When these were introduced from China into Holland and England in the seventeenth century, they sparked the European agricultural revolution.

government had established huge state foundries in most provinces. Iron was in fairly wide general use among the populace – so iron cooking-pots were quite common for the ordinary person. There was no shortage of these advanced iron ploughs, and they were not the rare possessions of rich people, as were the early European seed drills for the first two centuries of their use.

By the first or second centuries BC, four different kinds of mouldboard were widely available for ploughs. The mouldboard is of crucial importance. It is the twisted piece of the plough, above soil level, which guides the ploughed-up earth gently to one side, where it falls in a neat ridge and does not clog up the works. There was a smooth connection between the mouldboard and the share. There were different shapes and angles, so that the soil could be turned in different ways, landing in different patterns. Some of the earliest mouldboards already had the principles enunciated in 1784 by James Small, the

Scottish pioneer of scientific plough design, who wrote (unaware that he had been anticipated by 2200 years):

The back of the sock [share] and mouldboard shall make one continued fair surface without any interruption or sudden change. The twist, therefore, must begin from nothing at the point of the sock, and the sock and the mouldboard must be formed by the very same rule.

The Chinese knew, too, that the extra weight of an iron ploughshare and mouldboard were more than compensated by the dramatic reduction in friction of ploughing. Arthur Young wrote in 1797, two millennia later:

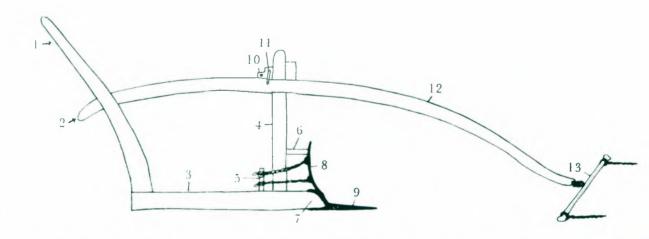

It appears that the weight of the plough is of little consequence, very contrary to common ideas.... The weight of the plough is the least part of the horse's labour; the great object is the resistance met with in the cohesion of the earth; lightness does nothing to overcome this; it is effected by just proportions only.

A good mouldboard design turns the clods right over, smoothly and with minimum friction, so that with a good plough, ploughing becomes like running a knife through butter, and just as a heavier knife will go through butter better, so a heavier plough will make a finer and deeper furrow with less trouble, if it has the proper design.

In Europe, mouldboards were completely unknown until late medieval times, and even then, they were extremely crude in their design. They were just flat bits of wood stuck on to the plough to provide an angled surface against which the upturned soil could collide and be deflected. The curved mouldboard, adopted from the outset in China, did not appear in Europe until the eighteenth century, and the lack of it probably caused more hardship to farmers than any other single factor. They had to stop repeatedly and scrape caught-up mud and weeds off their ploughs because there was no smooth connecting surface between the sharp, pointed share which cut the earth and the crude angled board which sent the clods to one side. The increased friction meant that huge multiple teams of oxen were required, whereas Chinese ploughmen could make do with a single ox, and rarely more than two.

Europeans had to pool their resources and waste valuable time and money in getting hold of six to eight oxen to plough the simplest field. This also meant leaving aside much more land for grazing, so that there was less for crops to produce food for human beings. It is no exaggeration to say that China was in the position of America and Western Europe today, and Europe was in the position of, say, Morocco. There was simply no comparison between the primitive and hopeless agriculture of

BELOW (FIG. 1) A drawing of the iron plough as described in Lu Kuei-Meng's book *The Classic of the Plongh* of 880. The relevant parts are: (9) the ploughshare which cuts the soil; (8) the mouldboard above, which turned the soil over neatly as the plough moved forward; (6) the mouldboard brace; (7) the wooden nose of the sole, or slade, onto which the iron ploughshare was snugly fitted; (12) the beam; and (13) the beginning of the 'whippletree', which was attached to each side of the beast or beasts pulling the plough.

Europe before the eighteenth century and the excellent and advanced agriculture of China after the fourth century BC.

Chinese ploughs, with mouldboards, were brought to Holland in the seventeenth century by Dutch sailors. And because the Dutch were hired by the English to drain the East Anglian fens and Somerset moors at that time, they brought with them their Chinese ploughs, which came to be called 'Rotherham ploughs'. Thus, the Dutch and the English were the first to enjoy efficient ploughs in Europe. Another name for the Chinese design was the 'bastard Dutch plough'. It was extremely successful on wet, boggy land, and it was soon realized that it would be just as successful on ordinary land.

From England it spread to Scotland, and from Holland it spread to America and France. By the 1770s it was the cheapest and best plough available. Western designers adapted and improved it considerably over the succeeding decades. James Small's plough of 1784 was a step forward, and the various nineteenth-century ploughs of J. Allen Ransome were further improvements. Steel frames were adopted, and the modern plough was born in the nineteenth century as a result of these improved Chinese ploughs. There was no single more important element in the European agricultural revolution. When we reflect that only two hundred years have elapsed since Europe suddenly began to catch up with and then surpassed Chinese agriculture, we can see what a thin temporal veneer overlies our assumed Western superiority in the production of food.

### EFFICIENT HORSE HARNESSES

FOURTH AND THIRD CENTURIES BO

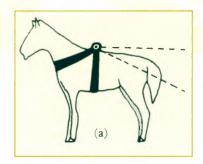

### THE TRACE HARNESS

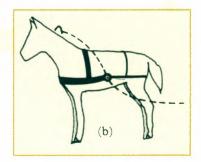

China was the only ancient civilization to develop efficient horse harnesses. There were none in ancient Europe. Thus through most of man's history he has been severely handicapped by the lack of an efficient means of harnessing horsepower for transport. This had an enormous effect on the course of history.

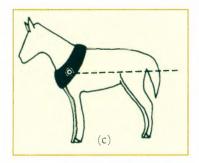

From earliest times until the eighth century AD in the West (and, as we shall see, much earlier in China), the only means of harnessing horses was by the 'throat-and-girth harness'. It was an absurd method since the strap across the throat meant that the horse was choked as soon as he exerted himself. Yet for thousands of years, nobody could think of anything better. As long as man was restricted to the use of this pathetic harness, horsepower was all but useless for transport by cart. Even individual riders could halfstrangle their mounts at a gallop. The confusion and slaughter of cavalry battles must have been much increased by inadequate harnessing. Long-distance rides would have been seriously impeded, no matter how good the horse and rider, by the fact that the poor horse was being not merely tired but also choked half to death. If ever the feebleness of human ingenuity has been displayed, it is by the fact that mankind was prepared to put up with the throat-andgirth harness for millennia.

Those who read about ancient Rome are often struck by the importance attached to the shipping of grain from Egypt. Without Egyptian grain, Rome

BELOW (FIG. 2) The three main forms of horse harness. (a) The throat-and-girth harness of Western antiquity, which severely choked the horse. (b) The trace harness, with its breast strap, which was in use in China by the fourth century BC. The horse can exert itself with this harness, since the pressure is on the chest bone (sternum) rather than the throat. The load is therefore borne by the horse's skeletal system rather than its windpipe. (c) The collar harness. From the third century BC the Chinese used this greater refinement. Again, the load is borne by the skeletal system by means of the pull on the chest bone (sternum). The collar is padded to avoid chafing the horse's skin.

must starve. But why? What was wrong with grain grown in Italy, one asks? Why was Rome dependent on ships from Egypt in order to be able to eat? The answer is simply that there was no horse harness capable of making it possible for Italian grain to be transported to Rome. We often overlook such technological factors when we seek to interpret events in the ancient world.

In about the fourth century BC the Chinese made a great breakthrough. A lacquered box of the period bears a painting which shows a yoke across the horse's chest, from which traces connect it to the chariot shafts. Although this cannot be considered a truly satisfactory harness, it shows that the throat-and-girth harness was abandoned in favour of a band across the breast of the horse. Soon, the hard yoke across the breast was also abandoned and replaced by the obviously more satisfactory breast strap, commonly called the 'trace harness'. There is no longer a strap across the horse's throat; the weight of the load is borne by the horse's chest and collar bones.

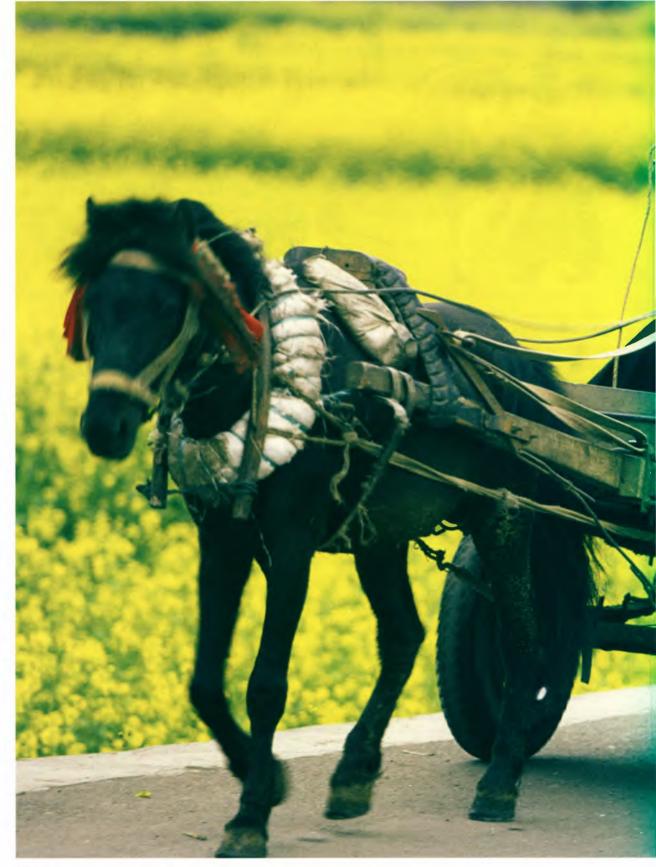

Experiments have been carried out to establish the relative efficiency of the different types of harness. Two horses harnessed in the throat-and-girth fashion can pull a load of half a ton. But a single horse in a collar harness (described below) can easily pull a ton-and-a-half. With a trace harness, the efficiency is only slightly less. As Needham says: 'The throat-and-girth harness would not have been able, therefore, to draw modern vehicles, even when empty.' The vehicles of the Greeks and Romans had to be so light, generally carrying no more than two people if they

ABOVE (6) A Han Dynasty relief of about the first century BC, showing the use of the trace harness, with its breast strap, to pull a typical carriage of that date. A precursor of the umbrella protects the passengers from sun and rain.

were for passengers, that effective transport by horse was impossible.

Needham suggests two factors which may have led the Chinese to invent the trace harness. There was the motivation of the Chinese, Mongols and Huns, living on the edge of the Gobi Desert where they were always getting stuck in the sand, from which horses using the throat-and-girth harness could not extricate them. Secondly, there was the use of human hauliers. Man's own experience of hauling, for example, canal boats upstream, meant that he was quickly aware of the inadequacy of a rope round the neck. Common sense dictated that the chest and collar bones should bear the weight. Therefore, the breast strap for the horse may well have been inspired by the breast strap used by humans.

The trace harness seems to have arrived in Europe by way of Central Asia. The Avars invaded Hungary from the East in 568 AD, and it is thought that they brought the trace harness with them. The same tribe brought the stirrup to Europe (see page 101). The harness spread to the Magyars, Bohemians, Poles and Russians. Evidence for trace harnesses has been found by archeologists in graves of the seventh to the tenth centuries. By the eighth century, the trace harness had made its way across Europe and it appears for the first time in a Western depiction on an Irish monument.

ABOVE (7) The collar harness in use in modern China.

The Vikings also acquired it. Various illustrations of it occur, notably in the Bayeux Tapestry of 1130, where it is shown in a ploughing scene.

### THE COLLAR HARNESS

The most efficient harness is the collar harness. It may be seen in the diagram in Figure 2. In the beginning, this harness effectively overcame a deficiency in the horse's anatomy and supplied a horse with a feature of the ox. An ox has a perfectly horizontal spine, with a hump more or less above the shoulders. A yoke can be fitted there with great ease, enabling considerable weights to be pulled. But a horse's neck is on an upward slope and has no hump. The earliest Chinese collar harness provided the horse with an artificial 'hump', to which a yoke was then attached. In other words, the horse was transformed into an ox-substitute by the collar and the hump it created at the top of the horse's neck. The collar was padded to avoid rubbing and causing sores on the horse's back.

The earliest evidence for the collar harness in China may be seen in a rubbing from an ancient brick, showing the collar harness on three horses pulling a chariot. It dates from some time between the fourth and first centuries BC. Therefore, we must consider the collar harness as having been invented in China by the first century BC at the latest. This is a full thousand years before its appearance in Europe a century after the trace harness.

After some time, it was found by the Chinese that the collar could be used in another and simpler way: traces could be attached from the sides of the collar directly to the vehicle. It is this form of the collar harness which is used today all round the world.

In connection with the collar harness of the modern form, the Chinese invented the 'whippletree', which is an attachment to a vehicle. If two horses pull a modern cart, the collars and traces lead to the whippletree. The earliest evidence of the whippletree in China goes back to the third century AD, in use with oxen.

One other factor in the invention of the collar harness might have been that similar collars had for some time been used to place baggage onto Bactrian camels. China had a Camel Corps and considerable familiarity with large numbers of the animals by the second century BC at the latest. The camel pack-saddle at that time was a felt-padded, horseshoe-shaped wooden ring, and, with some modifications, could have been used on a horse.

### THE ROTARY WINNOWING FAN

SECOND CENTURY BC

The Chinese were about two thousand years ahead of the West in their approach towards the winnowing of grain, the means used to separate out husks and stalks from the grain after harvest and threshing. The easiest method goes back even before the cultivation of crops: the grain is thrown up into the air, preferably in a strong wind, so that the chaff is blown away while the grain falls down to the ground. Later, winnowing baskets were used, which required dextrous handling. With the right kind of rhythmic wrist movement, one can separate the heavy grain from the chaff, which is gradually tipped over the edge of the basket, leaving the grain behind. Later still, the winnowing sieve was introduced.

But the Chinese were not satisfied with waiting for a strong wind for the tossing method, or with the slow and laborious basket and sieve methods. By the second century BC they had made a brilliant invention: the rotary winnowing fan. Models of them have been found in ancient tombs, made of pottery and with miniature working parts.

Grain was put into a hopper and was subjected to continuous streams of air which came from a crankoperated fan. The fan had a large air inlet behind it,

and was set at the end of a broad sloping tunnel leading towards the grain. The air from the fan blew the chaff away and out through a vent. The grain then fell down into a chaff-free pile beneath. One type of rotary winnowing fan was portable. This was an important development because the original machine was expensive, but could now be rented out, so enabling owners to recoup their costs. Another type was operated, not by a small crank handle suitable for one person, but by a treadle connected to a crank which left the operator's hands free to carry out other tasks at the same time.

The primary use of rotary winnowing fans was generally in the south of China, in connection with rice. Although apparently invented and first used in the north with wheat and millet, after several centuries the use shifted southwards and the device, for various economic reasons, was largely forgotten in the north. Many farmers reverted to the traditional tossing and hand-sifting of grain because they could not afford the fans.

A poem by the poet Mei Yao-Ch'en, or Mei Sheng-Yu, survives from the eleventh century, celebrating the rotary winnowing fan:

There on the threshing floor stands
the wind-maker,

Not like the feeble round fans of
the dog-days,

But wood-walled and fan-cranked,
a cunning contrivance,

He blows in his tempest all the
coarse chaff away,

Easy the work for those manning
the handles –

No call to wait for the weather, the breezes

To free the fine grain from its husks,
that our fathers

Needed for tossing their baskets on high.

The rotary winnowing fan was exported to Europe, brought there by Dutch sailors between 1700 and 1720. Apparently they had obtained them from the Dutch settlement of Batavia in Java, Dutch East Indies. The Swedes imported some from south China at about the same time and the Jesuits had taken several to France from China by 1720.

LEFT (8) A traditional rotary winnowing fan in use in modern China, in the southern province of Yunnan.

ABOVE (9) A glazed pottery model from the Han Dynasty (207 BC–220 AD), showing a grain pounder and a rotary grain mill. The figure on the right is turning the crank handle of a rotary winnowing fan, which was invented in the second century BC in China, but did not reach Europe until two thousand years later. Grain was poured into the open receptacle at the top for winnowing inside the machine. (The Scattle Art Museum, Eugene Fuller Memorial Collection.)

Until the beginning of the eightcenth century, no rotary winnowing fans existed in the West. Until then, tossing into the air with a shovel and sifting in winnowing-baskets were the primary techniques, though roughly fanning with canvases, blankets, and so on was occasionally practised from at least the early sixteenth century. But this rudimentary fanning was very rare and only adopted by the most professional farmers. It is estimated that the most advanced winnowing technique in common use in Europe before the eighteenth century was the winnowing basket. It could yield about 99 pounds of winnowed grain per hour, if done by an expert. But in the eighteenth century the Swedes studied a Chinese rotary winnowing fan which they had transported to Gothenburg, and discovered it could process an astonishing seventeen barrels of grain per day. European engineers were not slow to improve on the Chinese design, adapt it to European grain sizes, and even (something which the Chinese never did) combine it with threshing by machine as well.

Once more, we see the Chinese giving the West one of the most essential tools for the Western agricultural revolution. We might note, by way of a footnote, that the actual traditional Chinese rotary winnowing fan, though developed and improved immensely in the West, still survives in its basic form in the Third World countries of today, where it is found to be cheaper and more practical than modern Western versions.

# THE MULTI-TUBE ('MODERN') SEED DRILL

SECOND CENTURY BC

It may come as a surprise to those who are unfamiliar with the history of Western agriculture to learn that the West had no seed drills until the sixteenth century AD. Until the seed drill was adopted, broadcasting of seed by hand was practised. This was appallingly wasteful, and it was common for as much as half the crop to have

to be saved for sowing the next year. Of those seeds which then germinated, many fell into hollows in the ground, with the resulting plants all being clumped together, competing for moisture, light and nutrients. Also, proper weeding was out of the question because it was impossible to get at the weeds.

Although it never made its way to Europe, the Sumerians of the Middle East had a primitive single-tube seed drill 3500 years ago. But it was the multitube seed drill invented by the Chinese in the second century BC (and adopted also in India) which made possible the efficient sowing of crop seed for the first time in history. The drill is pulled along behind the horse, ox, or mule and dribbles the seed at a controlled rate into straight rows.

Small iron seed drill shares have been excavated in China, dating from about the second century BC. A government official named Chao Kuo introduced the seed drill to the metropolitan area of the capital in 85 BC. We read of this in a surviving fragment of a book called On Government:

Three ploughshares were all drawn by one ox, with one man leading it, dropping the seed and holding the drill simultaneously. Thus, 100 mu could be sown in a single day....

The later agriculturalist, Wang Chen, gives more details:

The *luo* ... or sowing shares are the shares ... that trace the drill, like a triangular ploughshare but smaller, with a high ridge down the centre, 4 inches long and 3 inches wide. They are inserted into the two holes at the back of the seed-drill's feet and bound tightly to the crosspiece. The share bites 3 inches or so deep into the soil, and the seed dribbles down through the foot of the drill, so it is sown very deep in the soil and the yield is improved. Soil tilled with a seed-drill looks as if it had been gone over with a very small plough.

The Chinese system was at least ten times as efficient as the European one, and could be up to thirty times as efficient, in terms of harvest yield. And this was the case for seventeen or eighteen hundred years. Through all those centuries, China was so far in advance of the West in terms of agricultural productivity that the contrast, if the two halves of the world had only been able to see it, was rather like the contrast today

between what is called the 'developed world' and what is called the 'developing world'.

The inspiration for the first Western seed drills came from China. But because seed drills were mostly used in north China, far from the ports of south China frequented by Europeans, actual specimens were not transported to Europe for examination. What came over was a rather imprecise account and description of the device. Word of mouth combined with inadequate descriptions and pictures in Chinese books meant that the frustrated Europeans receiving this news could not quite fully understand it. They were therefore forced to reinvent the seed drill. As a result, European seed drills were based on principles quite different from the Chinese principles. This was a case of 'stimulus diffusion' - the transmission of an idea without the accompanying details of construction. So the Europeans finally got their seed drills, but at the cost of working it all out from scratch.

The earliest European seed drill was patented by the Venetian Senate in 1566; its inventor was Camillo Torello. The earliest for which we have detailed descriptions was that of Tadeo Cavalina of Bologna, in 1602; it was very primitive. The first really sound seed drill in Europe was that developed by Jethro Tull. This drill was first produced soon after 1700, and descriptions of it published in 1731. However, seed drills of this and successive types were both expensive and unreliable, as well as fragile. Sturdy, sound seed drills became available in quantity in Europe only in the mid-nineteenth century. Until that time, Jethro Tull's vision of an agricultural revolution was somewhat delayed in its full form.

There had been a very fine seed drill in the eighteenth century in Europe, invented by James Sharp, but it was only for single-row sowing and was too small, so that its perfect functioning did not attract sufficient interest. Basically, it was a lack of engineering skill which made European seed drills essentially ineffective and uneconomical until the middle of the nineteenth century. Thus, two centuries of knowledge of seed drills were wasted, due to the failure to exploit the principles properly.

OPPOSITE (10) The multi-tube seed drill was in use in China by the second century BC. Europeans had no seed drills at all until the sixteenth century. Here we see spring wheat being sown in north China, in an engraving published in 1742 in Compendium of Works and Days, compiled by O-Erh-T'ai.

# TRONOMY AND CARTOGR

### RECOGNITION OF SUNSPOTS AS SOLAR PHENOMENA

FOURTH CENTURY BO

In the West, the heavens were supposed to be so perfect that no such thing as a sunspot could be thought possible. Most of the sunspots seen in the West before the seventeenth century were explained away as transits of the Sun by the planets Mercury and Venus. The theory of 'perfection of the Heavens' forbade the admission of any imperfections on the surface of the Sun. Consequently, it was assumed that these 'blemishes' were planets or small invisible satellites.

The Chinese suffered from no such preconceived insistence on 'perfection'. Since sunspots are sometimes large enough to be seen by the naked eye, the Chinese naturally saw them. The earliest surviving record we have of their observations would seem to be some remarks by one of the three known early astronomers in China. He was Kan Te, who lived in the fourth century BC. He and two contemporaries, Shih Shen and Wu Hsien, drew up the first great star catalogues. Their work was fully comparable to that of the Greek Hipparchos, though two centuries earlier.

Kan Te appeared to be referring to sunspots when he spoke of solar eclipses which began at the centre of the Sun and spread outwards. Although he was incorrect, this has the merit of being eminently reasonable, and showed that Kan Te recognized that the sunspots were solar phenomena, and characteristics of the Sun which partly darkened its surface.

The next indication of a sunspot observation dates from 165 BC. We are told in a much later encyclopedia, *The Ocean of Jade*, that in that year, the Chinese character Wang appeared in the Sun. This was therefore a sunspot which appeared not round, but shaped like a cross with a bar drawn across the top and the bottom. The astronomer D.J. Schove accepts this as the world's earliest precisely dated sunspot. The recording of sunspot observations in the voluminous official imperial histories of China commenced on 10 May 28 BC. But systematic Chinese observations of sunspots probably began at the latest by the fourth century BC, and only the loss of much literature of that time denies us more specific information.

There are reasons for believing that the early natural philosopher Tsou Yen, the loss of whose writings is so much lamented, included sunspot observation in his school's curriculum. If the works of Tsou Yen could ever be recovered from one of the Han tombs, as have works on medicine and other subjects, a huge gap would be filled in our knowledge of early science.

Most people today believe that sunspots were first observed in the West by Galileo, who is also supposed to have been the first person to 'invent' or at least use the telescope. Neither belief is true. Galileo most certainly did not invent the telescope, though he gave it prominence, and courageously advocated its use to study the heavens. As for the observation of sunspots, the earliest clear reference to them so far found in Western literature is in Einhard's *Life of Charlemagne*, of about

OPPOSITE (11) The Chinese had recognized that sunspots were features on the surface of the Sun by the fourth century BC. Until the sixteenth century Western observers thought they were objects in intervening space. This illustration of sunspots is from a Chinese manuscript by the Ming Emperor Chu Kao-Chih entitled *Essay on Astronomical and Meteorological Presages*. Written in the year 1425, this work was never printed, but the manuscript survives. This painting was done by the Emperor himself. (Cambridge University Library.)

807 AD, or eight centuries before Galileo's first observation of sunspots in 1610.

Later sunspot observations in the West were made by the Arab Abu al-Fadl Ja'far ibn al-Muqtafī in 840 AD, by Ibn Rushd about 1196, and by Italian observers around 1457. Galileo's priority in the seventeenth century was disputed by the Jesuit Christopher Scheiner in Holland, by Fabricius in Germany, and by Thomas Hariot in England, all of whom seem to have seen the sunspots before Galileo did.

Needham has counted the numbers of sunspot observations in the official histories between 28 BC and 1638 AD, and has found 112 instances. There are also hundreds of notices of sunspots in other Chinese books during the centuries, but no one has ever had the time or stamina to collect them all together in a body. These Chinese records are the oldest and longest continuous series of such observations in the world. Many of the specific descriptions are full of interest. Extensive, though incomplete, lists of them exist in various old Chinese encyclopedias, and some of these have been published in English. The extreme importance of these lists may be seen from the fact that modern astronomers have tried to analyze them to determine cycles in the occurrence of sunspots. It is well known that a period of about eleven years appears during which sunspots seem to increase, decrease, and then begin to increase again.

Since these cycles have an effect upon the Earth's ionosphere and weather ('magnetic storms' in the atmosphere are related to sunspot periods), the more we know about these the better. By studying the most complete available list of the Chinese material, the Japanese astronomer Shigeru Kanda believed he had detected a 975-year cycle in sunspots. If the Sun has a period of 975 years, that may have important implications for weather cycles on our planet, and directly affect the futures of us all.

### QUANTITATIVE CARTOGRAPHY

SECOND CENTURY AD

The science of map-making took a great step forward when Chang Heng invented quantitative cartography in the second century AD. Chang was the inventor of the first seismograph (page 177) and one of China's leading scientific figures. He first applied the grid system to maps so that positions, distances and itineraries could be calculated and studied in a more

scientific way. The Chinese tradition of applying grids to maps eventually developed so far that by the Middle Ages schematic grid-maps were actually appearing with only the grid and names, omitting the map itself. (See Plate 13 (page 34).) Geographical positions on such extreme mathematical abstractions were determined by counting the X and Y coordinates of the grid. This was quantitative cartography of a kind more suitable to a computer, since it entirely dispensed with images.

Chang Heng's own works on cartography are lost. He wrote a book entitled *Discourse on New Calculations* which apparently laid the groundwork for the mathematical use of the grid with maps; another of his books seems to have borne the title *Bird's-Eye Map*; and we know that he presented a map to the emperor in 116 AD. The most important piece of evidence we have regarding his role, however, is the statement in the official history of the Han Dynasty that he 'cast a network of co-ordinates about heaven and earth, and reckoned on the basis of it'.

In the third century, Chang had a successor in the scientific study of cartography. He was P'ei Hsiu, who in 267 was appointed Minister of Works by the first emperor of the Chin Dynasty. The official history quotes the following from his preface to a great map in eighteen sheets which he presented to the emperor:

The origin of maps and geographical treatises goes far back into former ages. Under the three dynasties [Hsia, Shang and Chou] there were special officials for this. Then, when the Han people sacked Hsien-yang, Hsiao Ho collected all the maps and documents of the Ch'in. Now it is no longer possible to find the old maps in the secret archives, and even those which Hsiao Ho found are missing; we only have maps, both general and local, from the later Han time. None of these employs a graduated scale and none of them is arranged on a rectangular grid. Moreover, none of them gives anything like a complete representation of the celebrated mountains and the great rivers; their arrangement is very rough and imperfect, and one cannot rely on them. Indeed some of them contain absurdities. irrelevancies, and exaggerations, which are not in accord with reality, and which should be banished by good sense....

In making a map there are six principles observable:

- 1) The graduated divisions, which are the means of determining the scale to which the map is to be drawn.
- 2) The rectangular grid (of parallel lines in two dimensions), which is the way of depicting the correct relations between the various parts of the map.
- 3) Pacing out the sides of right-angled triangles, which is the way of fixing the lengths of derived distances (i.e., the third side of the triangle which cannot be walked over).
- 4) Measuring the high and the low.
- 5) Measuring right angles and acute angles.
- 6) Measuring curves and straight lines. These last three principles are used according to the nature of the terrain, and are the means by which one reduces what are really plains and hills to distances on a plane surface.

If one draws a map without having graduated divisions, there is no means of distinguishing between what is near and what is far. If one has graduated divisions, but no rectangular grid or network of lines, then while one may attain accuracy in one corner of the map, one will certainly lose it elsewhere (i.e., in the middle, far from guiding marks). If one has a rectangular grid, but has not worked upon the principle of pacing out the sides of right-angled triangles, then when it is a case of places in difficult country, among mountains, lakes or seas (which cannot be traversed directly by the surveyor), one cannot ascertain how they are related to one another.... But if we examine a map which has been prepared by the combination of all these principles, we find that a true scale representation of the distances is fixed by the graduated divisions.... When the principle of the rectangular grid is properly applied, then the straight and the curved, the near and the far, can conceal nothing of their form from us.

P'ei Hsiu's actual map has not survived. Note that it was placed in the secret archives. This was not exceptional, for throughout history, and especially in China, the possession of superior maps was the key to political and military success, analogous to having advanced strategic weapons today. Shen Kua, in his

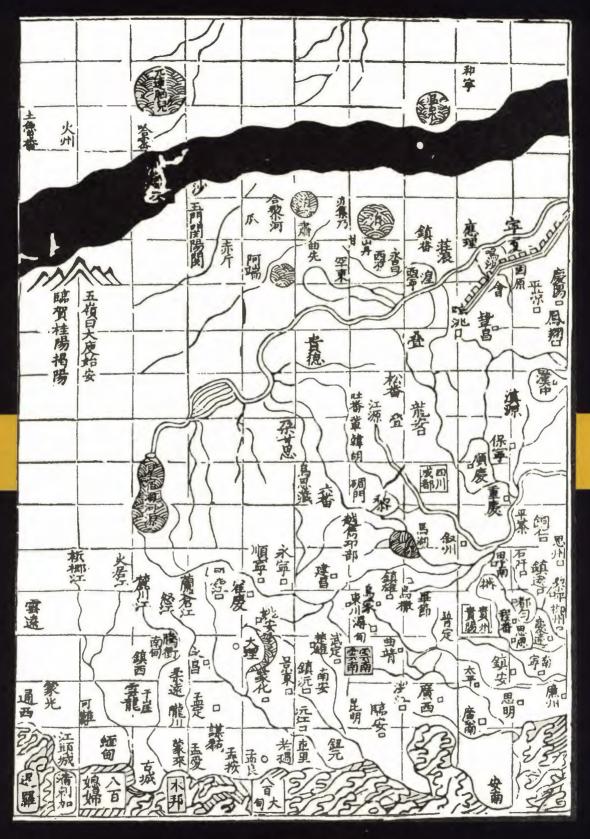

*Dream Pool Essays* of 1086, gives the following illuminating story:

In the Hsi-Ning reign-period [1068 to 1077 AD] ambassadors came from Korea bringing tribute. In every lisien city or provincial capital which they passed through they asked for local maps, and these were made and given to them. Mountains and rivers, roads, escarpments and defiles, nothing was omitted. When they arrived at T'iehchow they asked for maps, as usual, but Ch'en Shu-Kung, who later became Prime Minister but was at that time in charge of the military guard at Yangchow, played a trick on them. He said that he would like to see all the maps of the two Chekiang provinces with which they had been furnished, so that he could copy them for what was now wanted, but when he got hold of them, he burnt them all, and made a complete report on the affair to the emperor.

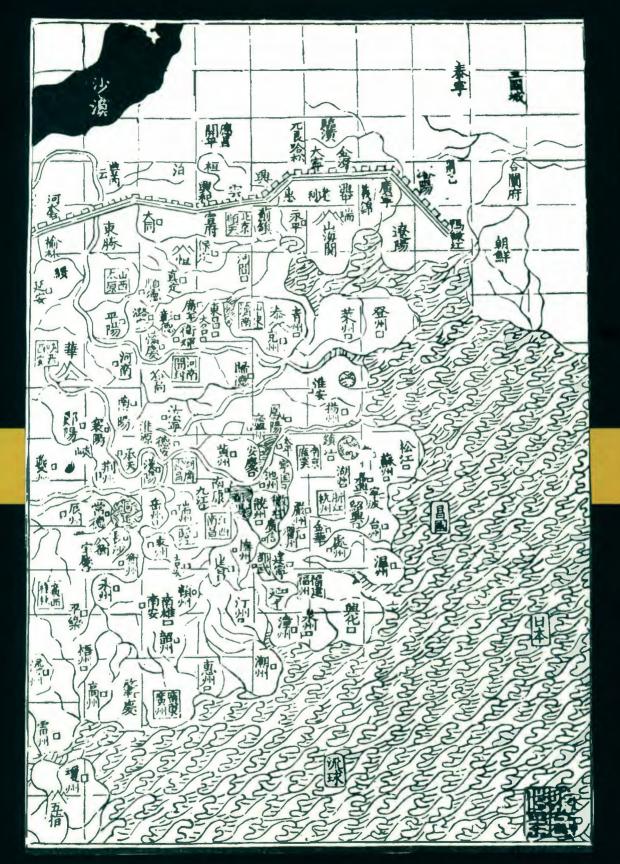

It is easy to understand how so many early maps did not survive; they were not copied, and were frequently destroyed. Their information was simply too dangerous to risk its falling into the wrong hands. However, two splendid maps of the eleventh century carved in stone survive. Both are preserved in the Pei Lin Museum at Sian, in China. One of them, 'Map of the Tracks of Yü the Great', has a rectangular grid laid over it. It is generally superior to the other map, and especially so with regard to the coastal details; also it includes the Shantung peninsula, which the other has omitted. But the other incorporates much more accurate information about the south-western rivers. The two maps therefore each display a regional bias.

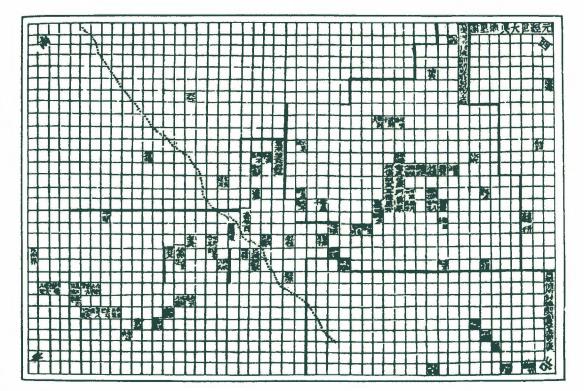

Another great map is that of Chu Ssu-Pen, prepared between 1311 and 1320. This map existed only in manuscript for two centuries but was finally printed in about 1555 in the *Enlarged Terrestrial Atlas* in an edition by Lo Hung-Hsien (1504-64). Lo says of the map:

Chu Ssu-Pen's map was prepared by the method of indicating the distance by a network of squares, and thus the actual geographic picture was faithful. Hence, even if one divided the map and put it together again, the individual parts in the east and west fitted faultlessly together.... His map was seven feet long and therefore inconvenient to unroll; I have therefore now arranged it in book form on the basis of its network of squares.

ABOVE & OPPOSITE (12) Part of Chu Ssii-Pen's great map of China which he prepared between 1311 and 1320, and which he called Earth-Lehicle Map. This section was printed in about 1555 in the Enlarged Terrestrial Atlas, the preface to which informs us: 'Chu Ssii-Pen's map was prepared by the method of indicating the distances by a network of squares, and thus the actual geographic picture was faithful.' The black band in the upper left represented the Gobi Desert. The Great Wall of China may be seen clearly along the top, and to the right are the Yellow Sea and the East China Sea.

ABOVE (13) The schematic grid has entirely usurped the pictorial aspect of this map of the north-western part of China, which has North in the bottom right-hand corner. Places are simply marked off where they lie on the grid, and other surface features are ignored. This is known as the 'Mongolian Style' of cartography, from the fact that it was practised in 1329 under the Mongol (Yuan) Dynasty of China. The map is from the book of that date. History of Institutions of the Yuan Dynasty.

Thus we see the grid used successfully to reduce the size of the map in a manner analogous to photographic reduction. (See Plate 12 (page 32–3).)

What was happening in Europe while all this was going on? After the time of Ptolemy (c. 120–170 AD), Western map-making degenerated under the influence of religion to a point scarcely credible. For instance, a well-known Western world map from a manuscript of 1150 is so pathetically inaccurate that it hardly even rates the description of 'map'. It was only during the Renaissance that respectable maps once more began to be found in Europe. Fourteenth-century sailing charts (called portolans) were of good quality, but reasonable maps of larger areas did not appear in Europe until the fifteenth century – thirteen hundred years after Chang Heng introduced scientific, quantified cartography in China.

### DISCOVERY OF THE SOLAR WIND

SIXTH CENTURY AD

Comet tails always point away from the Sun, blown that way by the 'solar wind'. The Chinese were history's most noted observers of comets. The computation of approximate orbits for about forty comets appearing before 1500 have been based almost entirely upon Chinese records of their sightings. Comet movements were described with such precision by the Chinese that many precise trajectories across the sky can be drawn on a star map, simply from reading an ancient Chinese text. This report of 1472 describes one comet's movements:

Suddenly it went to the north, touched the star 'Right Conductor' (in Boötes), and swept through the 'Enclosure' of stars in Virgo, Coma Berenices and Leo, touching nu Coma Berenices, 2629 Coma Berenices, E Leonis, and 2567 Leonis. Its tail now pointed directly toward the west. It swept transversely across a to k Comae Berenices.... On a chia-mao day its tail had greatly lengthened. It extended from east to west across the heavens. The comet then proceeded northwards, covering about 28°, touched iota, theta and chi Boötes, swept through the Great Bear, and passed near the three small stars at the north of Canes Venatici and chi Ursae Majoris....

It will be noticed with what attention the precise position and direction of the tail of each comet was studied. (The stars named here are obviously the modern equivalents, the Chinese names being omitted.)

From at least the seventh century AD, and probably the sixth, the Chinese observations of comet tails had been refined enough to establish the principle that comet tails always point away from the Sun. We find a clear statement of this principle in the official history of the T'ang Dynasty for 635 AD: 'In general, when a comet appears in the morning, its tail points towards the west, and when it appears in the evening, its tail points towards the east. This is a constant rule. If the comet is north or south of the Sun, its tail always points following the same direction as the light radiating from the Sun.'

The astronomers of that time already realized that comets shine by reflected light, like the Moon. It is now known that comet tails always point away from the Sun because they are so tenuous that the force of the 'solar wind' pushes them away into that position. In other words, radiation from the Sun has sufficient force to act upon them as a wind would do.

Did the Chinese in the sixth century AD merely discover this empirically, or go so far as to formulate the notion of the 'solar wind' itself? There is no unambiguous evidence, but on balance it is highly likely that the Chinese did not even need to formulate the theory of the 'solar wind'. It would have been so congenial to their underlying assumptions about the Universe that it would probably have been taken for granted as the explanation as soon as they had formulated (as in the text of 635 AD above) the principle that comet tails followed the same direction as the Sun's radiation. For Chinese literature is replete with countless references to the ch'i of the Sun's radiation. This concept of ch'i, which is essentially untranslatable, can in this context be thought of as the 'emanative or radiative force' coming from the Sun. To the ancient Chinese, it would have been obvious, believing as they did in this ch'i, that the Sun's ch'i was strong enough to blow the tails of comets away from the Sun, as in a high wind. And that the Chinese conceived of space as being full of strong forces, we can see in our account of manned flight with kites (page 191).

BELOW (14) Comets (or 'broom stars') are depicted here in relation to different star groupings in the sky. These are illustrations from a manuscript of an unpublished work entitled *Tine Canon of Understanding the Mysteries (T'ung-hsiian Ching*). By careful observation of the tails of comets over the millennia, the Chinese were able – no later than the sixth century AD – to postulate the existence of a solar wind which blew the tails away from the sun. The text on the right says: 'If a comet invades the Ti. Fang, or Hsin stars, there will be floods and war in the area of the Sung State. The people there will suffer great vicissitudes, and this will happen within three years.' In the middle: 'If a comet invades the Wei star or Chih star, there will be serious drought for one year, and a shortage of food production in the region of the Yan State, and this will happen very soon.' On the left: 'If a comet invades the Hsii and Wei stars, it indicates that there will be a poor harvest and trouble for the people, within one year. This sign never fails.' (Collection of Robert Temple.)

RIGHT (15) A Chinese star map drawn on a 'Mercator' projection, c.940, discovered by Sir Aurel Stein at Tunhtuang. Here we see three hour-angle segments of the sky. Among the stars and constellations shown are Orion, Canis Major, Canis Mmor, Lepus, Cancer and Hydra. They have different configurations in Chinese astronomy; Sirius, the Bow Star, is the target at which the bow and arrow at bottom left are pointing. Some stars are differently coloured from others, to indicate that they were discovered, or at least commented upon, by different astronomers. (British Library, London.)

### THE MERCATOR MAP-PROJECTION

TENTH CENTURY AD

The Mercator map-projection is the map of the world most commonly seen on the walls of classrooms, in which Greenland is enormous and the north and south polar regions appear larger than Europe and America.

The projection is a cylindrical projection; that is, if one inserted a transparent globe of the Earth in the centre of a hollow cylinder and then turned on a light-bulb inside the globe, the features of the Earth's surface thrown onto the cylinder would be those of the Mercator projection. The equator is a straight line running across the middle of the Mercator projection and only the features near the equator are anything like their proper shapes. The higher up and lower down on the globe, the more the features are distorted by being cast onto portions of the cylinder which are further away. The projection is virtually useless for land travel, but is very popular at sea because it has the peculiar feature that a navigational course drawn on it comes out as a straight line, whereas with other maps such courses are arcs.

The Mercator projection originated, in Europe, as the presumed invention of Gerardus Mercator, which is the Latin name of Gerhard Kremer (1512-94), a Flemish mathematician and geographer. He

published the first map on 'Mercator's projection', a navigation map, in 1568.

The cylindrical projection, however, was used by the Chinese centuries before Mercator. A manuscript star map dating from about 940 AD is preserved in the British Library (see Plate 15 (above)). This map presents the celestial globe (that is, the sky portrayed as a globe) as projected onto a surface by the cylindrical projection technique. The Chinese divided the sky into twenty-eight sections called *hsiu*, which were rather like the sections of an orange. They were 'lunar mansions' (stages of the moon's progress through the sky) with the pole at their centre. In this star map, the *hsiu* are represented as long rectangles centred on the equator and very distorted towards the poles.

A century-and-a-half later, Su Sung (see page 121-2) published further Mercator-style map-projections in his book *New Design for a Mechanized Armillary Sphere and Celestial Globe*, published in 1094. One of these had a straight line running across the middle as the equator and an arc above it, the ecliptic. The rectangular boxes of the lunar mansions are clearly seen, with the stars near the equator being more tightly packed together and those near the poles spread further apart. Su Sung published two star maps on the 'Mercator projection' and two on polar projections. These are the world's oldest published star maps of any kind.

# EQUATORIAL ASTRONOMICAL INSTRUMENTS

THIRTEENTH CENTURY AD

Modern astronomical observatories derive from a Chinese, not a European tradition, which makes an understanding of sky positions easier. They are oriented and mounted according to what is known as

the equatorial system of astronomy. This is traditionally Chinese, and it goes back to at least 2400 BC. It takes the equator as the horizontal circle around the side of the instrument, and the pole as the top point. This may seem simple and obvious, but it was not the system used by our own European ancestors. In our tradition, which is called 'ecliptic', the two horizontal circles which were of importance were not the equator but the horizon and the ecliptic (the circle described by the Sun's motion in the sky, which is the same plane as the Earth's orbit around the Sun). Whereas Europeans more or less ignored the equator, the Chinese largely ignored the horizon and the ecliptic. But when making astronomical observations, it came to be realized in seventeenth-century Europe that the Chinese system of equatorial astronomy was more convenient and showed greater promise. So it was adopted by Tycho Brahe (1576-1601) and his successors and is still the basis of modern astronomy today.

The Chinese system was really very simple. Everything was conceived of as radiating from the celestial pole, as if it were the point where the stem of an orange were attached. The sky was then divided up into twenty-eight sections rather like orange segments, known as *hsiu*, or lunar mansions. Each one of these *hsiu* contained certain star constellations which were known and given names. Since the pole star and the stars near it never set beneath the horizon at any time during the year (whereas most stars do), the Chinese gave greatest attention to them, and by noticing

is given by Needham, from whom this diagram is taken.

LEFT (FIG. 3) A diagram of Kuo Shou-Ching's equatorial CEL POLE torquetum. The observer could see the Pole Star by standing bottom left and looking up through the centre of the equatorial circle (j) (which is 6 feet in diameter), through the small circle (b) and along the arrow pointing at the Celestial Pole. The central sighting tube (i) is here shown pointing straight upwards. It could be rotated within the declination ring (f) for the observation of various stars whose positions could be read off in degrees on the metal rings. Thus, whatever star one cared to look at, an automatic reading of its position in the sky would be indicated by virtue of the fact that the Pole Star was centrally sighted. This is what is meant by the instruments being 'equatorially mounted'. The system was adopted from Chinese astronomy by Europeans in the seventeenth century, and is still used today. The azimuth circle (ni) and the altitude measurement circle (n) were, like the other circles, graduated with degrees incised into their rims. A full description of the instrument

where the stars at the top of a sky segment were, they could then precisely specify where the stars at the bottom of the same sky segment were, even though they might be invisible beneath the horizon.

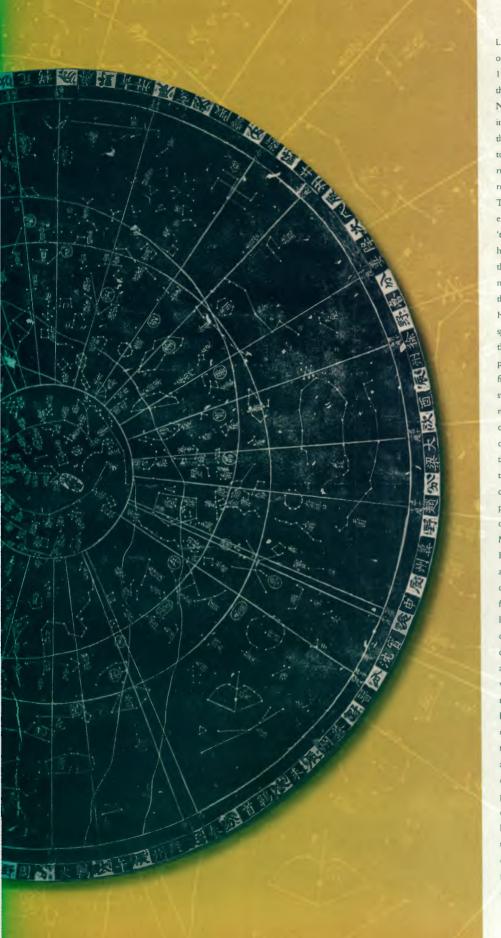

To do this sort of thing with precision required instruments. The Chinese had such superior expertise in metal casting, having after all invented cast iron (see page 44), that they made large and impressive instruments of bronze and iron. These would take the form of huge metal rings precisely graduated with the degrees of the circle. Different rings representing different sky-circles would then be joined together at the two points where they crossed one another, forming what looked like the skeletons of spheres. These we call armillary spheres, from the Latin word armilla, meaning 'bracelet'. One ring would obviously represent the equator. Another would represent what is called the meridian, which is a great sky-circle that passes directly over one's head and also through the pole.

These instruments also had sighting-tubes, through which one could peer at particular stars. The sighting-tube was moved along the equator ring until a star was found. Then one counted the number of degrees marked on that ring back to the meridian ring, which stood up from it vertically. As soon as the degrees had been counted, the exact position of the star along the equator would become clear and one could tell what sky segment it was in. By such means as these, star maps were drawn with great precision, and positions of stars were recorded. The sky became not a maze of points of light, but a sensibly ordered arrangement of constellations. And to make sense of the night sky is, after all, what astronomy is.

Armillary rings still exist today in the form of the mountings which allow the great modern telescopes to be oriented to particular points in the sky. But instead of mere sighting-tubes today, we have the additional aids of lenses or mirrors to peer at our stars, so we can not only find the star positions, but stare closely at the stars, magnified greatly, and observe things about them that are not apparent to the unaided eye. In the past, finding the positions of stars was an end in itself; today it forms the basic framework enabling us to carry out further studies.

The Chinese astronomer Keng Shou-Ch'ang introduced the first permanently mounted equatorial armillary ring in 52 BC, and the astronomers Fu An and Chia Kuei in 84 AD added a second ring to show the ecliptic. Chang Heng (who also invented the first seismograph – see page 177) added a ring for the

LEFT (16) The Suchow Planisphere, or map of the night sky, dating from 1193 AD, drawn for the heir to the throne, who would rule as Emperor Ning Tsung (1195-1224), by his imperial tutor Huang Shang. In 1247, this planisphere was carved in stone to preserve it forever; this image is a rubbing of that stone (only ten such rubbings were ever authorized). The inner circle which matches the exterior circle is the equator, called 'the red road which encircles the heart of heaven.... With regard to the two poles it occupies exactly the mid-distance between the south and the north and constitutes the heart of Heaven, wherein dwells the central spirit'. The eccentric inner circle is the ecliptic ('the yellow road'). The parallel pair of wiggly lines drawn from the bottom right upwards, sweeping across to the top left, represent the Milky Way ('the river of heaven'). The lengthy text of the Suchow Planisphere states that there are 1565 named stars in the night sky (although only 1440 of them are represented on this planisphere). Between 4 and 5 o'clock is the constellation of Canis Major, known to the Chinese as the Bow Star and depicted by a bow and arrow. (Chinese depictions of constellations are wholly different from those in the West). The many lines radiating outwards from the centre of this planisphere, which divide the sky into unequal sections, are indications of the boundaries of what the Chinese called the 'lunar mansions'. These form the basis of a highly complex theoretical division of the sky which is fundamental to traditional Chinese astronomy. I also have in my collection a very old and large original painted planisphere which omits the ecliptic and is wholly equatorial, but it is somewhat damaged and there are portions which have been obliterated, so it was not suitable for reproduction here. (Collection of Robert Temple.)

LEFT (17) A jade circumpolar constellation template. An ancient Chinese astronomer would have held this up at approximately arm's length, with the Pole Star in the centre. The jagged outer edges of the circle would then have perfectly matched the pattern of stars surrounding the Pole Star: that is, a star would twinkle in each tiny notch in the jade. These templates varied with time because of the shifting positions of the Stars.

Although the date of this one has not been determined, similar ones have been dated to 1000 BC and 600 BC.

Unique to China, they were used to find orientations in the sky in the study of the constellations, and were among the earliest and most primitive equatorial astronomical instruments. (Victoria and Albert Museum, London.)

meridian in 125 AD, as well as one for the horizon. By that date, the true armillary sphere could be said to exist in its full form. But Chang Heng was not yet satisfied. He made non-observational armillary spheres rotate by water power, about 132 AD. He used a water wheel powered by a constant pressure-head of water in a clepsydra (water-clock mechanism) to rotate his sphere slowly. Here is a description in an official history:

Though many have discoursed upon the theory of the heavens, few have been as well acquainted with the principles of the yin and the yang as Chang Heng ... Chang Heng made his bronze armillary sphere and set it up in a closed chamber, where it rotated by the force of flowing water. Then, the order having been given for the doors to be shut, the observer in charge of it would call out to the watcher on the observatory platform, saying the sphere showed that such and such a star was just rising, or another star just culminating, or yet another star just setting. Everything was found to correspond with the phenomena like the two halves of a tally.

Another passage in the official history tells us:

In the time of the emperor Shun Ti (126–144 AD) Chang Heng constructed a computational armillary, which included the inner and outer circles, the south and north celestial poles, the ecliptic and the equator, the twenty-four fortnightly periods, the stars within [i.e., north

of] and beyond [i.e., south of] the twenty-eight hsiu, and the paths of the sun, moon and five planets. The instrument was rotated by the water of a clepsydra [lit. dripping water] and was placed inside a closed chamber above a hall. The transits, risings and settings of the heavenly bodies shown on the instrument in the chamber corresponded with those in the actual heavens, following the motion of the trip-lug and the turning of the auspicious wheel.

This water-powered rotating instrument was a tremendous tool for demonstrating (and computing) the movements of the heavenly bodies. It must have given astronomers of the time a sense of intellectual power. Chang Heng is also said to have constructed one which was actually for observation of the stars – obviously not inside a chamber – which was also water-powered. However, full descriptions of it do not survive.

An astronomical instrument which is one step up on the armillary sphere is the torquetum, invented by the Arabs. With this instrument, all the various rings and so on are not nested together in a single sphere, but are mounted at various different parts of a set of struts, in a way more convenient and advanced than is allowed by the constraints of the single sphere. A non-equatorial form of the torquetum was transmitted by the Arabs to the Chinese. In Plate 18 (opposite) and Figure 3 (page 37) we see the great metal equatorial torquetum of the astronomer Kuo Shou-Ching of 1270 which was called the 'Simplified Instrument'. This was because it was made purely equatorial, and had all the Arab ecliptic components left out. We are fortunate that this

great instrument survives, for the Jesuits melted down many such metal instruments in China as scrap. The base plate of this instrument measures 18 by 12 feet, the revolving meridian ring in the centre is 6 feet across, and its sighting-tube is thus the height of a man.

Kuo had taken the torquetum of the Arabs and adapted it to the equatorial system of the Chinese. Needham says of this huge machine that 'it constitutes the precursor of all equatorial mountings of telescopes', and of Kuo's accomplishment:

...though Arabic influence may have been responsible for suggesting its construction, Kuo adapted it to the specific character of Chinese astronomy, namely equatorial coordinates. And in so doing, he fully anticipated the equatorial mounting so widely used for modern telescopes.

Needham believes that some knowledge of this reached Tycho Brahe in Denmark three centuries later, and led to Brahe's taking up equatorial astronomy for his instruments. As for the transmission of the idea from China, Needham believes it came from the Arabs to Gemma Frisius in 1534, and from him to Tycho Brahe. And through him and his successor, Johannes Kepler, modern European astronomy came to be equatorial in the Chinese manner. Since Kuo Shou-Ching in thirteenth-century China, M.C. Johnson emphasizes that: 'Actually our present-day equatorial mounting has made no further essential advance.' Here indeed is a Chinese contribution to an aspect of modern Western science which is barely appreciated.

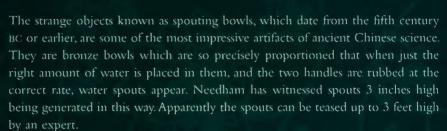

BELOW (18) Kuo Shou-Ching's famous 'Simplified Instrument' of 1270, at the Purple Mountain Observatory in Nanking, seen from the east. It was originally constructed for use at Linfen in Shansi, but was moved to Nanking during the Ming Dynasty, when it was no longer appreciated that the difference of 3½° in latitude rendered it useless. At its original latitude, the Pole Star would have appeared at the precise point required for the use of this equatorially mounted instrument. Cast in bronze and weighing several tons, the declination ring (centre) is 6 feet across. See Figure 3, page 37.

# Part 3 ENGINEERING

### SPOUTING BOWLS AND STANDING WAVES

FIFTH CENTURY BO

The vibrations set up in the bronze by rhythmic rubbing of the bowl with the hands is supposed to cause the precise frequencies necessary to generate what are called 'standing waves', whose only movement is up and down. The spouts of water rise from these waves.

A bronze spouting bowl is, in effect, the equivalent of a vibrating string on a musical instrument; its vibrations, like those of the string, have certain points, called nodes, where the vibration drops to zero. If a coin is placed on the correct node of a vibrating piano wire, the note will continue to sound because that precise point on the wire is in any case motionless. At the nodes, therefore, within the substance of the bronze bowl, standing waves are formed when the bowl is set vibrating.

The four nodes of the bowl were somehow determined in advance, so the bowl could be cast with decorations pointing at them – in this case, lines emanating from the mouths of fish, an amusing pictorial guide to the nodes, which determine where the real spouts will occur, generated as the spouts are in the areas between the nodal points.

These spouting bowls, which are triumphs of precision casting, are evidence of total control of the dimensions and proportions which determine nodal points in vibrating bronze objects. We may regard the spouting bowls as a specialized form of bell adapted to demonstrate the actions of sound upon liquids. The effects with liquids other than water are not known. The bowls may have had a utilitarian purpose, for example to give an index of viscosity, or they may have been used to perform a sophisticated test for adulteration of some precious liquid.

The subject of standing waves is one of the most intriguing questions in physics. Looked at from one point of view, a standing wave is a product of the collision of two equal and opposite waves. There is a modern mathematical theory showing clearly that only certain wavelengths may exist in standing waves inside vessels. Perhaps the ancient Chinese had some empirical grasp of this theory.

A standing wave is extraordinary by any standards, for it balances the normal dispersive forces which would destroy it in most circumstances with other, peculiar, counteracting forces which give the wave continued cohesion and allow it to prolong its existence. A standing wave is therefore a profoundly apt model for ancient Chinese concepts of 'the mean', or 'following the Tao'. It is also an entity

OPPOSITE (19) A photograph taken by Cecil Beaton of a boy demonstrating a bronze spouting bowl at the Chinese Temple at North Hot Springs. The handles at either side are rubbed rapidly. As long as there is no grease on the hands, and the water is at exactly the right level in the bowl, a strange humming sound is given off and water spouts appear from standing waves set up in the liquid. Such spouts can apparently sport as high as 3 feet in the sign.

created entirely out of its surrounding medium without the addition of any other distinguishing substance, and is therefore a perfect example of what the Chinese believed all things to be: everything emanated from the Tao and dissolved back into the Tao, like a standing wave in a spouting bowl.

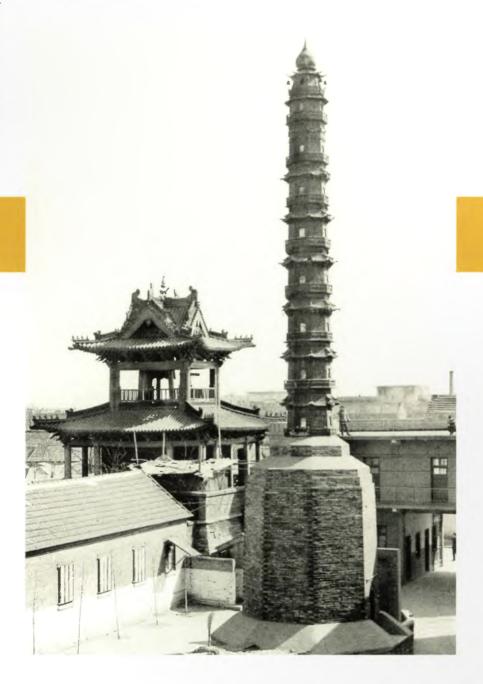

The Chinese believed the Tao to be 'the way of the Universe', which was always manifested from within rather than imposed from without by a god standing outside the Universe (a Western concept utterly alien to all Chinese thought). The spout spurting up from one of these bowls

is a form teased out of uniform and featureless fluid by the mysterious forces of resonance and sound – the cosmic forces which led to the creation and dissolution of all forms in that great sea, the Universe.

RIGHT (20) This cast iron pagoda in Jining, Shantung Province, was built in 1105. It was cast layer by layer in octagonal sections, and stands 78 feet high. There are several such cast iron pagodas in China, some even older than this one.

# CAST IRON FOURTH CENTURY BC

Blast furnaces for cast iron are now known to have existed in Scandinavia by the late eighth century AD, but many readers will be amazed to learn that cast iron was not widely available in Europe before 1380. The Chinese, however, practised the technique from at least the fourth century BC. What were the reasons for the Chinese superiority? There were a number of factors. China had good refractory clays for the construction of the walls of blast furnaces. The

Chinese also knew how to reduce the temperature at which the iron would melt. They threw in something which they called 'black earth', which contained much iron phosphate. If up to 6 per cent of phosphorus is added in this way to an iron mixture, it reduces the melting point from the normal 1130°C to 950°C. This technique was used in the early centuries, ceasing before the sixth century AD, when proper blast furnaces came into use which needed no such assistance.

Coal, which gave a high temperature, was used as a fuel from the fourth century AD, and probably earlier. One method was to put the iron ore in batteries of elongated, tube-like crucibles, and pack these round with a mass of coal which was then burnt. This had the extra advantage of excluding sulphur from the process. As late as the seventeenth century, unsuccessful attempts were being made in England to use coal for smelting iron.

Cast iron was at first the preserve of private speculators, who grew rich from it. But the Han Dynasty nationalized all cast iron manufacture in 119 BC so that the emperor could monopolize it. At about that time there were forty-six imperial Iron-Casting Bureaux throughout the country where government officials supervised the mass-production of cast iron goods.

The widespread availability of cast iron in ancient China had many side effects. It led to the innovation of the cast iron ploughshare in agriculture, along with iron hoes and other tools. Iron knives, axes, chisels, saws and awls all became available. Food could be cooked in cast iron pots, and even toys were made of cast iron. Cast iron statuettes of various animals have been found in Han Dynasty tombs dating between the second centuries BC and AD. Cast iron moulds for implements dating from the fourth century BC have also been discovered. Hoes and axes would have been cast in these, in either bronze or iron.

The expertise in cast iron enabled pots and pans to be made with very thin walls, impossible by other iron technology. One extremely important result was that salt could be mass-produced from evaporated brine, which can only be done in such thin pans. This in turn led the Chinese to exploit natural gas by deep drilling. This was in order to tap the energy from the burning gas to evaporate the vast quantities of brine required for the giant salt industry (which the Han Dynasty also nationalized

along with the iron industry in 119 BC). The salt and gas industries could not have existed without the cast iron industry.

In the third century BC, the Chinese discovered how to make a malleable cast iron by annealing (that is, by holding it at high temperature for a week or so). It was then not brittle, and would therefore not shatter if subjected to a violent shock. This meant that objects like ploughshares could survive striking large stones with considerable force. Cast iron had something of the elasticity of wrought iron, but with the much greater strength and solidity that came from being cast. It was almost as good as steel.

Swords became 50 per cent longer when made in iron. In 218 BC a man named Chang Liang tried to assassinate the emperor using an iron mace which weighed 160 pounds. Perhaps it was too heavy, for he did not succeed. Some of the ancient Chinese feats of casting iron are so impressive as to be almost unbelievable, even when the results are before our eyes. For instance, there is a cast iron

ABOVE (21) The largest single piece of cast iron from ancient China, and still one of the largest such objects in the world: the Great Lion of Tsang-chou in Hopei Province, erected in the year 954 by the Emperor Shih Tsung in commemoration of his campaign against the Liao Tartars. It weighs about 40 tons, and stands 20 feet high and 16 feet long. It is not solid: its thickness varies from 8 inches to only 1½ inches in places. The sections were poured at the same time, but some of the joints between them are weak. This gigantic object was made more than four hundred years before any cast iron was to be available in Europe.

pagoda seen in Plate 20 (page 44). This fantastic structure can be precisely dated to the year 1105. It is 78 feet high, cast storey by storey. There are several other such iron pagodas.

But these were by no means the biggest cast iron buildings made by the Chinese. The largest seems to have been the temple built on the orders of the Empress Wu Tse in 688 AD. This building, which no longer survives, was a staggering 294 feet high, based on an area of about 300 square feet. It was in the form of a three-storey pagoda, and atop the structure was a 10-foot cast iron phoenix covered in gold plate.

Perhaps the grandest cast iron structure of all was not actually a building. The Empress Wu Tse had an octagonal cast iron column built, called the 'Celestial Axis Commemorating the Virtue of the Great Chou Dynasty with Its Myriad Regions'. It was built in 695 AD upon a base of cast iron 170 feet in circumference and 20 feet high. The column itself was 12 feet in diameter and rose 105 feet in the air; on top was a 'cloud canopy' 10 feet high and 30 feet in circumference. On top of this in turn stood four bronze dragons each 12 feet high supporting a gilded pearl. We have a record of the amount of metal used in this construction -2.000.000 catties, which is about 1325 tons. The largest single cast iron object ever made (the pagodas were obviously not a single piece) was erected on the orders of the Emperor Shih Tsung of the Later Chou Dynasty in commemoration of his campaign against the Tartars in 954 AD. This extraordinary object, 20 feet tall, still stands and is known as the Great Lion of Tsang-chou. It is not solid, but its walls vary from 11/2 to 8 inches in thickness. It is reproduced in Plate 21 (page 45).

# THE DOUBLE-ACTING PISTON BELLOWS

FOURTH CENTURY BC

The double-acting piston bellows was a pump for air or fluids which enabled a continuous stream to be expelled. It was the capacity to provide continuous blasts of air which was a crucial factor in enabling the Chinese to achieve their superiority in metallurgy for so many hundreds of years. We do not know who invented the double-acting piston bellows, or exactly when it appeared. But it seems to have been

widespread by the fourth century BC, so that we can probably safely place its invention in the fifth at least. It appears to be referred to in the great philosophical classic of Lao Tzu as follows:

Heaven and Earth and all that lies between, Is like a bellows with its tuyère [nozzle for the blast];
Although it is empty it does not collapse,

And the more it is worked the more it gives forth.

The most conservative estimate dates Lao Tzu's book to about the fourth century BC, though the traditional dating is the sixth. Either could be correct. The third line is the crucial one, since it seems to refer to the continuous action of the double-acting piston bellows, which is a bellows that indeed does not collapse.

We see a double-acting piston bellows in Plate 22 (below), and in Figure 4 (opposite) we see a diagram of how it works. It is really a most simple but ingenious invention. A piston is pushed in and pulled out of a rectangular box, which acts as a cylinder. Feathers or folded pieces of soft paper are wedged round the piston to make sure that it is both airtight and lubricated in its passage. (These are the ancestors of modern piston-rings.) There is an inlet valve at each end of the box. When the piston is being pulled, air is sucked in from the far end. When

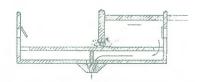

RIGHT (22) A late-eighteenthcentury painting showing a portable double-acting piston bellows in use by a travelling tinker. (Victoria and Albert Museum, London.)

it is being pushed, air is sucked in from the near side. (See 'A' and 'B' in the diagram.) In both inward and outward strokes, air is sucked into the cylinder; and in both cases air in the portion being compressed (that on the other side of the piston) is pushed into a side chamber where it is then expelled through the tuyère, or nozzle. The device is so simple that it is difficult to understand why Westerners never invented it. It could provide blasts not only of air but of liquids, and an example of the latter is given in the account of the flame-thrower (page 254).

The earliest published pictures of double-acting piston bellows are found in a quaint book of 1280 entitled *Book of Physiognomical*, *Astrological and Ornithomantic Divination according to the Three Schools*.

In the West in ancient times, single-acting pumps were certainly known from at least the second century

ABOVE (FIG. 4) A cut-away diagram of the double-acting piston bellows. A lengthwise section shows the piston being pulled out (to the right), compressing the air within the right-hand chamber and forcing it out of the nozzle at the bottom. When the piston is pushed in again, air is compressed in the chamber at the left, and is forced from the nozzle once more. The feathers shown are used to lubricate the movement of the piston while at the same time sealing off the air around its edges. The bellows is double-acting; whether the piston is being pushed or pulled it compresses air in alternate chambers, so that air rushes continuously from the nozzle. The nozzle has a valve like a swinging door, which here is seen pushed to the left; on the in-stroke of the piston it swings back to the right.

LEFT (23) Ulrich Hausmann, an expert on Chinese rural architecture, found this double-acting piston bellows in use in a farmhouse kitchen in Feng Huo village near Sian, and persuaded the housewife to step aside for a moment while he took the photograph. The bellows is in the enclosed box in the foreground, its wooden handle on the left. It provides a blast to keep the oven fire glowing, on this occasion for the preparation of traditional steamed bread.

BC; and syringes go back to indistinct antiquity, having been used for embalming in Egypt. But these were force-pumps which ejected air or liquid only in the outward stroke. The double-acting air bellows reached Europe, presumably from China, in about the sixteenth century. In 1716, J.N. de la Hire turned the principle to use with liquid for the first time in the West in a double-acting water pump.

### THE CRANK HANDLE

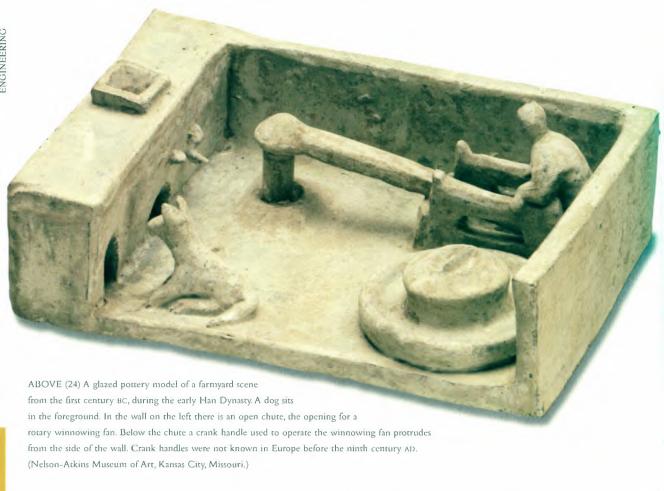

SECOND CENTURY BC

If you want to turn a wheel which is mounted in place for some mechanical purpose, then it is silly just to push the wheel round. The obvious thing to do is to stick a rod into the side of the wheel, use that as a handle, and turn it. This is known as a crank handle. But no one ever thought of it until the Chinese adopted the idea in the second century BC.

The Chinese invention of the crank handle was for use on their rotary winnowing machine (page 24), which was crucial to agriculture. (A winnowing machine with a crank handle may be seen in Plate 8 (page 24).) It was only then that sticking a rod at right angles into the side of a wheel was seen to be useful as a handle to turn the wheel. Not for eleven hundred years would the same idea occur to Westerners.

The only other people who came close to the invention of the crank handle were the ancient Egyptians. They had a kind of oblique proto-crank as early as 2500 BC, used for a primitive hand drill. It featured a slanted handle at the top for turning, but was not attached to a wheel, nor was it at right angles.

The Chinese used the crank also on well-windlasses, querns, mills and the many machines used in the silk industry. The earliest published picture of a crank handle appeared in Wang Chen's *Treatise on Agriculture* in 1313. But the oldest surviving depiction of a crank handle is on a miniature pottery farmyard

model found in a Han Dynasty tomb, dating from about the first century BC (see Plate 24 (above)). The oldest European evidence for the crank handle is a picture of one on a rotary grindstone in the Utrecht Psalter, a manuscript of about 830 AD.

## THE 'CARDAN SUSPENSION', OR GIMBALS

SECOND CENTURY BC

The 'Cardan suspension', or gimbals, takes its usual name from Jerome Cardan (Girolamo Cardano, 1501–76, who is also mentioned in the section on mathematics (pages 155–6). But Cardan neither invented the device nor claimed to have done so. He merely described it in his very popular book *De Subtilitate* (1550). The gimbals appeared in Europe as early as the ninth century AD) but it was invented in China by the second century BC at the latest.

This invention is the basis of the modern gyroscope, making possible the navigation and 'automatic pilots'

taken for granted in modern aircraft. Anyone who has been fortunate to enter a nineteenth-century gypsy caravan will have noticed affixed to the walls the brass gimbals that hold lamps which remain upright no matter how violently the cart may jolt on the road. These interlocking brass rings can be moved around as much as you like, but the lamp suspended in the centre never turns over. This is the basic idea of the 'Cardan suspension'. A series of rings inside one another are each joined at two opposing points, enabling them to twist and turn freely. Consequently, if a heavy weight, such as a lamp, is positioned upright in the centre, it will remain upright. Whatever motions might occur to the rings around it will be taken up by the rings themselves, leaving the lamp unmoved. By the eighteenth century, Chinese mariners were using a gimbal-mounted compass. A ship's magnetic compass mounted in this way was free of disturbance by waves.

The earliest textual reference to the gimbals which has been found is in a poem called *Ode on Beautiful Women*, composed about 140 BC, by Ssuma

Hsiang-Ju. It describes a seduction scene, and among the bedclothes, hangings, furniture and so on, the poet mentions 'the metal rings containing the burning perfume'. The supposed inventor of the gimbals was Fang Feng, though his identity is uncertain. More than three centuries later, about 189 AD, the clever mechanic Ting Huan was given credit for inventing the gimbals a second time. A book called *Miscellaneous Records of the Western Capital* records:

Ting Huan ... also made a 'Perfume burner for use among Cushions', otherwise known as the 'Bedclothes Censer'. Originally such devices had been connected with Fang Feng but afterwards the method had been lost until Ting Huan again began to make them. He fashioned a contrivance of rings which could revolve [in all three dimensions], so that the body of the burner remained constantly level, and could be placed among bedclothes and cushions. So it was given the name of Bedclothes Censer.

Ting Huan was connected also with the invention of the zoetrope, or 'magic lantern' (see page 98).

The gimbals turns up throughout Chinese literature after this point. In 692 AD the Empress Wu Hou was presented with 'wooden warmingstoves which, though rolled over and over with their iron cups filled with glowing fuel, could never be upset'. A book of 1734 called *Topography of the West Lake Region of Hangchow* mentions that 'interlocking pivots' were mounted inside paper lanterns which were then kicked and rolled along the streets without the lamps inside being put out. They were known as rolling lamps.

The various gimbals constructions had over the centuries such colourful names as perfume balls, globe-lamps, silver bags, rolling spheres and perfume baskets, and they were regularly used in annual processions as symbols of the moon carried in front of an undulating dragon (see Plate 26 (page 52)).

The gimbals reached Europe after eleven hundred years. And eight hundred years after that, the famous

LEFT (25) A Photograph of the interior of a brass Tibetan globelamp. The lamp is suspended by four separate rings, by which it is always held upright whichever way the lamp turns - even if it is upside-down. The outer cover is decorative and protective at the same time, and the lamp holds a candle-end in place of the wick it would originally have had. The use of interlocking rings to hold something upright in the centre is often called the 'Cardan suspension', after Jerome Cardan, a sixteenthcentury Italian scientist, but the Chinese invention predates him by seventeen hundred years. (Collection of Dr Joseph Needham.)

OPPOSITE (26) A lacquer screen with a decorative inlay showing children taking part in a dragon procession. One child holds a globe-lamp, representing the Moon-pearl, in front of the dragon. Within the paper globe would have been a lamp, held upright by a gnubals made of bamboo rings, so that whichever way the boy daired the lamp would not be extinguished. (Collection of Dr Lu Gwei-Djen.)

scientist Robert Hooke and others adopted its principle in a new form, applying power from without rather than stabilizing a central element within, to formulate that Western invention, the universal joint. And it was this invention which resulted in the transmission of automotive power in contemporary motor cars. Perhaps today, as we drive, we should give a thought to how much we owe to that most unlikely of all sources of mechanical progress in mass transportation, the 'Perfume burner for use among cushions'.

### MANUFACTURE OF STEEL FROM CAST IRON

SECOND CENTURY BO

Since the Chinese were the first to produce cast iron, they were also the first to make steel from cast iron. This was fully under way by the second century BC at the latest, and eventually led to the invention of the Bessemer steel process in the West in 1856. Henry Bessemer's work had been anticipated in 1852 by William Kelly, from a small town near Eddyville, Kentucky. Kelly had brought four Chinese steel experts to Kentucky in 1845, from whom he had learned the principles of steel production used in China for over two thousand years previously, and had made his own developments.

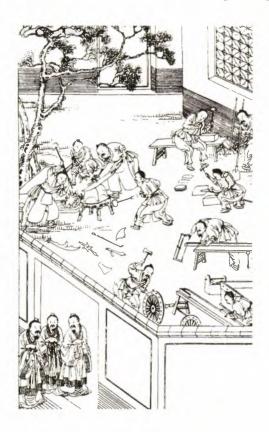

Iron, when melted and reformed into ingots, has a carbon content. This determines the nature of the metal as cast iron or steel, whichever the case may be. Cast iron is brittle because it contains a considerable quantity of carbon, perhaps as much as 4.5 per cent. 'Decarburization' is the removal of some or all of this carbon. Remove much of the carbon and you have steel; remove nearly all the carbon and you have wrought iron. The Chinese used wrought iron a great deal, most notably perhaps in building large bridges and aqueducts.

The Chinese invented the suspension bridge (see page 64), often constructing such bridges with chains

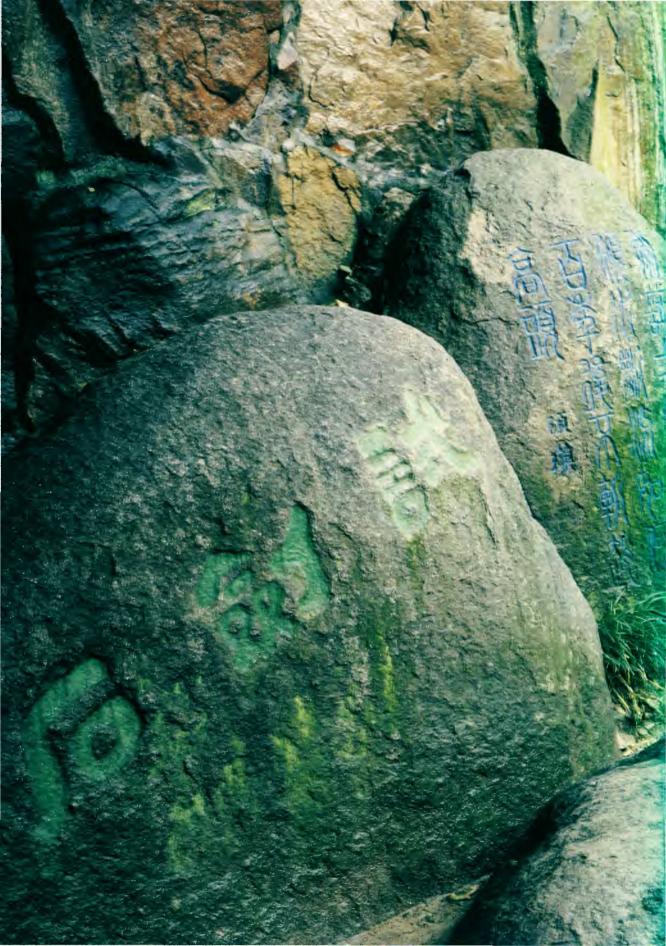

whose links were of wrought iron instead of plaited bamboo. Cast iron was called 'raw iron', steel was called 'great iron', and wrought iron was called 'ripe iron' by the Chinese. In order to make iron 'ripe', they clearly understood that the iron was losing a key ingredient, and they described this as 'loss of vital juices'. But, without knowledge of modern chemistry, they could not identify the ingredient as carbon.

The Chinese were not the first to make steel. But they did invent two particular steel manufacturing processes, of which taking the carbon out of cast iron was the first (the second is described on page 76). The first, the process of 'decarburization', was accomplished by blowing oxygen onto the cast iron ('oxygenation'). We read of this in the classic *Huai Nan Tzu*, which dates from about 120 BC.

Making steel by this means was also called 'the hundred refinings method', since it was often done over and over again, the steel becoming stronger each time. Swords made by this method were highly prized. The back of the sword, not having an edge,

ABOVE (27) A traditional Chinese print showing artisans at work in the Imperial Workshops. Those on the left are forging a steel sword on an anvil.

LEFT (28) At the bottom right of this photograph is 'Sword Testing Rock'. The King of Wu is said to have tested his steel sword two thousand, five hundred years ago by slicing through the rock with it. The Chinese characters carved and painted on adjoining rocks tell of the legend. Nearby is a Sword Pond, presumably where steel was once tempered in water. This is near Suchow, at Tiger Hill, known in ancient times as Sea Surging Hill. When the King of Wu was buried at this place, three thousand steel swords are supposed to have been placed in his tomb for use in the afterlife.

would often be made of the more elastic wrought iron, and the harder steel would be welded onto it to bear the cutting edge for a sabre. The carbon content of the steel could be adjusted depending upon how much oxygen was applied to the molten iron.

Generally speaking, steel with a higher carbon content is stronger, but then strength is traded against brittleness. Steel can have a carbon content of between 0.1 per cent and 1.8 per cent. The Chinese could only make empirical judgements on the qualities of steel obtained from certain numbers of refinings. If very soft steel was desired, they could go on blowing more oxygen in, removing increasing amounts of the carbon. And they practised the world-wide technique of quenching, whereby steel that is cooled instantly in a liquid when still either red- or white-hot preserves its inner metallic micro-structure which it would lose if allowed to cool slowly. On the other hand, cooling steel slowly (tempering) has other advantages. The Chinese were great masters at manipulating their iron materials in countless different ways to obtain the exact type of metal they required. In iron and steel technology, they led the world until modern times. And they were the first to make steel by taking the carbon out of cast iron. But then, no one else could have done so at the time, since cast iron existed nowhere else but in China.

### DEEP DRILLING FOR NATURAL GAS

FIRST CENTURY BC

The Chinese originated deep drilling by the first century BC and, with their traditional methods, were able to drill boreholes up to 4800 feet deep. The deep drilling for today's supplies of oil and natural gas is a development from these Chinese techniques.

The primary motive for deep drilling in China was the search for salt. Even as recently as 1965, 16.5 per cent of China's salt supplies came from brine pumped out of deep boreholes, making this source of supply second only to sea salt. In the beginning, the deep boreholes yielding brine were presumably artesian wells, with the brine spurting out of the wells under natural pressure. But, later, highly sophisticated methods of extracting the brine were developed for wells which had no artesian pressure. If the drilling went below the brine level, there would be vast supplies of natural gas, which was primarily methane. So the drilling for natural gas followed close on the

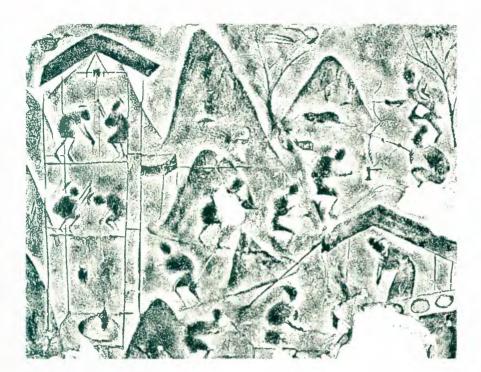

heels of the drilling for brine and essentially developed at the same time.

The sheer size of Chinese drilling equipment was remarkable. Derricks could rise as much as 180 feet above ground. One huge derrick photographed at the turn of the century may be seen in Plate 30 (see page 58). Tubes for extracting brine could be as much as 130 feet long and were inserted down the boreholes. At the top of a borehole would be a shaft dug with spades, reaching down to the level of hard rock, whether this was one foot or dozens of feet down. Once the rock was reached, stones with holes through the middle were stacked one on top of another up to ground level, all perfectly centred so that a long hole 8 to 14 inches wide extended down through them all from ground level to rock level. Then, the drilling would begin. A drill would be suspended by bamboo cables from a derrick. Thanks to the advanced state of the iron industry in China (see the account of the invention of cast iron, page 44), cast iron drilling bits were available. These would be dropped onto the rock, and any depth from 1 inch to 3 feet a day might be drilled. The drilling of a truly deep borehole often took years. The only power used for drilling was manpower: men jumped onto a lever to raise the bit and jumped off to let it crash down again. They did this rhythmically for hours on end.

The bamboo cables were made of strips 40 feet long. A single-strength cable would be used down to 1500 feet, but at depths greater than that, the cable was of double thickness. The tensile strength of hemp rope is 750 pounds per square inch, whereas that of bamboo is nearly 4 tons per square inch, equal to some steel wire. The bamboo was also so flexible that it could easily be wound up round the borehead winding drum. Bamboo cables had the added advantage of becoming tougher when wet, the opposite of rope.

It has been remarked that because Europe had no material equivalent to bamboo, and because using hemp ropes as cables for drill bits would have been like drilling with a rubber ball on the end of a piece of elastic, Europeans could not have developed deep-cable-drilling techniques even if they had wanted to.

When drilling commenced for the day, the cable was lowered by hand very gently until a slight tremor indicated that the bottom had been reached. The cable could not be at all slack, so that even if the drill bit were thousands of feet down, the drilling foreman could adjust its height by inches using a device called

LEFT (29) A rubbing from a Chinese tomb of about the first century AD. On the left may be seen a derrick for deep drilling for brine deposits; four men are hoisting up a bucket full of brine within the three-storey derrick while another bucket descends. In the background is a hunting scene in the mountains.

a 'pounding regulator', which manipulates a loop made at the top of the drilling cable. Two kinds of bit were traditionally used. The larger was 10 feet long and weighed over 300 pounds. It was used to pound the rock and widen the hole made by the smaller bit. The smaller bit weighed only a few dozen pounds.

Large numbers of men were not needed to do the drilling. Shallow wells needed only two men to jump on the lever board, whereas four to six men sufficed for deep wells. With a typical 12-foot lever, the bit would be raised to a height of about 2 feet, and then let fall. But lest the hole not be even and round, a worker stationed at the mouth of the well twisted the cable at each drop so that the drill bit would strike at a slightly different angle each time. By rotating the bit in this way, an even hole was produced.

Extremely ingenious devices were developed for fishing out of boreholes anything that might get stuck or tangled. These things would be dealt with thousands of feet underground with relative case. Other devices were invented called 'jars', which prevented the jarring of the derrick and platform every time the drill hit the rock.

The detritus left from several successive drill smashes would be removed by suction through hollow bamboo tubes with leather valves at the end; the pumps derived from the double-acting piston bellows described on page 46. The rock chips would

either be mixed with water poured down the well (in the early stages of drilling) or would mix naturally with water which was seeping into the borehole, so that the rubble would be brought up as slush.

The boreholes were lined with bamboo tubing. These had male-female joints and were watertight. Water seepage was thus prevented when drilling, except at the bottom. And when brine was reached, the brine could thus be extracted without being diluted by seeping fresh water from higher levels. When extracted from the wells, the brine would be raised several feet above ground level and was distributed for miles all round in an elaborate network of bamboo piping. Huge cast iron evaporation pans were set up, into which the brine would be poured. Heat would be applied under the pans, and the brine vigorously boiled for long periods. So vast was the amount of salt produced by this enormous industry that the province of Szechuan, known anciently as Shu, enjoyed several periods of independence from central government on the basis of its self-sufficiency in deep-borehole salt supplies.

Although the salt was sometimes evaporated by fires burning either wood or coal, this was a more expensive way than using natural gas fires. It was cleverer to use the natural gas from the same borehole or an adjoining one to heat the pans, and as many as 5100 salt pans are reported to have been heated by the

natural gas from a single well (the details of the use of natural gas as a fuel are recounted on page 89).

How many and how deep were the Chinese boreholes, whether for brine or for natural gas? Brine could not be found at less than 100 feet deep, and most of the boreholes had to be sunk to at least 600 feet. The majority of them were to depths averaging 3000 feet and the deepest recorded went to 4800 feet. There are more recent boreholes to 9600 feet, but we cannot be certain whether any of these deeper wells were drilled entirely by the traditional drilling technology or were assisted by imported Western technology, so the claims for the traditional drilling technology stop at a conservative 4800 feet.

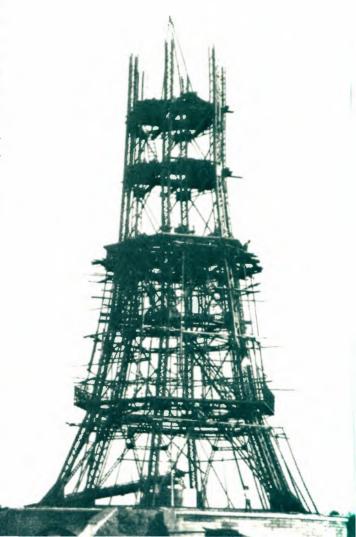

As for the numbers of deep boreholes, there were hundreds of them. An imperial edict of 1089 limited the number of them in the prefecture and province of Ch'engtu alone to 160 wells. An earlier tally said that in six districts of Tzu-chou there were 157 wells in working order and 50 plugged by government officials as a penalty for tax evasion. The salt industry was supposed to have been nationalized in the second century BC, and entrepreneurs continually tried to conceal their wells by removing the derricks before government inspectors came along. And without signs on the surface, who is going to spot a hole a few inches across with a stone placed over it, even if it does extend downwards 3000 feet? But the government 'revenuers' were as assiduous in hunting down bootlegging brine drillers as their counterparts have been in modern times in looking for illicit stills of moonshine whisky in the Appalachian Mountains of Kentucky and Virginia.

One hotbed of tax evasion in the eleventh century was the district of P'ei-ch'eng, where, out of 55

RIGHT (30) A previously unpublished photograph taken in about 1900, showing what is apparently a huge derrick for deep drilling. The location is unrecorded.

boreholes, 45 were plugged by 'revenuers' who found them out. In 1095, a complaint to the emperor said: 'In the prefecture and province of Ch'engtu all the brine boreholes are plugged up, and because of their closure thousands of families are unemployed.'

The first information in Europe about Chinese drilling techniques seems to have arrived in garbled form in the seventeenth century through Dutch informants. But the first full description of the Chinese system sent to Europe was in the form of letters written in 1828 by a French missionary named Imbert. His account was discussed in 1829 by an incredulous French scientific society; Imbert then wrote another letter giving further details and insisting that it was indeed possible to drill deep holes with bamboo cables (Europeans had been attempting boreholes with linked rods, which were not working very well). Imbert said he had seen, with his own eyes, great wheels drawing up tubular buckets of brine; the wheels measured 40 feet in circumference and were turned fifty times, showing that depths of 2000 feet

LEFT (31) A photograph taken by Cecil Beaton during the Second World War, showing a traditional Chinese deep-drilling derrick over the well head of a brine and/or natural gas well.

could indeed be reached. A French engineer, Jobard, had tried the Chinese method as soon as Imbert's first letters had arrived. Various details of the Chinese system were also adapted for linked-rod drilling, bringing greater success.

By 1834 Chinese drilling techniques had become properly established in Europe for brine drilling, and by 1841 for oil drilling. In 1859, a well exclusively for oil was drilled at Oil Creek, Pennsylvania, by Colonel E.L. Drake, using the Chinese cable method. The oil was to be used for fuel, as had been the case in China for some time (see page 89). Drake and similar oil drillers in America may have obtained knowledge of the system not from France but from the hordes of Chinese indentured labourers used to build the railways in nineteenth-century America. In America, the method for oil drilling prior to the advent of steam power ('kicking her down', as it was called), was exactly the same as the Chinese technique of bowstring drilling which had derived from the men jumping on

and off a lever. And even the modern rotary bits seem to have partial Chinese ancestry. In short, Western deep drilling was essentially an importation from China, and the modern oil industry is founded on Oriental techniques nineteen hundred years in advance of the West.

## THE BELT-DRIVE (OR DRIVING-BELT)

FIRST CENTURY BC

The belt-drive or driving-belt transmits power from one wheel to another, and produces continuous rotary motion. It existed as early as the first century BC in China. It is attested by a passage in Yang Hsiung's book, *Dictionary of Local Expressions*, of 15 BC. It was developed for use in machines connected with silk manufacture, especially one called a quilling-machine, which wound the long silk fibres onto bobbins for the weavers' shuttles. These machines featured a large

wheel and a driving-belt and small pulley. The machines are mentioned again in the book *Enlargement of the Literary Expositor* compiled between 230 and 232 AD.

The driving-belt was essential for the invention of the spinning-wheel, which is described separately (page 134). The belts could run not only round normal wheels with rims, whether grooved or not, but also round rimless wheels. A rimless spinning-wheel may sound a contradiction in terms, and the use of a driving-belt with rimless wheels might at first seem an impossibility. But in fact a cat's cradle of fibres strung between wheel spokes which protrude slightly or exist in two sets placed in alternation can create an entirely adequate nexus for a belt. Needham photographed just such an archaic spinning-wheel in use in Shensi in 1942. It is extraordinary to think that the spinningwheel of 1270 survives unchanged into the modern era. Yet another Chinese technique of using a drivingbelt with a rimless wheel is to mount grooved blocks at the ends of the spokes, and run the belt through the successive grooves (see Plate 87 (page 135)).

A refinement of the driving-belt is the chain-drive, invented in China in 976 AD, and described on page 81. A chain-drive is essentially a driving-belt which instead of being solid is a chain into the links of which fit sprockets on the wheels around which it is wrapped.

The driving-belt was apparently imported to Europe as part of the technology of quilling-wheels and spinning-wheels introduced into Italy by travellers returning from China. The oldest actual representation of a driving-belt in Europe dates from 1430, on a rotary horizontal grindstone. Driving-belts remained extremely rare in Europe until the eighteenth and nineteenth centuries, indicating that Europeans did not appreciate the potential of this particular element of the Chinese textile machines for other purposes to any significant degree for more than three centuries. Flat belts and wire cables as driving-belts in Europe only began to be used in the nineteenth century.

### WATER POWER

FIRST CENTURY AD

The harnessing of water power for the operation of blast furnace bellows commenced in 31 AD. The official history of that time recorded how Tu Shih, Prefect of Nanyang, invented a water-power reciprocator for the casting of iron agricultural implements: 'Thus the people got great benefit for

little labour. They found the "water-powered bellows" convenient and adopted it widely. Li Hsien commented on this passage in 670: 'Those who smelted and cast already had the push-bellows to blow up their charcoal fires, and now they were instructed to use the rushing of the water to operate it...'.

In the account of the double-acting piston bellows (page 46) we see that such bellows existed from the fourth century BC, so now the same machine was evidently being worked by water mills instead of by human muscle power. The water-powered bellows remained popular round Nanyang for two centuries. The *History of the Three Kingdoms* (290 AD) then continues the story:

Han Chi, when Prefect of Lo-ling, was made Superintendent of Metallurgical Production. The old method was to use horse-power for the blowing-engines, and each picul [about 130 pounds] of refined wrought iron took the work of a hundred horses. Man-power was also used, but that too was exceedingly expensive. So Han Chi adapted the furnace bellows to the use of ever-flowing water, and an efficiency three times greater than before was attained. During his seven years of office, iron implements became very abundant. Upon receiving his report, the emperor rewarded him and gave him the title of Commander of the Metal-Workers.

This occurred around the year 238 AD. About twenty years after that, considerable improvements were introduced to the machines by the inventor Tu Yü, and water-powered bellows continued through each century to spread more and more widely throughout China. The use of a piston-rod and driving-belt by Wang Chen in his version, described in his *Treatise on Agriculture* of 1313, is discussed in the account of the essentials of the steam engine (page 72).

As for the use of water power by the metallurgical industry in Europe, this did not occur until the twelfth century when forge-hammers were thus powered. But the use of water power for bellows did not begin until the thirteenth century — a time-lag of twelve hundred years. This innovation by the Chinese in harnessing water power for industrial processes on a large scale was one of the most significant breakthroughs in energy supply before modern times. It was one of the major steps towards the Industrial Revolution.

ABOVE (33) A treadle-operated square-pallet chain pump being used in contemporary China for raising water for trrugation.

### THE CHAIN PUMP

FIRST CLASTICKY AD

One of the inventions of greatest utility which has spread from China throughout the world, so that its origins are no longer realized, is the square-pallet chain pump. As may be seen in the accompanying illustrations, it consists of an endless circulating chain bearing square pallets which hold water, earth, or sand.

This pump can haul enormous quantities of water from lower to higher levels. The optimum angle of slope at which the chain of pallets can be laid out is about 24°. So, depending on how well the pallets were fitted to avoid leakage and on the sturdiness of the machine as a whole, the height that water can be raised by a single pump is about 15 feet.

By medieval times in China, the pumps had been adapted for use as conveyors of earth or sand rather than just water. They were thus the first conveyor belts.

We do not know who invented the chain pump, or exactly when. Although it may have existed some centuries earlier, we can take as its time of origin the first century AD. The philosopher Wang Ch'ung refers to its existence about 80 AD in his book *Discourses Weighed in the Balauce*. Considerable improvements were made to the design during the next century. We know this from an account in the imperial history of the time, which discusses the lack of water in the capital, Loyang. The history tells us that the famous eunuch minister Chang Jang (died 189 AD) ordered various improvements for Loyang from the engineer Pi Lan:

He further asked Pi Lan ... to construct square-pallet chain pumps and suction pumps, which were set up to the west of the bridge outside the Peace Gate to spray water along the north-south roads of the city, thus saving the expense incurred by the common people [in sprinkling water on these roads and carrying water to the people living along them]....

Chain pumps had achieved a standard form in China by 828. The imperial history for that year records:

In the second year of the T'ai-Ho reign-period, in the second month ... a standard model of the chain-pump was issued from the palace, and the people of Ching-chao Fu were ordered by the Emperor to make a considerable number of the machines, for distribution along the Cheng Pai Canal, for irrigation purposes.

The pumps were used for civil engineering works and for draining all sorts of sites, as well as for irrigation and the supply of drinking water. The pumps were so spectacular in their results that visiting dignitaries and ambassadors from neighbouring lands eventually adopted them in their own countries. By medieval times, Korea and Annam (Vietnam) had transformed their agriculture and irrigation by this means. In 1221, when the pumps were introduced by some visiting Chinese to the inhabitants of Turkestan, the locals exclaimed with delight, 'You Chinese are so clever at everything!'

The first European square-pallet chain pumps were made in the sixteenth century, modelled directly on Chinese designs. By the end of the next century, the British Navy had copied them from Chinese

ABOVE (34) A woodcut printed in Exploitation of the Works of Nature in 1637, showing two men working a square-pallet chain pump by treadles.

junks for use as bilge-pumps aboard ship. The pumps were introduced to America by the Dutchman A.E. van Braam Houckgeest, where he said they had 'proved of great utility'. And the conveyor-belt form was adapted for use in the eighteenth century by Oliver Evans for flour-milling. This led to the development of the modern grain-elevator. A sixteenth-century European dredger using buckets instead of pallets is the ancestor of all the drainage devices on belt conveyors used in modern mining and excavation work. And as recently as 1938, the classic square-pallet chain pump was reintroduced to the United States from China for pumping crystallized brine from the Great Salt Lake in Utah.

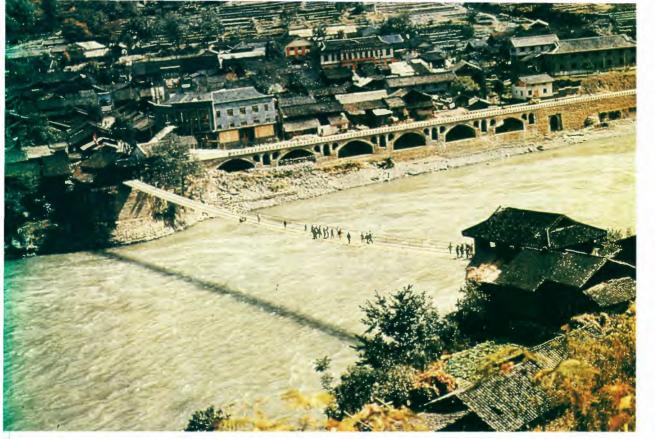

### THE SUSPENSION BRIDGE

FIRST CENTURY AD

Few structures seem more typical of the modern world and its engineering achievements than the suspension bridge. And yet, the sophisticated form of the suspension bridge, with a flat roadway suspended from cables, was unquestionably invented in China. And it is highly likely that the two more primitive forms of suspension bridge also originated there, the simple rope bridge and the catenary bridge (where the walkway or roadway is not flat but follows the curve of the cables).

The simplest form of 'suspension' bridge – if we can even call it that – is simply a rope thrown across a gorge. Probably from the very beginning, the technique used for getting the rope across was that still used later for elaborate suspension bridges – shooting it across, tied to an arrow. After the Chinese invention of the crossbow (see page 244) greater power would have been available for heavier cables over longer distances.

Climbing or scrambling along a single rope above a gorge can be dangerous, and is hard on the hands. An ingenious solution is still in use in some areas, such as the Tibetan–Chinese border. The rope is threaded through a hollow piece of bamboo before being attached, and the person merely hugs the bamboo and slides along the rope without burning his hands or straining himself unduly. A more sophisticated method is by a cradle attached to the bamboo tube. Cable bridges of liana vines are known in the Andes mountains of Peru, dating back to at least 1290, and Needham suspects that this may be one of the many

ABOVE (35) A well-known suspension bridge with a single span of 361 feet, at Lu-ting in Sikang. Although built as recently as 1705, it replaced an earlier bridge at the same spot. The suspension cables are wrought iron chains.

Chinese ideas to have spread to the New World across the Pacific.

Bridges of ropes and cables in China and Tibet evolved into multiple-cable bridges of various types. Sometimes three ropes or cables are stretched across together so that the person crossing can walk with his feet on two of them and hold a third above his head for balance. Or a woven walkway of matting is incorporated between the two bottom ropes or cables, to make the going easier. Another variation is to have a series of hanging straps by which the user pulls himself forward. All these and other variations occur in the area between China and Tibet, in the high mountains. A reference in the Chinese dynastic history for 90 AD appears to mention a suspension bridge which has planking and, hence, a proper platform upon which to cross:

There the gorges and ravines allow of no connecting road, but ropes and cables are stretched across from side to side and by means of these a passage is effected.

This reference is rather vague. The same dynastic history for 25 BC describes a harrowing Himalayan suspension bridge:

Then comes the road through the San-ch'ih-p'an gorge, thirty *li* long, where the path is only 16 or 17 inches wide, on the edge of unfathomable precipices. Travellers go step by step here, clasping each other for safety, and rope suspension bridges are stretched across the chasms from side to side. After 20 *li* one reaches the Hsien-tu mountain pass.... Verily the difficulties and dangers of the road are indescribable.

Fa-Hsien, the first Chinese Buddhist pilgrim to India, crossed this very bridge in 399 AD, and left this account of his experience:

Keeping on through the valleys and passes of the Ts'ung-ling mountain range, we travelled south-westwards for fifteen days. The road is

difficult and broken, with steep crags and precipices in the way. The mountain-sides are simply stone walls standing straight up 8000 feet high. To look down makes one dizzy, and when one wants to move forward one is not sure of one's foothold. Below flows the Hsin-t'ou Ho. Men of former times bored through the rocks here to make a way, and fixed ladders at the sides of the cliffs, seven hundred of which one has to negotiate. Then one passes fearfully across a bridge of suspended cables to cross the river, the sides of which are here rather less than 80 paces [400 feet] apart.

Cable bridges in China were most efficient when made of bamboo. The cables were made with a centre formed of the core of the bamboo surrounded by plaited bamboo strips made of the outer layers of the wood. The plaiting was done so that the higher the tension, the more tightly the outer strips gripped the

inner core. This led to the safety factor that it is the inner strands of a cable which snap first, rather than the outer strips which would otherwise unravel very fast. An ordinary 2-inch hemp rope can stand stresses of only about 8000 pounds per square inch, but bamboo cables can stand a stress of 26,000 pounds per square inch. Ordinary steel cables will only take twice as much stress (56,000 pounds), so bamboo is remarkably strong. (Modern steel alloys such as used in the Golden Gate Bridge at San Francisco can take stresses of 256,000 pounds per square inch.)

The most famous Chinese suspension bridge is a catenary bridge (which has a roadway following the curves of the cables rather than hanging flat): the An-Lan Bridge at Kuanhsien in Szechuan. It has a total length of 1050 feet, composed of eight successive spans, and there is not a single piece of metal in the entire structure. An account of a traveller crossing it in 1177 describes only five spans at that time. It has planking on which to walk, originally 12 feet wide but today only 9 feet wide, and it is believed to have

RIGHT (37) A previously unpublished photograph of the famous An-Lan Bridge at Kuanhsien in the southern province of Szechuan, taken by Ernst Boerschmann in about 1900. Composed of eight successive spans, this catenary suspension bridge has a total length of 1050 feet. The platform is wood planking and the cables are made of rope.

been built in the third century BC by Li Ping. It may be seen in Plate 37 (opposite).

The true suspension bridge became possible with the invention of the iron-chain suspension technique. As described elsewhere (page 53) the Chinese were in advance of the whole of the rest of the world in their iron and steel technology. Needham believes that they applied wrought-iron chains to suspension bridges by the first century AD. Massive stone abutments were built to contain the chain ends.

From these chains it became possible to suspend the planking gangway increasingly away from the catenary curve of the chains themselves so that it tended towards being a flat surface. The greatest span of which a Chinese iron-chain suspension bridge is known to have been capable is about 430 feet, at Lu-shan in Szechuan. The longest such bridge which still exists is 361 feet, at Lu-ting in Sikang. Its chains are embedded 40 feet deep into the stone pillars on both sides. The bridge may be seen in Plate 35 (page 65). In its present form, it was built in 1705, but it is presumed to have replaced earlier versions on the same site. It was the scene of a major incident during the Communist Army's Long March, when they successfully stormed the bridge under heavy fire despite the fact that its planking had largely been removed.

We have an interesting and vivid description written in 1638 by Hsü Hsia-K'o of a bridge in south-western Kweichow Province:

The P'an Chian bridge is held by iron chains which connect the cliffs on the eastern and western sides of the river, a distance of 150 feet. The warp so made has a weft of planks. The cliffs themselves are about 300 feet high and between them a swift raging stream of water, of unfathomed depth, rushed along. In earlier years ferry boats were often in grave danger of capsizing, whereupon people tried to span it by a stone structure, but they failed. Then in the fourth year of the Ch'ung-Chen reign-period the present Governor, then a judge, Chu Chia-Min, asked Major Li Fang-Hsien to build a suspension bridge. So now several tens of great iron chains are suspended from towers on each bank, and on them two layers of boards, about 8 inches thick and more than 8 feet long, are laid. The bridge looks flimsy and unsubstantial, but when people tread on it, it is as immovable as a mountainpeak; daily hundreds of oxen and horses with heavy loads pass over it. Each side of the bridge is protected by a high iron railing woven with smaller chains. On each bank there crouch two stone lions, 3 or 4 feet high, which clench these railing-chains tightly in their mouths.

An old engraving of this bridge was published in 1665 in *Record of the Iron Suspension Bridge* by Chu Hsieh-Yüan. In the foreground is 'the stone of weeping', a memorial to all those who lost their lives trying to cross the river before the bridge was built in 1629. This bridge remained in service until 1939, when it was replaced with a steel suspension bridge, destroyed by the Japanese only a year later. In 1943, a new steel suspension bridge was erected half a mile downstream, which is still in use.

Chinese regions tend to have different types of bridge. Suspension bridges are found mostly in the south-west of China. Arch bridges (see page 77) are found mostly in the north. Only those who travel into the wilder and more remote parts of south-western China are likely to see the ancient suspension bridges which still exist there in profusion. Since the origins of suspension bridges are somewhat vague, with no precise date and no actual inventor, we may take the date of the first century AD, when iron chains were applied to bridges, as a highly conservative date for the earliest Chinese suspension bridges capable of carrying vehicles (though probably this happened at least four centuries earlier, using only bamboo cables, at Kuanhsien).

The first Western suspension bridge capable of carrying vehicles was built in 1809 across the Merrimac River in Massachusetts (span 244 feet). In the case of this invention, we can trace its transmission fairly well. The suspension bridges of Kweichow, such as the P'an Chian Bridge just described, came to the attention of the Jesuits and other Westerners who visited China in the seventeenth century. In 1655, Martin Martini described an iron-chain bridge over a river in Kweichow, which was incorporated in Blaeu's great New Chinese Atlas of that date.

An earlier mention of suspension bridges seems to have reached the European designer Faustus Verantius, for he proposed a sort of suspension bridge of linked rods in 1595. The Chinese also had such bridges of linked rods. But it was Martini's remarks which brought wide attention to suspension bridges in

Europe. The subject was picked up two years later, in 1667, by Athanasius Kircher, in his *China Illustrata*. Kircher wrote:

When several people cross the bridge at one time it moves and sways and oscillates up and down in such a way as to evoke in them no small fear of the danger of falling off; yet I find it impossible sufficiently to admire the skill of the Chinese engineers, who have executed so many and such arduous works for the greater convenience of wayfaring men.

However, European engineers seem to have done nothing about this for nearly a century. Then the first Western iron-chain suspension bridge, the Winch Bridge, was built in 1741 over the Tees in England. It had only the cables, and no deck for vehicles. The same was true of some small bridges which were built about that time. But since the first Western suspension bridge capable of carrying traffic was not constructed until 1809, the Chinese are seen to have been at least 1800 years in advance of the West, if not indeed 2200 or more, in this particular field.

### THE FIRST CYBERNETIC MACHINE

THIRD CENTURY AL

By the third century AD at the latest, the Chinese had a fully operational, navigational 'cybernetic machine', using the principles of feedback. It was called the 'south-pointing carriage', but had no connection with a magnetic compass. It was a large carriage, 11 feet long, 11 feet deep, and 91/2 feet wide, surmounted by a jade statue of an 'immortal' - a sage who had achieved immortality. The figure's arm was raised, pointing ahead, and it always faced towards the south, no matter which way the carriage turned. Even if the road were circular, the jade figure would rotate, keeping the finger pointing in the same direction. How was this possible in the third century AD? This machine may have been invented even earlier, indeed, as much as twelve hundred years earlier. An official history for 500 AD describes how:

The south-pointing carriage was first constructed by the Duke of Chou [beginning of the first millennium BC] as a means of conducting homewards certain envoys who

had arrived from a great distance beyond the frontiers. The country was a boundless plain in which people lost their bearings as to east and west, so the Duke caused this vehicle to be made in order that the ambassadors should be able to distinguish north and south.

If this information is correct, the invention would date from about 1030 BC. But Needham suspects that the word 'carriage' was inserted in this account by scribes, and that what is being described is a 'south-pointer', that is, a compass, in which case the origin of the compass, described on page 162, must be pushed back even further.

The next person credited with building a south-pointing carriage is the astronomer and scientist Chang Heng, about 120 AD, although this is also regarded by Needham as doubtful. The only date which he is prepared to accept with certainty is the middle of the third century AD, with the famous engineer Ma Chün as the builder (and, thus, the inventor). The drawing of a pointing figure of jade, taken from the *Universal Encyclopedia* of 1601, was copied from a print of 1341, and is reproduced in Plate 39 (page 72).

If the machine did not use a magnetic compass, how did it work? The answer is that it had a train of differential gears, similar to those in a modern automobile. Perhaps the function of a differential gear should be explained as follows. When a wheeled vehicle is turning a corner the wheels on opposite sides of the vehicle are clearly going to need to turn at different rates since the near side is travelling a shorter distance than the far side. With a hand-cart or horse-drawn carriage, this may not pose such problems. But when a vehicle has power being applied to the axle to make the wheels turn, how is it possible for one wheel to be permitted to speed up a little, and the other slow down a little, on the same axle? This is made possible only by an ingenious combination of gear wheels and flywheels: the differential gear.

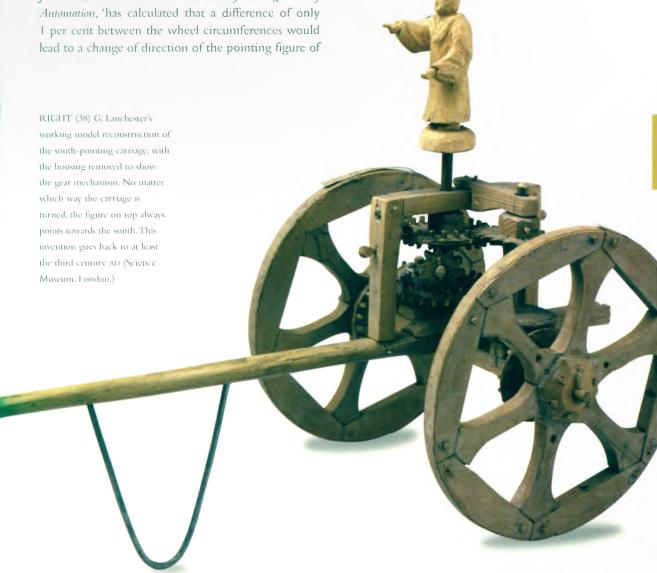

When Needham published his volume on mechanical engineering in 1965, he believed that the Chinese had invented the differential gear, and that it had made its first appearance in this south-pointing carriage. If the first south-pointing carriage were the one attributed to the Duke of Chou about 1000 BC, then the Chinese would indeed have been the inventors; but we must stay on the side of caution, and assume that the first south-pointing carriage was

made in the second or third century AD. In that case, we must credit the Greeks with inventing the differential gear, a fact which became known only in 1975, when Professor Derek Price published his book Gears from the Greeks. In this work Price wrote the definitive account of a Greek differential gear dating from 80 BC, which Price said 'must surely rank as one of the greatest basic mechanical inventions of all time'. And although a transmission of this invention from Greece and Rome to China was possible, it is equally possible that the differential gear was independently re-invented in China for the south-pointing carriage.

The precision needed in the construction of the south-pointing carriage almost defies belief. For the outside road wheels alone, Needham points out, J. Coales, in *The Historical and Scientific Background of Automation*, 'has calculated that a difference of only 1 per cent between the wheel circumferences would lead to a change of direction of the pointing figure of

as much as 90 degrees in a distance only fifty times that between the two wheels.' This was because the carriage would veer more and more to one side if one wheel were smaller (relative slip). So that for this south-pointing carriage, the size of the road wheels had to be accurate to a margin of error far less than one per cent, and a commensurate accuracy in size of gear wheels would have been necessary. This points to engineering of such a high order that we may well be justified in hesitating to apply the words 'ancient' and 'primitive' to it!

The south-pointing device was basically a reversal of the use of the differential gear in the modern

ABOVE (39) An old print of the jade figure on top of the south-pointing carriage, from the *Universal Encyclopedia* of 1601. It was redrawn from *Illustrated Record of Ancient Jade Objects* by Chu Te-Jun, published in 1341, which describes the south-pointing figure as 1.42 feet high and made of pale reddish-yellow jade.

automobile. Today, such gears are used to apply power to turn the wheels and make the vehicle move. But with the south-pointing carriage, which was pulled by animals, the power was transmitted from the wheels, and applied towards the continual adjusting of the position of the pointing figure. Thus it was the differential gear in the machine which turned the figure so that it always pointed to the south. And it did so just as the differential gear operates today, only in reverse.

There also remains evidence of a south-pointing boat, though few details of it survive. It was built during the Chin Dynasty (265-420 AD), and sailed round the palace gardens on the Ling-Chih lake. Needham speculates that it might simply have been navigated by means of a lodestone. But he adds: 'An

alternative would be that the boat was a paddle-boat (paddle-wheel boats certainly existed in China at this time), and that someone attempted to apply to its two wheels the same kind of device as had already been applied to the carriage. Probably no one will ever find out.' Whether this boat was or was not a water-borne version of the south-pointing carriage, the principles had already been developed to make it possible.

Needham has called the south-pointing carriage 'the first homeostatic machine in human history, involving full negative feedback. Of course, the driver had to be included in the loop. But as Coales has acutely pointed out, an attractive carrot held by the pointing figure might have replaced the human driver and closed the loop more automatically.' Although Needham has occasionally spoken of the south-pointing carriage as the first actual cybernetic machine, he has qualified this by saying: 'The south-pointing carriage would have been the first cybernetic machine had the actual steering corrected itself, as we could easily make it do today'.

### ESSENTIALS OF THE STEAM ENGINE

FIFTH CENTURY AD

The essential design of the steam engine, lacking only the crank-shaft, was invented in China before the steam engine existed. It was a water-powered flour sifting and shaking machine which operated in reverse mode to the later operation of the steam engine: instead of the piston of the steam engine working the wheels on a vehicle, the Chinese machine had wheels which were worked by rushing water in order to power pistons. The crank-shaft could not be incorporated in the Chinese machine because it is a Western invention which the Chinese never had. But it was not necessary.

The machines in question were south of the city of Ching Ming Ssu at the Buddhist monasteries of Loyang. They are mentioned in a book entitled Description of the Buddhist Temples and Monasteries of Loyang, dating from about 530 AD. These machines worked on the reciprocating principle of a piston being moved by a connecting rod attached to a crank (powered by a water wheel).

This principle came to be used more widely in connection with the metallurgical industry. A waterpowered device of this kind was found to be the most efficient and labour-saving way to work the giant bellows of blast furnaces. The first published picture of such a machine appeared in Wang Chen's *Treatise on Agriculture* in 1313. Needham has published a mechanical diagram of how the machine worked (reconstructed from details of the text of Wang Chen's book and other sources), and gives a mechanically accurate description of it.

Here is Wang Chen's own fourteenth-century description:

The design is as follows. A place beside a rushing torrent is selected, and a vertical shaft is set up in a framework with two horizontal wheels so that the lower one is rotated by the force of the water. The upper one is connected by a driving-belt to a smaller wheel in front of it, which bears an eccentric lug. Then all as one, following the turning of the driving-wheel, the connecting-rod attached to the eccentric lug pushes and pulls the rocking roller, and levers to left and right of which assure the transmission of the motion to the piston-rod. Thus this is pushed back and forth, operating the furnace bellows far more quickly than would be possible with man-power....

When Metallurgical Bureaux are established, they often spend a great deal of money and hire much labour to work the bellows, which is very expensive indeed. But by these methods [using water-power] great savings can be made. Now it is a long time since the inventions were first devised, and some of them have been lost, so I travelled to many places to explore and recover the techniques involved. And I have drawn the accompanying diagrams according to what I found, for the enrichment of the country by the official metallurgists and the greater convenience of private smelters.

Wang Chen also mentions the flour sifting and shaking (bolting) machine.

A book called *Topography of Anyang District* preserves an account from a now lost work called *Old Manual of Metallurgical Water-Power Technology* which states that these machines were introduced in the sixth century by the eminent engineer, architect and city planner Kao Lung-Chih, who was at the time Director of the Ministries Department. He must

have taken the idea of the Loyang flour machines and applied it to metallurgy. The lost work is even quoted as saying that the water wheels which he used were 1 foot broad and 7½ feet in diameter. He called the technique 'water power smelting'. This, then, was one of the secrets of Chinese metallurgical supremacy. For we know from another source that by driving the pistons from the smaller wheel on the machine, which spun fifteen times faster than the large drivingwheel, the pistons fanning the smelting fires could work at an enormous rate. The blast would have been continuous, since from the fourth century BC the Chinese had used the double-acting piston bellows for this purpose. Consequently, the Chinese had prodigious energies harnessed to provide fully automated continuous air blasts for their metallurgical operations by the sixth century AD. It is no wonder that this was the century which also saw the development of the steel co-fusion process. The excellent steel which the Chinese had been producing for several centuries previously provided the necessary bearings and parts to produce tolerance for such hard-working machinery.

It was seven hundred years before water power in Europe was to be harnessed for bellows, in the thirteenth century. In 1757, John Wilkinson patented a hydraulic blowing-engine which was essentially identical to that described by Wang Chen in 1313, except for the addition of a crank-shaft by way of refinement. In 1780, James Pickard patented a steam engine using essentially this apparatus in reverse, that is, power from the piston driving the wheel rather than vice versa. Pickard's patent forced James Watt (who was barred from this standard technique by not having the patent) to invent the sun-and-planet gear for his own steam engine. These European designs were all derived, through various intermediaries such as Agostino Ramelli (1588), from those of China. As for pistons driving wheels, rather than the other way round, Chinese stimulus was available separately there. Pistons driven by exploding gunpowder were tried in Europe on the idea, as Needham has put it, that 'the piston and piston-rod may be considered a tethered cannon-ball'. Since the Chinese invented both gunpowder and the gun (see pages 250) and 266), internal combustion as well as steam engines were partly inspired by the fact that a gun has a projectile which exactly fits the barrel and is expelled by force - further Chinese contributions to the ancestry of both engines.

### 'MAGIC MIRRORS'

FIFTH CENTURY AD

Those who like to think of China as a land of mystery are well served by the Chinese 'magic mirrors', which are some of the strangest objects in the world. They are known to go back to at least the fifth century AD, though their exact origins are unknown. About twelve hundred years ago, there still existed a book entitled *Record of Ancient Mirrors*, which apparently contained the secrets of these magic mirrors and their construction, but sadly it seems to have been lost for over a thousand years.

of prominent scientists attempted to discover their secret. It was a hundred years before a satisfactory theory of magic mirrors was formulated (by the British crystallographer Sir William Bragg) in 1932. These strange objects had defied the best brains in Europe for a century.

What exactly, then, is a magic mirror? On its back it has cast bronze designs – pictures, or written

What exactly, then, is a magic mirror? On its back it has cast bronze designs – pictures, or written characters, or both. The reflecting side is convex and is of bright, shiny polished bronze which serves as a mirror. In many conditions of lighting, when held in the hand, it appears to be a perfectly normal mirror.

However, when the mirror is held in bright sunshine, its reflecting surface

When magic mirrors came to the attention of the West in 1832, dozens

RIGHT & OPPOSITE (40) This is a typical example of a magic mirror. The microscopic irregularities on the apparently smooth reverse side of the mirror cannot be detected by the eye. However, when the mirror is held in the sun, so that a reflection of the sunlight is cast onto a dark wall by the seemingly smooth surface, the picture of cranes and trees and the two Chinese characters which have been cast in relief on the ornamented back of the mirror are miraculously visible as a projected image on the wall, as if the solid bronze had suddenly become transparent and the pattern had somehow

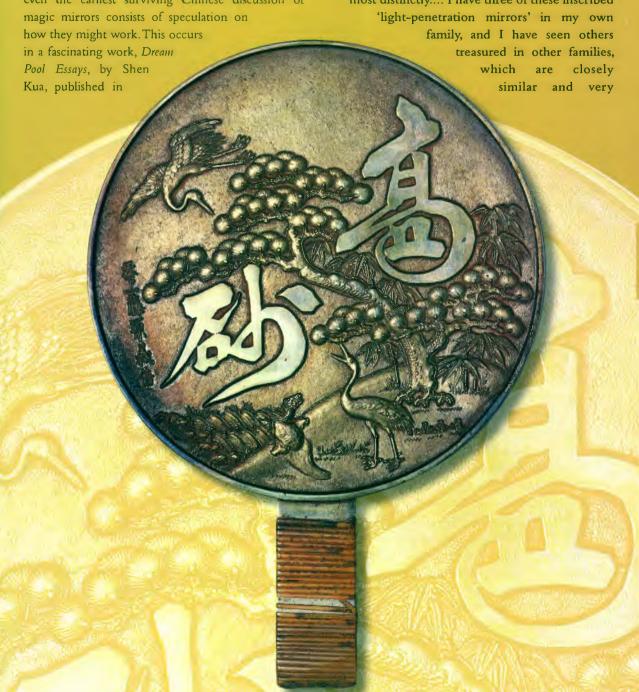

'passed through' the solid mirror and become visible in the wall reflection. The metallungical process by which this eerie and seeningly supernatural phenomenon is achieved was not scientifically explained in the West until 1932, although the Chinese have been making magic mirrors and keeping the technique secret for 1600 years. This particular example in bronze belonged to Joseph Needham and is Japanese, rather than Chinese. The Chinese written characters on this mirror (many of which are regularly used by the Japanese) refer to a Japanese Noh play. (Needham Research Institute, Cambridge.)

can be 'seen through', making it possible to inspect from a reflection cast onto a dark wall the written characters or patterns on the back. Somehow, mysteriously, the solid bronze becomes transparent, leading to the Chinese name for the objects, 'light-penetration mirrors'.

But surely, the reader will protest, solid bronze cannot be transparent. This is true, and there was certainly a trick to it. But it was a sufficiently good trick to baffle Western scientists for a century, and even the earliest surviving Chinese discussion of magic mirrors consists of speculation on how they might work. This occurs

1086. Even at this date, Shen Kua thought of the mirrors as coming from some vague archaic period:

There exist certain 'light-penetration mirrors' which have about twenty characters inscribed on them in an ancient style which cannot be interpreted. If such a mirror is exposed to the sunshine, although the characters are all on the back, they 'pass through' and are reflected on the wall of a house, where they can be read most distinctly.... I have three of these inscribed 'light-penetration mirrors' in my own

ancient; all of them 'let the light through'. But I do not understand why other mirrors, though extremely thin, do not 'let light through'. The ancients must indeed have had some special art.... Those who discuss the reason ... say that at the time the mirror was cast, the thinner part became cold first, while the raised part of the design on the back, being thicker, became cold later, so that the bronze formed minute wrinkles. Thus although the characters are on the back, the face has faint lines too faint to be seen with the naked eye.

Although differences of cooling rate are not the explanation, Shen Kua was correct in suggesting that the shiny, polished mirror surfaces concealed minute variations which the eye alone could not detect. Needham says of the experiments carried out by European scientists: 'Careful and extended optical experimentation demonstrated that the surfaces of "magic" mirrors reproduced the designs on the backs because of very slight inequalities of curvature, the thicker portions being very slightly flatter than the thinner ones, and even sometimes actually concave.'

The basic mirror shape, with the design on the back, was cast flat, and the convexity of the surface produced afterwards by elaborate scraping and scratching. The surface was then polished to become shiny. The stresses set up by these processes caused the thinner parts of the surface to bulge outwards and become more convex than the thicker portions. Finally, a mercury amalgam was laid over the surface; this created further stresses and preferential buckling. The result was that imperfections of the mirror surface matched the patterns on the back, although they were too minute to be seen by the eye. But when the mirror reflected bright sunlight against a wall, with the resultant magnification of the whole image, the effect was to reproduce the patterns as if they were passing through the solid bronze by way of light beams. As Sir William Bragg said when he finally discovered this in 1932: 'Only the magnifying effect of reflection makes them plain.' Needham rightly calls all of this 'the first step on the road to knowledge about the minute structure of metal surfaces.'

What makes magic mirrors so mysterious is that, although they are made of solid bronze, it is nevertheless possible to 'see through' them. Their very existence was thus a great encouragement to those Taoist philosophers and mystics in China who tended to

view normal matter as a grosser form of matter of a mundane sort, and felt that there must be other, far more rarefied forms of matter which were practically invisible. The Taoists even believed in a kind of immortality which meant that one continued to exist physically in a transparent and tenuous 'higher' state of matter. Such beliefs could have been justified and even demonstrated to the satisfaction of all onlookers by showing them a magic mirror and proving to them that under certain conditions, the most solid matter conceivable — cast bronze — could become 'transparent'.

### THE 'SIEMENS' STEEL PROCESS

FIFTH CENTURY AD

As described in the previous steel process, cast iron has a high carbon content and wrought iron has practically no carbon content, whereas steel must be somewhere in between if it is to have all the desired characteristics. About the fifth century AD, the Chinese developed the 'co-fusion' process, in which cast and wrought iron were melted together to yield the 'something in between', which was steel. This is essentially the Martin and Siemens steel process of 1863, though carried out fourteen hundred years earlier.

This process was in full swing by the sixth century, from which time we have a Chinese description of it: 'Ch'iwu Huai-Wen also made sabres of "overnight iron". The method was to bake the purest cast iron, piling it up with the soft ingots of wrought iron, until after several days and nights, it was all turned to steel.'

Another account appears in the seventh century. In the *Newly Reorganized Pharmacopoeia* of 659 AD we read: 'Steel is made when the raw cast iron and the soft wrought iron are mixed and heated together. It is for making sabres and sickles.'

And in the eleventh century, Su Sung informs us that: 'By mixing the raw and the soft (cast iron and wrought iron), a metal is obtained for making the edges and points of sabres and swords; this is called steel....

We are given precise technical details by Sung Ying-Hsing in 1637:

The method of making steel is as follows. The wrought iron is beaten into thin plates or scales as wide as a finger and rather over an

LEFT (41) A Chinese blast furnace in operation in the year 1637. On the right, a manually-operated double-acting piston bellows fans the fire. One of the central labels is to 'lumps of steel dropping out', referring to lumps of viscous medium-carbon iron which will be turned into true steel later by the 'co-fusion' process invented in the fifth century. It was essentially the 'Martin and Siemens' steel process of 1863, fifteen hundred years earlier.

inch and a half long. These are packed within wrought iron sheets and all tightly pressed down by cast iron pieces piled on top. The whole furnace is then covered over with mud (or clay) as well. Large furnace piston bellows are then set to work, and when the fire has risen to a sufficient heat, the cast iron comes to its transformation [i.e. melts] first, and dripping and soaking, penetrates into the wrought iron. When the two are united with each other, they are taken out and forged; afterwards they are again heated and hammered. This is many times repeated.

In our own time, experiments have been carried out at the steel works at Corby in England to reproduce the ancient Chinese steel-making techniques. The experiments were thoroughly successful. A very uniform steel was obtained, with the carbon from the cast iron spread evenly throughout, and a genuine blending of the cast and wrought iron. The original heating went up to 975°C, and the metal was taken out and forged with a hand hammer. It was then heated for eight hours at 900°C and came out beautifully.

It should be mentioned that another key ingredient to the Chinese success story in iron and steel technology was the invention of special bellows for blowing air (see page 46). It enabled a continuous stream to be applied, uninterrupted by the moving backwards of the piston. It would have been impossible

to achieve such success with an unstable, huffing and puffing airstream in such a high temperature steel process. Furthermore, the application of hydrodynamic power to work the piston bellows by means of a horizontal water wheel made larger bellows possible. We must not forget, therefore, that the story of iron and steel in China is at all times surrounded by stories of other, interdependent inventions and techniques.

### THE SEGMENTAL ARCH BRIDGE

SEVENTH CLAID RY AD

A conceptual breakthrough occurred when a Chinese engineer was the first to realize that an arch did not have to be a semi-circle. A bridge could be built which was based not on the traditional semi-circular arch but on what is known as a segmental arch. The way to envisage this is to imagine a gigantic circle embedded in the ground, of which only the tip shows above ground level. This tip is a segment of a circle, and the arch it forms is a segmental arch. Such an arch forms the central arch of the bridge in Plate 42 (page 78). Bridges built in this way take less material and are stronger than ones built as semi-circular arches.

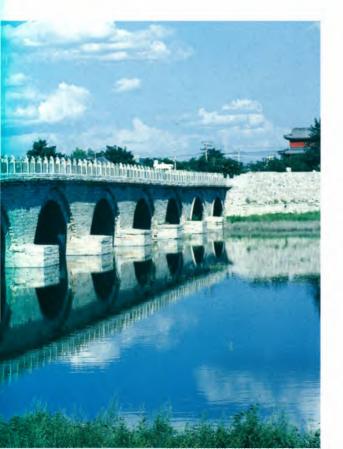

This advance took place in China in the seventh century AD. It was the concept of a genius, Li Ch'un, the founder of an entire school of constructional engineering whose influence lasted for many centuries. We are fortunate in that his first great bridge, built in

610, survives intact and is still very much in use today. Called the Great Stone Bridge, it spans the Chiao Shui river near Chao-hsien, at the foot of the Shansi Mountains on the edge of the North China Plain. It was featured on a postage stamp in 1962 and is one of the achievements of early Chinese engineers of which the modern Chinese have most knowledge, and of which they feel most proud. Many legends have attached themselves to the bridge over the centuries, and about the sixteenth century a poet spoke of it as 'looking like a moon rising above the clouds, or a long rainbow hanging on a mountain waterfall'.

It is difficult for us today to appreciate just how impressive a sight the Great Stone Bridge must have been to pre-modern eyes. For we are used to seeing pre-stressed concrete examples of segmental arch

LEFT (42) The Great Stone Bridge spanning the River Chiao Shui is the world's first segmental arch bridge, built in stone by the architect La Ch'un in the year 610 and renovated in the twentieth century. The bridge has a span of 123 feet. Not only was the great segmental arch in the centre an iunovation (semi-circular arches had existed before), but the semi-circular arch spandrels to either side were also new. They let through additional flood waters and also allowed the structure to be lighter in weight. Such arches did not reach Europe for five hundred years.

bridges everywhere, spanning all the expressways and motorways of the modern world. But in the seventh century, eyes were not so jaded, and the following inscription was carved on the Great Stone Bridge a little over a century after its construction, in 729:

This stone bridge over the Chiao River is the result of the work of the Sui engineer Li Ch'un. Its construction is indeed unusual, and no one knows on what principle he made it. But let us observe his marvellous use of stone-work. Its convexity is so smooth, and the voussoir-stones fit together so perfectly.... How lofty is the flying arch! How large is the opening, yet without piers! ... Precise indeed are the crossbondings and joints between the stones, masonry blocks delicately interlocking like mill wheels, or like the walls of wells; a hundred forms organized into one. And besides the mortar in the crevices there are slender-waisted iron clamps to bind the stones together. The four small arches inserted, on either side, break the anger of the roaring floods, and protect the bridge mightily. Such a master-work could never have been achieved if this man had not applied his genius to the building of a work which would last for centuries to come.

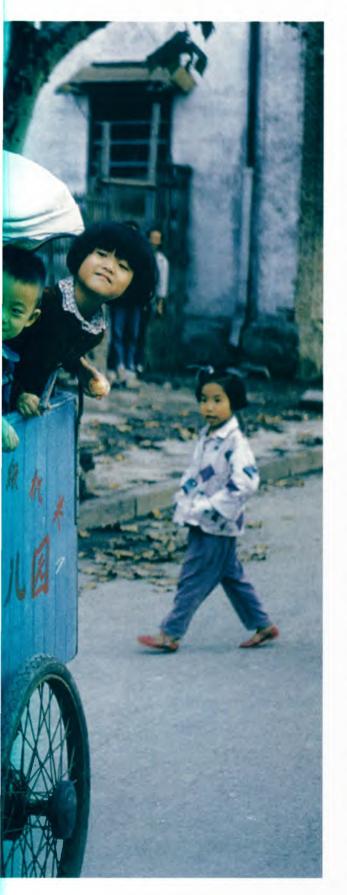

The four small whole arches, 'breaking the anger of the roaring waters', were incorporated within the structure of the main bridge. They were an innovation of great consequence in bridge-building, for they were the world's first arched spandrels. Li Ch'un found that by punching these holes in the ends of the bridge he could accomplish several things at once: flood waters could rush through them, lessening the chance that the main bridge would be swept away at its supports in a sudden flood; the total weight of the bridge could be lessened, thereby diminishing the tendency to buckle by the ends sinking down into the river banks; and vast quantities of material could be saved, which would normally have gone to make solid ends for the bridge.

The Great Stone Bridge has a span of 123 feet. The largest surviving Roman whole arch bridge, the

LEFT (43) The so-called 'Marco Polo Bridge' just west of Peking (Beijing), spanning the Yung-ting river. It is China's greatest segmental arch bridge, built in 1189 and consisting of a succession of eleven segmental arches with a total span of 700 feet.

ABOVE (44) The chain-drive, the essential mechanism of the bicycle, was invented in Chma in 976 but did not appear in Europe until 1770.

Pont St Martin near Aosta, spans 117 feet. But the average whole arch Roman bridge spanned between 60 and 80 feet, whereas whole arches in Roman aqueducts had an average span of about 20 feet. The Great Stone Bridge was five hundred years ahead of Europe in one sense and six hundred years ahead in another. For the principle of the segmental arch in bridge construction, brought to Europe about Marco Polo's time, first began to be applied in the West at the end of the thirteenth century, as may be seen in the surviving Pont St Esprit across the Rhone and the small Abbot's Bridge at Bury St Edmunds in East Anglia. But it was only in the fourteenth century that the principle became widely and daringly applied. Examples are the famous Ponte Vecchio in Florence (1345), the covered bridge at Pavia (1351), and the Castelvecchio Bridge at Verona (1345). However, one has only to look at the last-named to see that arched spandrels had not yet been introduced. These came later in the same century to Europe.

The greatest segmental arch bridge in China is the famous 'Marco Polo Bridge', often so named because Polo described it at length. Just west of Peking (Beijing), it is often visited by tourists. It crosses the Yung-ting river at the small town of Lu-kou-ch'iao, and is 700 feet in length, consisting of a series of eleven segmental arches extending one after another across the river, each with an average span of 62 feet. It was built in 1189 and is still heavily used by modern truck and bus traffic. Marco Polo thought this bridge 'the finest in the world'. He was delighted by the elaborate carved balustrade, consisting of 283 marble lion heads, all different, and he enthused about how ten mounted men could ride abreast across it without the slightest inconvenience. This bridge may be seen in Plate 43 (page 78).

### THE CHAIN-DRIVE

TENTH CENTURY AD

The chain-drive for transmission of power was invented in China by Chang Ssu-Hsün in 976 AD for use in his great mechanical clock (page 116). Ever since the first century AD, square-pallet chain pumps had existed in China (page 63). Hundreds of thousands of them were to be found all over the Chinese countryside by the tenth century, and the time of Chang Ssu-Hsün. When he came to the problem of transmitting power in his clock, Chang must have

been influenced by the common sight of the sprocketed chain of the familiar chain pumps. Though those chains did not transmit power, Chang evidently saw the possibilities of doing so with a similar design. And thus it was that he incorporated this important invention in his clock.

When, in 1090, Chang's more famous successor, the inventor Su Sung, built his enormous astronomical clock tower (see page 117), he tried at first to use a main vertical transmission-shaft. But this did not work. So he also adopted the chain-drive, which he called a 'celestial ladder'. We are fortunate that we actually have a drawing of this chain-drive made by Su Sung himself, and published in 1090 in his own book *New Design for an Astronomical Clock*. It may be seen in Plate 45 (above). Obviously, it is the oldest illustration of an endless chain-drive for power-transmission in the world. A shorter and tighter chain-drive was fitted to the clock as a further improvement, when it was discovered that the key to mechanical

efficiency was to eliminate slack wherever possible in all mechanical connections.

Although we have little detail concerning Chang's earlier chain-drive of 976, we have some for that of Su Sung in 1090. The chain can be seen to have been double-linked. The chain-drive coupled the main driving-shaft of the clock apparatus with a series of three small pinions in a little gear-box, which operated the turning of the armillary sphere (an astronomical part of the clock). Su Sung himself described the chain-drive in his book by saying:

The 'celestial ladder' is 19.5 feet long – an iron chain with its links joined together to form an endless circuit, hanging down from an upper chain wheel ... and passing round a lower chain wheel on the driving-shaft.

In the ancient Western world, loose chains and pentagonal sprocket-wheels were designed, though it is doubtful if they were built, by Philon of Byzantium about 200 BC. But no transmission of power was envisaged, and the intended use

was to provide repeat-loading of a catapult. Even if this machine had been built, it would not have been a proper chain-drive.

The first genuine European chaindrive was made by Jacques de Vaucanson in 1770 for silk reeling and throwing mills. In 1869 J.F. Tretz used the chain-drive to make bicycles. Since bicycles are now the leading form of transport in China, it is ironical that only a tiny handful of the Chinese who use them have any idea that the bicycle chain-drive is a native Chinese invention eight hundred years in advance of a Western equivalent, and nine hundred years in advance of its application by a European for the bicycle.

# UNDERWATER SALVAGE OPERATIONS

ELEVENTH CENTURY AD

In the eleventh century AD, at the instigation of a monk named Huai-Ping, the Chinese pioneered a technique of recovering heavy objects from a river or sea bed.

Between 1064 and 1067, the noted pontoon bridge at P'u-Chin near P'uchow over the great

Yellow River was destroyed by a sudden flood. This bridge, which had been constructed 350 years earlier, was a major crossing of the river. It consisted of floating boats securely linked together by a great wrought iron chain. The ends of the chain were attached to eight enormous cast iron figures in the shape of recumbent oxen set in the sandy beaches on the two banks.

When the flood washed away the bridge, the iron oxen were pulled into the river and sank deep under water. The dismayed local officials issued a public proclamation requesting ideas as to how they could be recovered, and it was to this plea that Huai-Ping responded.

On his instructions, workers filled two large boats with earth, and divers attached cables from them to the oxen in the river bed. Then earth was gradually removed from the boats, which caused them to float higher and higher in the water. To everyone's delight, the buoyancy thus created lifted the oxen from the river bed. They were then dragged into shallower

water simply by sailing the boats towards the shore. From there, they were easily recovered.

This appears to be the first time in history that buoyancy techniques were used for an underwater salvage operation. These techniques are still employed today. When the giant ocean liner *Andrea Doria* sank in the Atlantic in the 1950s, the operation used to salvage the hulk involved attaching the ship – 225 feet below the surface – to ore ships full of water and then progressively emptying them, repeating the process as often as required: the very principle propounded by Huai-Ping nine hundred years earlier.

BELOW (46) An attempt at underwater salvage in the year 219 BC, shown in a bas-relief of the period. Nine bronze tripods had been lost in the River Ssu in 333 BC, and in 219 BC the emperor sent an expedition to recover them, but it was unsuccessful. However, by the eleventh century AD, the Chinese had developed sophisticated underwater salvage operations which were up to twentieth-century standards.

# LIVINICATRIAL

### LACQUER: THE FIRST PLASTIC

THIRTEENTH CENTURY BC

Lacquer was in use by at least the thirteenth century BC in China. Queen Fu Hao of that date was buried in a lacquered coffin, discovered when her intact tomb was excavated in 1976 at Anyang. Needham has said of lacquer: 'Lacquer may be said to have been the most ancient industrial plastic known to man.' It has been in use for well over three thousand years.

Lacquer is obtained rather like rubber, by tapping the sap of tree trunks. The lacquer tree (*Rhus vernicifera*, recently renamed *verniciflua* by botanists) is indigenous to China but not to Europe. It is particularly common in central China, growing at altitudes between 3000 and 7500 feet. The trees are tapped in summer and left to recover over a period of five to seven years, though in some cases they are cut down after tapping, and an inferior lacquer is obtained from their branches. The largest amount of lacquer a tree can produce is about 50 grams.

Lacquer is a plastic varnish which has remarkable powers of preservation, strength and durability. Strong acids and alkalis cannot damage it; it cannot be affected by heat less than 400°–500°F; it cannot be damaged by water or other liquids; it is insoluble to most solvents; and it is resistant to bacterial attack. Also, as an electrical insulator it is almost as good as mica. Its discovery was thus a major event. It is one of the toughest and most remarkable vegetable substances in the world, and is a natural plastic. The first artificial plastic to be discovered was celluloid, by John Wesley Hyatt, in 1869. But the modern plastics industry did not really commence until 1907 with the discovery of bakelite. Today many artificial lacquers are made, and in the plastics industry the word 'lacquer' is loosely applied to countless synthetic substances which have no connection with the lacquer tree. When a synthetic lacquer is pigmented, it is called an 'enamel'. These lacquers are therefore in every Western kitchen today.

But true lacquer was used for kitchen utensils thousands of years ago in China. Wood, bamboo or cloth utensils coated with many layers of thin lacquer formed the standard dinner service for rich Chinese in place of bronze vessels. They were able to withstand the heat of cooking and serving of food as well as metal. Chinese emperors gave lacquered articles to their officials as recognition of their services, and the monetary value of lacquerware actually exceeded that of bronzes.

Lacquer was used in China for furniture, screens, pillows and boxes of all sorts. It was worn as bonnets and shoes. Weapon accessories, such as sword scabbards, bows and shields were made of it. Lacquers were often inlaid with gold and silver or tortoiseshell. The fluidity of the lacquered surface when applied made possible a form of Chinese decoration which was as free and spontaneous as could be imagined, and this had a major impact on ancient Chinese art.

Lacquer came in many different grades, the best apparently being obtained from between the inner and outer barks of trees aged between 14 and 15 years. When lacquering an article, it is usual to commence with coats of inferior lacquers and save the best grade for the final coat. Each thin coat was applied and allowed to dry completely before the application of the next coat. In the best quality later carved work, over a hundred coats of lacquer were applied to obtain the necessary

OPPOSITE (47) A red lacquer throne of the Ch'ing Dynasty, dating from the period 1736-96. (Victoria and Albert Museum, London.)

depth for carving. Various pigments can be added to give colour, the traditional basic colours being black, red, brown, yellow, gold and green. A particularly intriguing colour was the 'pear-ground lacquer' made with gold dust and gamboge gum resin.

The lacquer industry in ancient China was highly organized, in the traditional Chinese bureaucratic way. There were both private and state lacquer manufacturing centres. There is a lacquered wood wine cup in the Musée Guimet, Paris, which can be dated precisely to the year 4 AD by an extraordinary inscription which, besides giving the date of manufacture, lists seven artisans involved in making the cup and five other officials of the company. This offers a fair idea of the Chinese approach to manufacturing as long as two thousand years ago. Twelve people to produce a single cup, nearly half of them functionaries who perhaps never even saw it! But on the other hand, it indicates also the use of something very like the modern industrial production-line.

As early as the second century BC, the Chinese had made important chemical discoveries about

lacquer. They found a way to keep it from going hard by evaporation. What they did sounds like an old wives' tale – they threw crabs into lacquer to keep it liquid! The *Book of Master Huai Nau*, of 120 BC, however, says that crabs spoil lacquer so that it will not dry and cannot be used. Many subsequent authors mentioned this apparently ridiculous tradition. Li Shih in the twelfth century wrote that 'after coming in contact with crabs, lacquer will not concrete'.

Crustacean tissue does in fact contain powerful chemicals which inhibit certain enzymes, including the one which makes lacquer solidify! Needham comments on this bizarre business as follows:

What part, then, were the crab tissues playing? There can be no doubt that the ancient Chinese, before the 2nd century BC, had accidentally discovered a powerful laccase inhibitor. By preventing the action of the enzyme the darkening and polymerization were also prevented. So great an interference with the course of nature, analogous to the arrest of a spontaneously occurring rigidification

and ageing process, must have seemed highly significant to the alchemists, preoccupied as they were by the preservation of supple youth and the postponement or elimination of ankylosis and death. Moreover this action of crustacean tissues is not unique, for other researches have shown that they contain a powerful though somewhat enigmatic inhibitor for D-amino-acid oxidase.

Not only did the perpetual liquefaction of lacquer pose a model for immortality, in this proto-industrial biochemistry, but lacquer accompanied a Chinese from cradle to grave – he would be fed as a baby from lacquer vessels with lacquer ladles, and in death he would be buried in a beautifully ornamented lacquer coffin.

### STRONG BEER (SAKE)

ELEVENTH CUNTURY BU

Many Westerners are familiar with Japanese *sake*, but few will know that it represents a type of alcoholic drink which has only ever been made in China and Japan (where it was introduced from China). *Sake* is neither a wine nor a spirit. Some *sake* made today has been strengthened with spirit, but *sake* itself is a type of alcohol known in China as *chin*, of which a very rough translation is 'strong beer'.

Ordinary beer, with an alcohol content reaching perhaps 4 or 5 per cent, has been made throughout

LEFT (49) As a member of a production line making lacquer objects, this craftsman is depicted cutting decorative incisions in the lacquer. An inscription on a lacquer cup of 4 AD reads: 'Priming by Yi; lacquering by Li; outer coat by Tang; gilding of the handles by Ku; painting by Ting; inscribed by Peng; cleaning and polishing by Chung.' This worker, in a painting of the late eighteenth century, represents yet another stage in the process.

the world for thousands of years. It was known to the Egyptians and Babylonians, and mention of it as an offering to the spirits in sacrifices occurs in early bone inscriptions in China dated about 1500 BC. There were many different kinds of this ordinary beer, with varying ingredients, from assorted regions.

By 1000 BC at the latest, and perhaps centuries earlier, the fermentation process was well established in China for the making of *chin*. It was at least three times as strong as ordinary beers. Whereas in the West no beverage attained an alcohol content of more than about 11 per cent (achieved by some wines) before distilled alcohol appeared, this 'strong beer' in China is thought to have had a substantially higher alcohol content. Poems surviving from 800 BC or earlier describe people getting tipsy on this heady brew.

The strong beer fermentation process involved an entirely new concept in fermentation of grain. The major problem with ordinary beer is that the starch in grain cannot be fermented. Thousands of years ago, it was found that sprouting grain contains a substance (the enzyme now known as amylase) which degrades the starch of grain into sugars which can then be fermented. This was the basis of ancient beer around the world; sprouting grain would be dried as malt, which would 'digest' the starch of the normal grain for beer.

Although the Chinese made this sort of beer like everyone else, they found that a far better technique was to make something called *chii*. This consisted of ground, partially cooked wheat (or occasionally millet) grains which had been allowed to go mouldy. These moulds produce the starch-digestive enzyme amylase more efficiently than does sprouting grain. *Chii* therefore was a mixture of moulds plus yeast. The Chinese would mix it with cooked grain in water, which resulted in beer. The amylase broke the starch down into sugar and the yeast fermented this into alcohol.

ABOVE (50) A late-eighteenth-century painting of a street seller of the Chinese drink known in Japan as *sake*. The drink is neither a wine nor a spirit, but is actually a 'strong beer' of which there is no Western equivalent. (Victoria and Albert Museum, London.)

It was also found that the alcohol content could be raised by continually adding more and more cooked grain in water to the brew as the fermentation proceeded. They call this 'killing' the grain. This 'topping-up' process eventually reached a peak above which it would not go, but it led to a very strong drink indeed. Apart from its spread to Japan centuries ago, 'strong beer' has never been adopted by other cultures, and indeed there remains no direct translation of its name into any Western language. This is one Chinese invention which has yet to be appreciated by the world at large.

# PETROLEUM AND NATURAL GAS AS FUEL

EOURTH CENTURY BC

Petroleum and natural gas were used as fuel in China many centuries before the West and it is probably a conservative estimate to say that the Chinese were burning natural gas for fuel and light by the fourth century BC. We know that this occurred before the Han Chinese overmastered the local tribes in the southern province of Szechuan, starting in the third century BC. The deep boreholes drilled for brine also yielded natural gas from time to time. These methane gas deposits tended to occur under the brine, but many boreholes, including those intended for brine, yielded only natural gas and were known to the

Chinese as 'fire wells'. These boreholes were being drilled systematically for brine by at least the first century BC, so that deep supplies of natural gas were tapped from that date by boreholes going down at least several hundred feet. And the systematic search for natural gas itself by deep drilling is recorded in the second century AD.

Ch'ang Ch'ü in 347 recorded in his book Records of the Country South of Mount Hua:

At the place where the river from Pu-p'u joins the Huo-ching River, there are fire wells; at night the glow is reflected all over the sky. The inhabitants wanted to have fire, and used to ignite the gas outlets with brands from household hearths; after a short time there would be a noise like the rumbling of thunder and the flames would shoot out so brilliantly as to light up the country for several dozen li around [several miles at least]. Moreover they use bamboo tubes to 'contain the light', conserving it so that it can be made to travel from one place to another, as much as a day's journey away from the well without its being extinguished. When it has burnt no ash is left, and it blazes brilliantly.

The bamboo tubes here probably refer to pipelines, though we shall see that portable containers for the gas were later used. Bamboo pipelines did indeed

RIGHT (51) A photograph taken by Cecil Beaton in the province of Szechuan. On the left is a well-head with several derricks in the background. In the foreground are the traditional bamboo pipes which were used to lead natural gas many miles over hill and dale to nearby towns, where it would be burnt for heat and light.

RIGHT (52) A previously unpublished photograph taken in about 1900 by Ernst Boerschmann, showing the drilling derricks of the Szechuan natural gas fields.

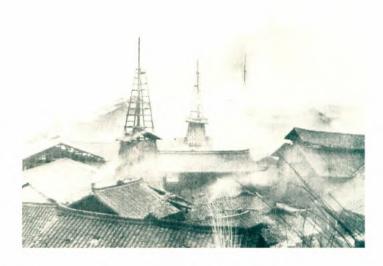

carry both brine and natural gas for many miles, sometimes passing under roads and sometimes going overhead on trestles. If the brine needed lifting again to greater heights in order to flow downwards by gravity, pumps were employed. But this was not necessary for natural gas, which rose naturally.

The ignition and use of the natural gas for light and fuel posed problems which were successfully overcome by the ancient Chinese. The natural gas which comes from shallow boreholes is not very strong,

and if piped directly to burners, can be lit safely. But the kind of pungent, powerful natural gas which the Chinese obtained from the majority of their boreholes, from depths below 2000 feet, had to be mixed with air before it could be safely burnt. There must have been many catastrophic explosions before the principles involved were learned.

Old texts describe in some detail the complicated arrangements which were eventually adopted to control the burning of natural gas. The gas from the 'fire wells' was fed first into a large wooden chamber about 10 feet below ground level over the mouth of the borehole. It was basically a cone-shaped barrel into which an underground pipe also conveyed air. The chamber therefore acted as a great carburettor, feeding into banks of pipes which led to other smaller conical chambers which rested on the surface of the earth. These too took in air, with a variety of entry pipes which could be opened or closed, so that a finetuning of the 'engine' was possible by a continuous manipulation of the fuel/air mixture. If the pressure of the mixture were to flag, dangerous flash-backs and explosions could occur, so the main chamber would be opened up further. But fires could result if the mixture were too rich, so surplus gas was allowed to escape through what was called a 'sky thrusting pipe' exhaust system.

Although uncontrolled emissions of natural gas, when ignited, could either flame up 100 feet in the air, or even explode, the wells with 'carburettors' had

their gas piped along tubes to the various outlets where flames 1½ feet high were commonly produced. These would be used to heat evaporation pans of brine. The cast iron pans were gigantic and weighed as much as 1000 pounds, though there were outlying pans which were smaller. The brine was gently warmed in the smaller pans, and then transferred to the great pans for fierce boiling. Natural gas from very shallow wells could easily heat between ten and forty pans. But from the more common deep wells of about 3000 feet depth, the gas commonly serviced 600 to 700 burners, and one case at Fu-ch'ang is recorded where as many as 5100 evaporation pans were heated by a single 'fire well', though this figure must include small as well as large pans.

Flames smaller than 1½ feet high were used for other purposes, such as providing lights in certain Szechuan towns. These early gas lamps anticipated Victorian England by many centuries. The gas was also available for heating in these towns, though details of how it was employed are lacking. It seems doubtful that proper gas stoves existed, and it is more likely that the heating applications were generally for cooking and boiling uses. More research is necessary in the old gazetteers of Szechuan in order to try to find further information about the uses to which natural gas and petroleum were put there over the millennia. The thousands of regional Chinese gazetteers, which go back many centuries, have never been properly studied, and priceless information

relating to Chinese science and technology has been found in those few which have been examined.

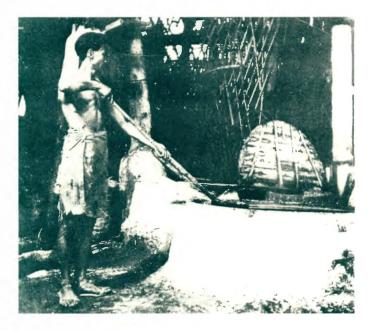

It is one such gazetteer, dating from before the tenth century, and surviving only in quotations in a later work, which tells us how the Szechuanese anticipated modern portable butane gas cylinders for carrying supplies of natural gas:

Lin-ch'iung has a fire well which is over 600 feet deep and which burns brightly at the opening. People use tubes to carry it around, and they can go over a hundred *li* [dozens of miles] and still be able to light it.

Thus, a man could travel for a couple of days and then open up his gas cylinder, probably through a tap, and cook himself a meal. Other portable heat sources included petroleum products, which often went under the name of 'stone lacquer' because they looked like lacquer but seeped from the stones. A book of 980 records:

Some fire wells produce a liquid too. The people of the commandery use bamboo tubes to carry it to light their way in the same manner as ordinary people carry torches. This is because the liquid is inflammable.

Another book by Yang Shen in the sixteenth century recorded of the 'fire wells' at K'ang-ting and Chien-wei:

The streams produce oil which when heated bursts into flame. People take it and use it in lamps like candles. This oil is just an accumulation of solar essence. It is nothing strange.

The domestic uses of petroleum products seem to have been confined to modest applications such as oil lamps and oil-fired torches, but they were used on a large scale for breaking up rocks by fire. Since burning oil could burn in water, boulders in harbours were sometimes broken apart by having burning oil poured over them.

The bamboo tube 'butane cylinders' have apparently been seen in use in the hinterland of China by modern scholars, though no photograph appears to exist of one in operation. Leather bags were also employed. A seventeenth- or eighteenth-century account survives in one of the Szechuan gazetteers, entitled *Historical Geography of Fu-shun in Szechuan*:

There is a fire well 90 *li* west of the prefectural seat of Fu-shun which is 40 to 50 feet deep and has an opening 5 or 6 inches in diameter. Gas rises up from it. Bamboo tubes with their partitions removed lead it off from the well and when fire is applied the gas ignites. The flames may be small or they may leap up several feet into the air making a noise like thunder as they burn; the gas is led through underground conduits to heat

the brine, never ceasing day and night. When not wanted for use, it is doused with water and extinguished. Furthermore, bamboo tubes which have been bored through are joined together to lead the gas away. It can be used as a

LEFT (53) A photograph taken by Cecil Beaton during the Second World War, showing a workman at the Ts'iuch'ing Salt Wells in Szechuan Province. He is stirring brine in a vat which is being heated by the jet of a natural gas flame, in the manner practised since the fourth century BC in China. Natural gas is found below brine deposits in sufficiently deep wells. Using their traditional drilling techniques, the Chinese could reach depths of 4800 feet.

substitute for firewood and torches. Travellers going to a distance carry the gas with them in leather bags. After travelling even as far as several thousand *li*, a hole is punctured, touched with fire, and light and heat come instantaneously.

But because these phenomena were rather regional in nature, the Chinese of other regions did not necessarily have much familiarity with them. About 1600, Sung Ying-Hsing wrote:

The 'fire wells' of Western Szechuan are a highly amazing phenomenon; there is cold water in them but not the slightest evidence of the essence of fire. Yet men take long bamboo stems and split them, then put them together again so as to form a pipe, wrapping it securely with varnished cloth; this tube they insert into the well ... it will be seen that hot dry flames are bursting forth from the pipe.... Yet if the bamboos are opened and examined, no sign of charring or burning can be seen. To use the spirit of fire without seeing the form of fire – this is indeed one of the strangest things in the world.

#### PAPER

SECOND CENTURY BO

Although the word 'paper' is derived from the word 'papyrus', paper and papyrus have nothing whatever to do with one another. Papyrus, which existed in Egypt as early as the third millennium BC, is made from the inner bark of the papyrus plant (*Cyperus papyrus*). Apart from the fact that it gives a sheet on which one can write, it is completely and totally different from paper. The Chinese invented paper, by the second century BC at the latest.

Paper in the modern world is mostly made of wood pulp. But, just to confuse the issue even more, paper in ancient times was never made of wood pulp. So, what then is paper?

Paper is the sheet of sediment which results from the settling of a layer of disintegrated fibres from a watery solution onto a flat mould, the water being drained away, and the deposited layer removed and dried. The fibres can be of any material whatever, though plant fibres are by far the most commonly used ones, and as remarked above, fibres from trees are the mainstay of the paper industries today. The earliest European paper was not made of wood pulp, but of disintegrated and pounded rags of linen. Anyone who owns or has handled a book printed in the seventeenth century in Europe will be aware of how durable and springy the paper is; this paper is made of linen, and it will still be youthful and fresh when most of the books printed in the twentieth century have disintegrated to dust.

The oldest surviving piece of paper in the world was discovered by archeologists in 1957 in a tomb near Sian in Shensi Province, China. It is about 10 cm square and can be dated precisely between the years 140 and 87 BC. This paper and similar bits of paper surviving from the next century are thick, coarse, and uneven in their texture. They are all made of pounded and disintegrated hemp fibres. From the drying marks on them, it is evident that they were dried primitively on mats woven as pieces of fabric, not on what we know as paper moulds. In these early days, the water just drained slowly through the underlying mat of fabric, leaving the paper layer on top. This was then peeled off and dried thoroughly. But so thick and coarse was the result that it could not have been very satisfactory for writing.

However, paper does not appear to have been used as a medium for writing until a considerable time after its invention. The oldest surviving piece of paper in the world with writing on it was discovered under the ruins of an ancient watchtower in Tsakhortei near Chü-yen in 1942. The watchtower was abandoned by Chinese troops during the rebellion of the Hsich'iang tribe, and the paper can thus be dated to 110 AD. It contains about two dozen readable characters.

It is probable that paper was in use for a century or more in China before its possibilities as a medium for writing were noticed. Its earliest uses were in connection with clothing, wrapping, lacquerware and personal hygiene. A text of 93 BC records an imperial guard recommending to a prince that he cover his nose with a piece of paper — the first Kleenex! A record of a murder case from 12 BC notes that the poison used had been wrapped in red paper. By the time of the Emperor Kuang–Wu (reigned 25–26 AD), an official of the imperial secretariat was already responsible for 'the seals and cords of office, and for paper, brush, and ink.'

The use of paper for clothing may at first seem strange; we think of paper as being thin today, and hardly the proper material to keep out the cold. But the use of paper as protective clothing against the cold was practised by the Chinese from the second century BC onwards. We are not certain when the Chinese in the south began making paper of the bark of the paper-mulberry tree (*Bronsonetia papyrifera*), but the pounded bark of this remarkable tree was found to be serviceable for clothing from an early date. And it would seem that not long after paper proper was invented, the disintegrated fibres of paper-mulberry bark were employed, as well as the more common hemp, to make real paper.

However, the earliest uses of paper were derived from the simple pounded bark of this tree. We know that in the sixth century BC, a disciple of Confucius named Yüan Hsien from the State of Lu wore a hat made from paper-mulberry bark. The historian Ssuma Ch'ien records that in the second century BC, huge quantities of this substance were in commercial circulation. A paper hat, a paper belt, and a paper shoe dating from 418 AD were discovered in an excavation at Turfan, and reported in 1980.

But surely articles of clothing made from paper were too flimsy? Perhaps the inferior paper of today, made from wood pulp, would be. But the paper of those days, made from much stronger and tougher fibres, was not. So tough was paper then that it was

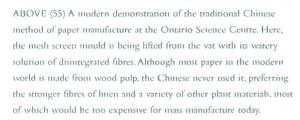

frequently used as a shoe liner. And paper clothing was so very warm and impenetrable by cold winds that people complained that it allowed no circulation of air round the body and was too hot to wear! Beds in winter were kept warm with paper curtains, and thin curtains, also of paper, were used as mosquito nets.

The poet Lu Yu wrote a letter to the philosopher Chu Hsi about the year 1200, thanking him for the gift of a paper blanket. The letter survives, and we are able to enjoy the amusement of reading Lu Yu's rapturous account: 'I passed the day of snow by covering me with a paper blanket. It is whiter than fox fur and softer than cotton.'

Not only was paper used for clothing, it was used for military armour! In the ninth century a provincial governor named Hsü Shang is recorded as keeping an army of a thousand soldiers ready at all times clothed in pleated paper armour which could not be pierced by strong arrows. Paper armour became common on land and at sea. When two pirate ships surrendered in an amnesty in the twelfth century, 110 suits of paper armour were handed over by them. And in the twelfth century, 'Chen Te-Hsiu is recorded as saying that he had sufficient weapons at his fort for defence, but of his hundred sets of iron armour, he had kept half of

ABOVE (56) A later stage of the modern demonstration at the Ontario Science Centre. Here, the layer of sediment accumulated on the mould from the vat has dried and is being delicately peeled off – a sheet of paper. Paper (which is completely different from papyrus) was invented in China by the second century BC, but did not reach Europe until a thousand years later. Its secret remained undiscovered for another four hundred years after that, and paper was not made in Europe until the twelfth century.

them and traded in the other fifty for sets of the better paper armour. Even bullets from guns were said to be unable to pierce good paper armour, as we read in this account in 1629 by Mao Yüan-I:

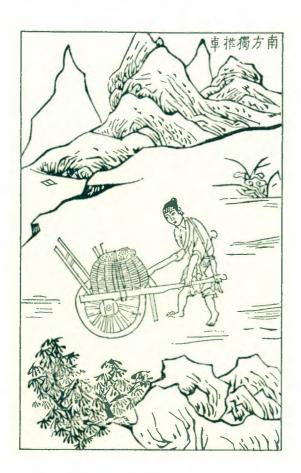

Armour is the basic equipment of soldiers, with which they are able to endure without suffering defeat before sharp weapons. The terrain in the south is dangerous and low, and where foot soldiers are generally employed they cannot take heavy loads on their backs when travelling swiftly. If the ground is wet or there is rain, iron armour easily rusts and becomes useless. Japanese pirates and local bandits frequently employ guns and firearms, and even though armour made of rattan or of horn may be used, the bullets can nevertheless pierce it. Moreover, it is heavy and cannot be worn for too long. The best choice for foot soldiers is paper armour, mixed with a variety of silk and cloth. If both paper and cloth are thin, even arrows can pierce them, not to say bullets; the armour should, therefore, be lined with cotton, one inch thick, fully pleated, at knee length. It would be inconvenient to use

in muddy fields if too long and cannot cover the body if too short. Heavy armour can only be used on ships, since there soldiers do not walk on muddy fields. But since the enemy can reach the object with bullets, it could not be defended without the use of heavy armour.

The Chinese also invented wallpaper, apparently as a result of hanging up large printed paper sheets which it was found more convenient to glue to the walls. Wallpaper was brought to Europe from China in the fifteenth century by French missionaries.

As for the sanitary uses of paper, there are some staggering statistics for this from China. In 1393, the Bureau of Imperial Supplies manufactured 720,000 sheets of toilet paper, measuring 2 feet by 3 feet each, for the use of the imperial court for one year. In addition, 15,000 special sheets, 3 inches square, 'thick but soft, and perfumed' were prepared for the exclusive use of the imperial family for the same year. Toilet paper was generally made from rice straw fibres, which were cheap and easy to process. Untold millions of sheets of toilet paper were in use in the Middle Ages. In and around the year 1900 in the province of Chekiang alone, the annual production

of toilet paper amounted to ten million packages of between 1000 and 10,000 sheets each. This means that Chekiang was producing between ten and one hundred billion sheets per year at a time when barely any at all was presumably being used in the West. If we multiply the Chekiang statistics to take in the whole of China, it means that many thousands of billions of sheets of toilet paper were being used there a century ago. How far back did the use of toilet paper go in China? We can trace it in texts from as far back as the sixth century, when the scholar official Yen Chih-T'ui wrote in 589: 'Paper on which there are quotations or commentaries from the Five Classics or the names of sages, I dare not use for toilet purposes.' And an Arab of 851 wrote: 'They [the Chinese] are not careful about cleanliness, and they do not wash themselves with water when they have done their necessities; but they only wipe themselves with paper.'

ABOVE (57) A wheelbarrow for carrying particularly heavy loads, as used in southern China in the seventeenth century, and still in use today by farmers and workmen. This engraving was published in 1637 in the book. The Creations of Nature and Man (Tien-kning k'ai-uni).

The other uses of paper in China were so many that it would take too long to enumerate them in this volume. Obviously paper was important for the making of kites, another Chinese invention (page 188) and the Chinese were also the world's leading paper-folders, as well as paper-cutters for decorative designs. Some ancient paper flowers survive to this day, and the art of origami (fancy paper-folding), which originated in China, is now popular around the world. Paper umbrellas and paper money both originated in China and are discussed elsewhere (pages 108 and 131). The large number of substances whose fibres were used for Chinese paper-making make a study in themselves, and include bamboo, straw of rice and wheat, sandalwood, hibiscus, seaweed, floss silk from silk cocoons, rattan, jute, flax, and ramie. Chronologically, hemp was the main material in earliest times, followed by paper-mulberry fibres, then rattan, then bamboo, and later straw. All sorts of fancy, perfumed, glossy and other special papers were prepared in China, some of which probably excel any which have ever been produced in the West.

Paper reached India in the seventh century and West Asia in the eighth century. For five centuries the Arabs jealously guarded the secret of paper-making and would not reveal it to the Europeans, but sold them paper instead - at great profit. The Arabs had learned the techniques of paper manufacture from some Chinese prisoners of war captured after a battle at Samarkand. Europe obtained its first paper through the Arabs at around the end of the eighth century. However, the next signs of paper being used in Europe date no earlier than the eleventh century, and paper seems to have been slow to replace papyrus in the West. The first manufacture of paper in Europe dates from the twelfth century, and it was not until the thirteenth century that an Italian paper industry could be said to be in full swing. This is fifteen hundred years after its invention in China.

#### THE WHEELBARROW

FIRST CENTURY BO

It may seem difficult to believe, but wheelbarrows did not exist in Europe before the eleventh or twelfth century. The earliest known Western illustration of a wheelbarrow is in a window at Chartres Cathedral, dated about 1220. Considering that the use of wheelbarrows could cut the number of labourers required for any building project by half, the lack of them before this must have been as appalling as the welcome of them must have been ecstatic.

The wheelbarrow was apparently invented in south-western China in the first century BC by a semi-legendary personage called Ko Yu. We say 'apparently' because, first, it may have existed before that and, secondly, Ko Yu may either have been an actual individual of that name, or otherwise may be a sort of artisan's deity for wheelbarrow-makers. In both Kan Pao's Reports on Spiritual Manifestations (348 AD) and Liu Hsiang's Lives of Famous

Immortals (compiled between the first

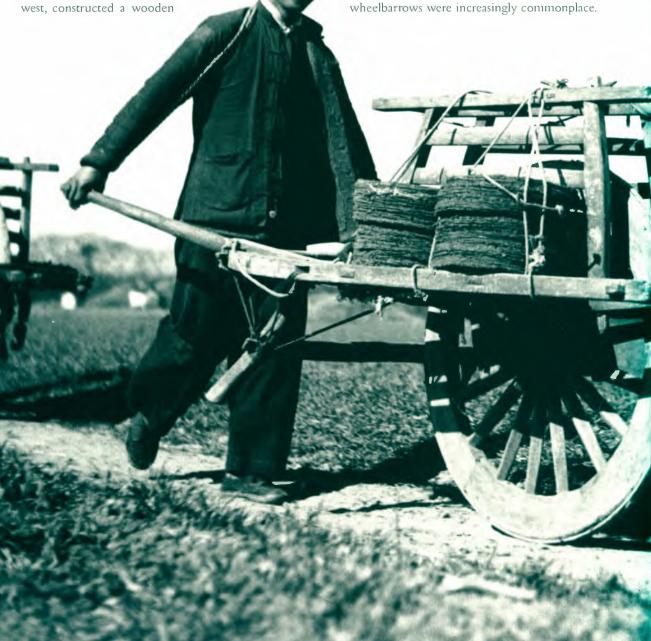

century BC and fourth century AD) we are told that Ko Yu, a noted Taoist from

Szechuan Province in the south-

goat or sheep and rode away into the mountains on it. This was a conventional early way of speaking of wheelbarrows, for in the third century AD, wheelbarrows constructed by Chuko Liang were called a 'wooden ox' and a 'gliding horse'. The former was said to be pulled by shafts in front, while the latter was said to be pushed by shafts behind.

The oldest surviving picture of a wheelbarrow dates from about 100 AD. It is a frieze relief from a tomb-shrine excavated near Hsüchow, which very clearly shows a wheelbarrow with a man sitting on it.

In another contemporary illustration, this time from a tomb of about 118 AD at Ch'engtu in Szechuan, a man is seen pushing a wheelbarrow. There are several other illustrations from this period, the Han Dynasty, indicating that wheelbarrows were increasingly commonplace.

The earliest descriptions of the construction of wheelbarrows are couched in coy and obscure language. For the first few centuries, wheelbarrows were of great military importance, and specifics of their construction were closely guarded secrets. Various sorts were produced which could carry hundreds of pounds each. Some carried men on seats, and others carried supplies. Huge numbers of them were used to supply armies fighting in difficult, hilly terrain, in which China abounds. Many battles could never have been fought and won without wheelbarrow supply brigades. Another use of wheelbarrows was to form protective movable barriers against cavalry charges, which could be arranged in any shape at a moment's notice. The ingenuity of the Chinese at exploiting the wheelbarrow was limitless, and they were even

OPPOSITE (58) Barbed wire being transported by a traditional Chinese wheelbarrow near Shanghai in 1938. The Chinese invented the wheelbarrow in the first century BC, but it did not reach Europe before the twelfth or thirteenth century AD, and many of the best wheelbarrow designs have never been adopted in the West. This type, with the large central wheel, can be pulled from the front as well as pushed from behind, and can carry more than 2 tons.

given sails, with which they could achieve speeds over land or ice of 40 miles per hour (see account on page 216).

Scenes from medieval China showing wheelbarrows abound. We are fortunate that a great painting by Chang Tse-Tuan of the city K'aifeng (then the capital in the year 1125 survives, in which various types of wheelbarrow may be seen. An empty one stands before a draper's shop, while a loaded one passes a dyeing establishment. Another is seen being loaded with sack-like objects outside the best hotel, while beside it in the street passes one so heavily laden that a mule pulls it, with one man pushing and another man pulling. Wheelbarrows were thus ubiquitous features of Chinese life - and still by this time they had not yet reached Europe.

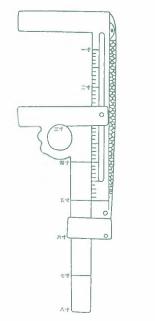

A large variety of designs existed, some with wheels in the dead centre, with the weight resting entirely on the axle, and others with wheels forward as they are today in the West. Some had tiny wheels, some had huge ones. Additional small wheels were sometimes fitted in front to ease the passage over potholes and other obstacles. Practically any shape and size of wheelbarrow existed - and still exists - in China. Many of these designs have still not passed beyond the confines of China and made their way West, despite the fact that, for particular uses, many of them are far superior to the kind Westerners generally use. One can honestly say that the wheelbarrow in all its forms is still an invention which the West has yet to discover!

## SLIDING CALLIPERS

FIRST CENTURY BO

A measuring tool very much like the modern adjustable wrench (spanner) was used in ancient China at the time of Christ. Plate 59 (page 98) shows a diagram of one.

The tool, which is made of bronze, is an adjustable sliding calliper gauge with slot and pin. The only difference between it and a modern adjustable wrench is that it does not have the small revolving worm (screw). The side which was used for measurement is decimally graduated in 6 inches and in tenths of an inch. On the other side there is an ancient inscription which, translated, reads: 'Made on a kuei-yu day at new moon of the first month of the first year of the Shih-Chien-Kuo reign-period.'

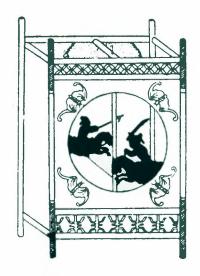

ABOVE (59) These sliding callipers are an adjustable spanner, without the worm. Unknown in Europe before Leonardo da Vinci sketched a set, they first came to be used in France in 1631, but the Chinese invented them in the first century BC. This illustration, published in China in 1925, depicts a surviving example of the measuring tool in bronze, with slot and pin for the sliding adjustment outside the calliper gauge, which dates from 9 AD, and bears an inscription on the right side which says it was 'Made on a kuei-yu day at new moon of the first month of the first year of the Shih-Chien-Kuo reign-period'. The left side of the tool is graduated in 6 inches and tenths of an inch.

This dates the implement to the first year of the reign of the Emperor Wang Mang, or 9 AD. This is the most impressive measuring instrument surviving

from any ancient culture. These sliding callipers graduated in inches and tenths of inches must have been developed by the preceding century, the first century BC.

In Europe, sliding-scale callipers were introduced by Pierre Vernier in 1631, and the screw micrometer by William Gascoigne in 1638 for use

RIGHT (60) The magic lantern, also known as the 'pacing horse lantern', had been invented by the second century AD in China. This traditional example shows horsemen which move round a central light. Magic lanterns seem to have reached Europe in the seventeenth century.

in astronomy. The date of the earliest European calliper gauge is not known for certain before this, though the first such idea seems to have occurred in sketches made by Leonardo da Vinci over a century earlier. For the full sliding-scale calliper, however, the Chinese were in advance of Europe by approximately 1700 years.

## THE MAGIC LANTERN

SECOND CENTURY AD

The magic lantern, or zoetrope, is a device which held audiences spellbound before the modern era, and has always had a particular fascination for children. It can exist in various forms, but essentially it consists of a series of pictures through which light shines, and which move in succession to give the illusion that the figures in the pictures are themselves moving. It is thus the earliest ancestor of the cinema. The pictures can be turned by hand or automatically (as by vanes turned by hot air currents rising from a lantern). The pictures are generally seen projected on a wall or a screen, though street shows in portable boxes have instead a peep-hole through which one peers at the moving pictures inside the box. When projected, it is better that lenses be used, though they are not essential.

In 1868, W.B. Carpenter, the Vice-President of the Royal Society, wrote that the zoetrope, or magic lantern, had been invented by Michael Faraday in 1836, only thirty-two years earlier. This was wrong, since John Bate had described the same thing in his book *Mysteryes of Nature and Art* in 1634. But the real truth is that the zoetrope was invented in China.

The projection of moving images on a screen is recorded as having been practised in 121 BC, when a magician named Shao Ong staged a kind of seance for an emperor in this way. But another early form of magic lantern was in the possession of an emperor who died in 207 BC; after the lamp was lit, one could see the sparkling of scales of turning dragons. The same emperor had a similar object called 'the pipe which makes fantasies appear'. It seems to have had a small windmill or air turbine connected to it, for we are told in the book Miscellaneous Records of

the Western Capital written in the sixth century AD: 'There was a jade tube two feet three inches long, with twenty-six holes in it. If air was blown through it, one saw chariots, horses, mountains, and forests appear in front of a screen, one after another, with a rumbling noise. When the blast stopped, all disappeared.'

The next record we find of a magic lantern occurs in about 180 AD. At that time, the inventor Ting Huan had perfected a 'nine-storied hill censer', which seems to have been a vastly complicated multiple magic lantern. Attached to it were strange birds and mysterious animals, which moved around when a lamp was lit. A similar device is described by T'ao Ku in his book Records of the Unworldly and Strange, published about 950 AD: 'Moving shapes were seen and tinkling noises heard, after the lighting of a candle or lamp'.

By the twelfth century, magic lanterns were called 'horse-riding' or 'horse-pacing' lamps, since after the lamp was lit, a succession of prancing horses was projected round about on the walls, moving as if on their own. Europeans discovered these toys when they began visiting China, and a Jesuit missionary named Father Gabriel de Magalhaens has left this description of one from the middle of the seventeenth century:

The Lamps and Candles, of which there are an infinite number in every Lanthorn [lantern], are intermix'd and plac'd withinside, so artificially and agreeably, that the Light adds beauty to the Painting; and the smoak gives life and spirit to the Figures in the Lanthorn, which Art has so contriv'd, that they seem to

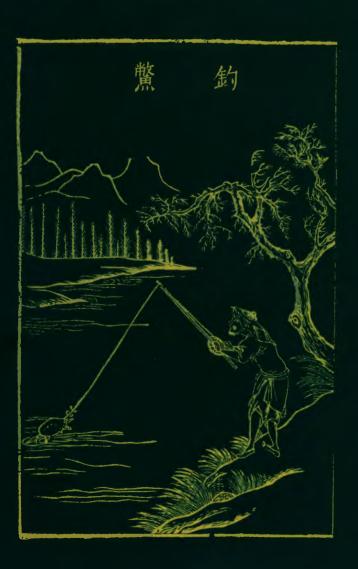

walk, turn about, ascend and descend. You shall see Horses run, draw Chariots, and till the Earth; Vessels Sailing; Kings and Princes go in and out with large Trains; and great numbers of People both a-Foot and a-Horseback, Armies Marching, Comedies, Dances, and a thousand other Divertisements and Motions represented....

The projected slides which lecturers use, which some people still call 'lantern slides', derived from these Chinese magic lanterns. Needham says: 'It is not generally known that the first lecturer to use lantern slides was a Jesuit of the China mission, Martin Martini (16141).... His lectures illustrated by the new technique were given at Louvain in 1654.'

The magic lantern itself was also transported to Europe from China. We do not have all the details.

Did the Chinese use lenses with their magic lanterns? They certainly used them a great deal for a number of other purposes, and Needham thought it possible 'that someone had the idea of placing one or more lenses at the pinhole of a closed chamber.' He goes on to suggest that this occurred during the T'ang Dynasty (618-906 AD). He also stresses that the 'persistence of vision' of the moving successions of images is the basis of cinematography, and that therefore the Chinese may perhaps be considered the earliest pioneers of the cinema.

Their images may only have been painted on pieces of paper or mica, and have gone round and round on a closed loop, but the effect for ancient times was surely profound, as the Jesuit father so vividly testified. We may look upon it as primitive but the ancient Chinese magic lantern had, in its day, a kind of cinematic glory in its turning picture show.

# THE FISHING REEL

THIRD CENTURY AD

The Chinese invented the crank handle in the second century AD. It will therefore not be so surprising that they had invented the fishing reel, a small windlass, by the third century. A painting by the Chinese artist Ma Yuan, dating from about 1195 AD, is perhaps the oldest surviving picture of a fishing reel. Called 'Angler on a Wintry Lake', it clearly shows the use of the reel in the twelfth century. No representation of the fishing reel in the West is known before the year 1651.

The ancient Chinese name for the fishing reel is tiao ch'e. The earliest reference to it found by Needham occurs in Lives of Famous Immortals, which dates from the third or fourth century AD. However, parts of this book have been reliably dated to 35 BC and 167 AD, so it may be that the passage about the fishing reel is older than the book itself.

LEFT (62) This illustration from the *Universal Encyclopedia* of 1601 shows a fisherman catching a river turde. The fishing reel can be plainly seen

A predecessor of the fishing reel is mentioned in the Mo Tzu (Book of Master Mo) which dates from about 320 BC. This book was the canon of a group of warrior-philosophers and proto-scientists, the Mohists, who made many innovations in military technology. One of their machines for warfare was an arcuballista, an early form of artillery which fired groups of javelins at the enemy. Javelins were too valuable to waste, so they were attached to cords and could be retrieved for re-use by means of a reel and windlass – though probably if a javelin was sticking through somebody's chest, it was left there. It is certainly ironical that this military device led to the development of that most peaceable of inventions, the fishing reel.

# LEFT (63) One of the earliest surviving stirrups. It dates from the sixth or seventh century, and is preserved in the Ashmolean Museum, Oxford. This particular stirrup is bronze, but iron was also used.

# THE STIRRUP

THIRD CENTURY AD

For most of the time that man has been riding horses, he has had no supports for his feet. Stirrups were unknown to most of the great armies of ancient times - the Persians and Medes, the Romans, the Assyrians, the Egyptians, the Babylonians, the Greeks. The horsemen of Alexander the Great made their way across the whole of Central Asia without being able to rest their feet while in the saddle. When galloping or jumping, horsemen had to hold the horse's mane tightly to avoid falling off. The Romans devised a kind of hand-hold on the front of the saddle which gave them something of a grip when the going got rough; but their legs just dangled whenever they were not pressed tightly against the horse.

Mounting a horse without stirrups was not so easy either. Fierce warriors took pride in their flying leaps, gripping the mane with the left hand and swinging themselves up; and some bareback riders still do this today. Cavalry-men of ancient times used their spears to help them up, either by hoisting themselves aloft as in pole-vaulting, or by using a peg sticking out of the spear as a foot-rest. Otherwise it was necessary to rely on a groom for a leg-up.

By about the third century AD, the Chinese had remedied this situation. With their advanced metallurgical expertise they began to produce cast bronze or iron

foot stirrups. No inventor of the stirrup is recorded and

the original idea probably

came from the occasional use of a loop of rope of leather to assist in mounting. Of course, such loops could not be used for riding, because if one fell off, one would be dragged along and come to a sticky end. Such loops may have been first used by the Chinese, the Indians, or the nomads of Central Asia bordering on China. The essentials of the stirrup may thus have originated in the steppes, the product of ingenious men whose lives were lived on horseback. Apparently from the third century, the Chinese were casting perfect metal stirrups. The earliest surviving depiction of a stirrup is on a pottery

figure of a cavalryman found in a tomb in Changsha and dated to 302 AD.

An excellent depiction of a stirrup may also be seen in a relief from the mausoleum of the Chinese-Emperor T'ai Tsung (627-49). We may see in Plate 63 (page 101) an actual stirrup of the sixth or seventh century. Stirrups very quickly made their way to Korea, where they are seen in fifth-century tomb paintings. It has also been pointed out that only after stirrups came into use could the game of polo be properly played.

The transmission of stirrups westwards took place with the migrations of a fierce tribe called the Juan-Juan, who came to be known as the Avars (a Turkish word apparently meaning 'exiles'). Their cavalry was devastatingly effective because they had the use of cast-iron stirrups. About the middle of the sixth century, they were driven westwards and moved across south Russia to settle between the Danube and the Theiss. By 560, the Avars were a serious threat to the Byzantine Empire, and the Byzantine cavalry was entirely reorganized in order to counter them. The Emperor Maurice Tiberius prepared a military manual, the *Strategikon* (which still survives, untranslated) in 580, specifying the cavalry techniques to be adopted. He mentions the need to use iron stirrups — the earliest mention in European literature.

Stirrups then spread to the rest of Europe by means of the Vikings and possibly the Lombards. One Avar-style child's stirrup has even been excavated in London, brought by a Viking. But the use of stirrups in Europe (other than by the Byzantines and the Vikings) was long delayed, for reasons which are not entirely clear. Conventional armies of Europe do not seem to have adopted them until the early Middle

Ages. Perhaps the lack of metallurgical expertise was a handicap, with stirrups having to be of wrought rather than cast metal for a long time. Mass production of stirrups was only possible with cast metal.

When we think of medieval Europe we think of knights in armour carrying heavy lances and riding on

OPPOSITE (64) Heavily armoured men on horseback were only able to stay on their horses through the adoption of the stirrup, invented in China in the third century AD. This T'ang Dynasty ceramic figure dates from between the seventh and ninth centuries. (British Museum, London.)

horseback, but that would have been impossible without stirrups, for such heavily weighted riders would have fallen off too easily. It was the Chinese invention of the stirrup which made Western medieval knights possible, and gave us the age of chivalry.

## PORCELAIN

THIRD CENTURY AD

Ordinary pottery is made from clay baked in a kiln at temperatures ranging from 500°C to 1150°C, and is called earthenware. Porcelain is something quite different: it consists of a body of fused clay covered by a glaze, a glassy substance, and is fired at a high temperature — about 1280°C. The secret of making porcelain lies in the use of a pure clay, kaolin or China clay, which when fired at a sufficiently high temperature changes its physical composition, a process known as vitrification, and becomes translucent and totally impervious to water. The reason why China was able to 'invent' porcelain at a very early age compared to the rest of the world was that the Chinese potters both found the clay and were able to produce the high temperature necessary to fuse it.

In practice, pure kaolin is mixed with 'porcelain stone', known in China in recent centuries as *petuntse* or *baidunzi*, a substance which is the intermediate product when igneous rocks decompose into clay over many millennia. Porcelain stone contains a high percentage of feldspar, which supplies the alkali as a flux to lower the vitrification temperature of the clay and the additional silica to enhance the porcelain's translucency after vitrification. Porcelain

stone is also used for preparing high temperature glazes which also contain a strong flux such as wood ash or lime to enable the glaze mixture to turn

LEFT (65) This 1637 engraving from the book. The Creations of Nature and Man (Tieu-kung K'ai-un) shows a small porcelain kiln in operation, the main fire visible on the right. This produces heat rising from the bottom upwards for the first 24 hours. The men are inserting lighted wood through holes or 'skylights' at the top. This wood will burn for a further four hours, to produce the heat which will travel from the top downwards. A clay cup passed through a minimum of 72 separate processes before it became a porcelain cup. Further bundles of sticks lie on the ground at the bottom of the picture.

LEFT (66) Traditional Chinese kilns and firing of porcelain, from a lateeighteenth-century painting.

into a glass when fired at a temperature for porcelain production. The result is porcelain, which can often be seen through. Since the clay is opaque while the glass is transparent, the resulting fusion of the two gives a substance which is partially transparent, or translucent.

Just how astounding this was when first seen by foreigners may be judged from the remarks made by the Arabic merchant Suleiman, who wrote in 851 AD in his *Chain of Chronicles* of porcelain which he had seen in China: 'There is in China a very fine clay from which are made vases having the transparency of glass bottles; water in these vases is visible through them, and yet they are made of clay.'

It was incomprehensible to foreigners that pottery could be translucent and let the light through, since clay was well known to be opaque. This seemed to be a miracle: how could one see through something which everyone knows cannot be seen through? Pots and vases through which the light could pass? Incredible! Absurd!

Porcelain was not a sudden invention which took place at a particular time. It was arrived at gradually in China. Textual evidence is hopelessly confused and vague, owing to problems of terminology, so that archeological discoveries are the only means of determining when porcelain first came into being. Fresh discoveries keep pushing back the dates further into the past. 'Protoporcelain' or 'primitive porcelain' made of kaolin clay, of

compact texture, and surprisingly lustrous, apparently goes back to the eleventh century BC. But these wares do not have the fusion of the clay with feldspar and quartz, so that they are not true porcelains.

Historians of porcelain and ceramics are not always in agreement about when the line was crossed from 'protoporcelain' to proper porcelain. However, it now seems that archeological finds push back the date of true porcelain to the first century AD. By the third century AD, in any case, true porcelain was undeniably in use.

By the Sung Dynasty (960-1279), porcelain had reached heights of artistry which some believe were never surpassed, and have not been equalled since. Porcelain manufacture by this time was a highly organized trade employing hundreds of thousands of people. There were teams of men who specialized in washing the clay, others who concerned themselves only with glazes, others who maintained the kilns, and so on. One kiln of this period which has been excavated could accommodate twenty-five thousand pieces of porcelain at a single firing. It was built on the slope of a hill, the gentle incline of about 15° reducing the speed of the flames through the kiln. The sophistication of the kilns was most impressive. Some were fired by burning of wood, while others were down-draught burners of charcoal. Flues were naturally employed, along with sophisticated layers of insulation, buttresses and clay linings. Control of the firing process

was of the utmost precision. Porcelain could be fired either in oxidizing or de-oxidizing (reducing) flames. In the Ming Dynasty, when the famous blue-and-white ware was largely produced, the best lustrous quality of the cobalt blue pigment could only be obtained at certain specific temperatures, and in a reducing flame. Various metals used as pigments spread themselves chemically throughout the bodies of the porcelain objects in quite different ways depending on whether oxygen is being taken in or given off. A reducing flame forces porcelain to give off oxygen, leading to some of the most beautiful effects. The achieving of certain colours and effects in porcelain is therefore the result of intricate and subtle control of firing conditions of the kilns.

The secrets of porcelain manufacture were jealously guarded, and visitors from Europe such as Marco Polo could but gape and wonder. Porcelain objects were still a very great rarity in Europe by the fifteenth century. They were gifts for kings and potentates. Not until 1520 did the first sample of kaolin clay reach Europe, brought by the Portuguese. Europeans then thought that if only they could find deposits of this white clay, they would be able to make porcelain. Frantic efforts were made to locate deposits, in ignorance of the fact that kaolin clay alone was far from sufficient for the making of porcelain.

The countless experiments carried on with various earths and solid substances in furnaces eventually had a most unpredictable result. Scientists and craftsmen began

to notice that upon cooling down again, molten minerals could crystallize. Until this began to be observed, Western scientists had been convinced that crystals could only be formed from liquids. About the middle of the eighteenth century in Europe, the idea began to gain ground that perhaps the Earth's rocks could have been formed from the cooling of molten masses of lava. Such an idea was heresy, but a heresy increasingly tolerated. It was the year 1776, famous for the American Declaration of Independence, that saw the first publication of a paper (by James Keir) suggesting a kind of declaration of independence in geology:

Does not this discovery of a property in glass to crystallize reflect a high degree of probability on the opinion that the great native crystals of basaltes, such as those which form the Giant's Causeway, or the Pillars of Staffa, have been produced by the crystallization of a vitreous lava, rendered fluid by the fire of volcanoes?

The pottery manufacturer Josiah Wedgwood (who was trying to make porcelain) even became involved in scientific experiments to determine whether the Earth's crust might have been formed from lava flows. And by 1785, James Hutton the geologist presented his revolutionary new theory of the Earth based on these ideas, which we remark elsewhere (page 182) had been

This magnificent porcelain plate dates from the reign of the Emperor Yung-cheng (1723–1735) of the Ch'ing Dynasty. The man kneeling with a banner is a soldier announcing a military victory, which has just taken place, to the two men who are sitting playing the game of wei dr'i, more commonly known by its Japanese

soldier's banner, which was not a very martial choice! The pale lustrous green used for the grass, and the sky as limpid as a daydream, combine to make this plate a triumph of the most refined subtlety. (Nanking Museum.)

arrived at by the Chinese centuries before. And so, one of the great scientific advances in the Western world took place as a direct consequence of the attempts by Europeans to find the secret of porcelain manufacture. It is highly ironical that this great advance itself was merely a late duplication of an indigenous Chinese idea (albeit unknown to Europeans, and soon surpassed in the West).

In Europe, porcelain was finally developed in the eighteenth century, some 1700 years after the Chinese. Previous European 'porcelains' were not true ones: they would melt if placed in ovens at the temperatures used to fire Chinese porcelain. At last the goal had been achieved, and one of the greatest secrets of China fell to a sustained Western onslaught which had lasted for centuries.

# BIOLOGICAL PEST CONTROL

THIRD CENTURY AD

Mandarin oranges are ferociously attacked by black ants, caterpillars and other predators, and if this is not somehow controlled, no orange will be left intact on a tree. For 1700 years, the Chinese have controlled insect pests by biological means, using one insect to kill another. This has only really been practised in the West in the twentieth century. Perhaps the most striking and important Chinese use of biological pest control was in the use of yellow citrus killer-ants to protect the mandarin trees. Here is how a text of 304 AD, *Records of the Plants and Trees of the Southern Regions*, by Hsi Han, describes the use of the carnivorous yellow ants:

The mandarin orange is a kind of orange with an exceptionally sweet and delicious taste.... The people of Chiao-Chih sell in their markets [carnivorous] ants in bags of rush matting. The nests are like silk. The bags are all attached to twigs and leaves which, with the ants inside the nests, are for sale. The ants are reddishyellow in colour, bigger than ordinary ants. These ants do not eat the oranges, but attack and kill the insects which do. In the south, if the mandarin orange trees do not have this kind of ant, the fruits will be damaged by many harmful insects, and not a single fruit will be perfect.

The killer-ants employed for this purpose are still used. They have been identified by Western entomologists as *Oecophylla smaragdina* (see Plate 69 (right)). Originally, whole nests of citrus ants were sold, as we have seen, but later they were caught by being trapped in bladders. This is described by Chuang Chi-Yü in his *Miscellaneous Random Notes* of 1130:

In Kuangchow there is a shortage of arable land so people often plant mandarin oranges and *chii* oranges for income; but they suffer considerable losses caused by small insects feeding on the fruits. However, if there are many ants on the trees then the injurious insects cannot survive. Fruit-growing families buy these ants from vendors who make a business of collecting and selling such creatures.

They trap them by filling hogs' or sheep's bladders with fat and placing them with the cavities open next to the ants' nests. They wait until the ants have migrated into the bladders and then take them away. This is known as 'rearing orange ants'.

But how could the ants spread easily through an entire orange grove? Bridges of bamboo have traditionally been stretched between the orange trees to allow the citrus ants to move from one tree to another throughout the grove. This practice continues today. They were in use at least four hundred years ago, as we learn from Wu Chen-Fang's Miscellanies from the Southern Regions of 1600:

In Li-chih village, west of Kaochow, oranges and pomelos are important secondary crops. Trees planted on several mon (each 6.6 acres) of land are connected to each other by bamboo strips to facilitate the movement of the large ants which ward off insect pests. The ants build

ABOVE (69) Carnivorous citrus ants (*Oecophylla sunaragdina*) used by the Chinese for seventeen hundred years as a means of biological pest control to protect their mandarin orange trees from predators. Some of the ants here hold leaves for a nest, while others sew them together with silk from larvae.

nests among the leaves and branches in the hundreds and thousands. A nest may reach the size of a *tou* (1.6 gallons).

This biological pest control first came to Western attention when a paper on the subject was published in the *North China Herald* on 4 April 1882, by H.C. McCook; but few people noticed it. It was not until a serious outbreak of citrus canker occurred in the Florida citrus groves in the 1910s that a plant physiologist was sent to China by the US Department of Agriculture in 1915 to search for canker-resistant oranges, and discovered the citrus ants. The study of this subject by Westerners was interrupted by the Japanese invasion of China in the 1930s. Then, in 1958, a Chinese scientist, Ch'en Shou-Chien, recommended a renewed study of the ants. Their use in Chinese orange groves continues to this day.

## THE UMBRELLA

FOURTH CENTURY AT

The umbrella as we know it was invented in China towards the end of the fourth century AD. An earlier type, made of silk, had been used as a chariot rain-cover in the rain or many centuries; the umbrella proper appeared during the Wei Dynasty (386–532 AD). Instead of silk, it used a special kind of oiled heavy paper made from the bark of the mulberry tree (see the account of paper, page 92), and was used as protection from both rain and sun.

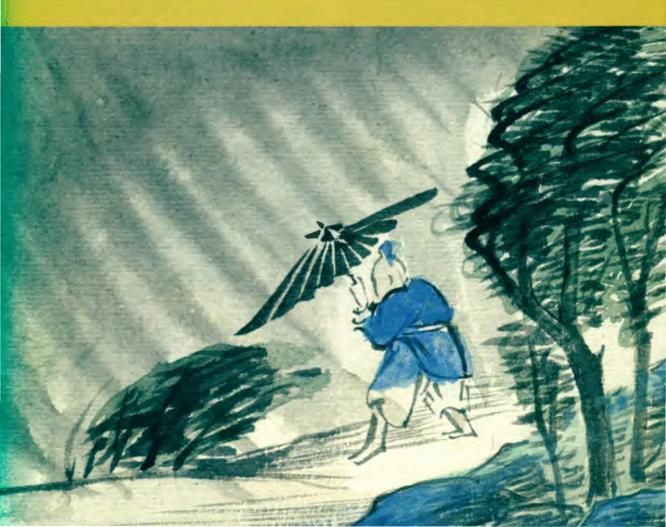

The Wei emperor used an red and yellow umbrella, whereas ordinary people used blue ones. Umbrellas became common, and in 1086 we find the author Shen Kua using the umbrella as a descriptive analogy, referring to the astronomical 'lunar mansions' in the sky as radiating from the celestial pole 'like the spokes of an umbrella'.

ABOVE (71) A late-eighteenth-century painting of an umbrellamender, with a pile of rolled umbrellas on the right. The umbrella was invented in China towards the end of the fourth century AD, probably inspired by the silk canopies placed over chariots during the Han Dynasty (207 BC–220 AD). (Victoria and Albert Museum, London.) BELOW (72) A man holding a fifteenth-century umbrella in a storm. This painting is by the Ming Dynasty Emperor Chu Kao-Chih, and appears in his unpublished 1425 treatise *Essay on Astronomical and Meteorological Presages*, the manuscript of which survives (see another reproduction from it in Plate 11 (page 29)). (Cambridge University Library.)

By the fourteenth century silk umbrellas must have been available as well as the oiled-paper ones, for in 1368 an imperial decree announced that silk umbrellas were to be reserved for the exclusive use of the royal family. This law does not say a lot for the Ming Dynasty, which promulgated it; but perhaps the ruling cliques thought that people with silk umbrellas were getting 'above themselves'. The umbrella seems at this time to have taken on quite a symbolic significance. It was used in ceremonies, and the emperor would give special signed umbrellas to his most trusted officials.

How and when the umbrellas came to Europe is apparently not known. Perhaps paper umbrellas sold in China made their way to Europe, where the design was copied and its origin soon forgotten.

## **MATCHES**

SIXTH CENTURY AD

Every time we strike a match, we are using a Chinese invention. The first version of a match was invented in the year 577 AD by impoverished court ladies during a military siege, in the short-lived Chinese kingdom of the Northern Ch'i. (This kingdom was presided over by the psychopathic ruler described at greater length in the account of man-flying kites on page 191). Hard-pressed during the siege, they must have been so short of

tinder that they could otherwise not start fires for cooking, heating, etc. The neighbouring kingdoms of the Northern Chou and the Ch'en agreed to attack the Northern Ch'i – which consisted of the entire North China plain – from both sides at once. The attack was so successful that the Ch'i were annihilated. Later, the two conquering forces warred against one another and were in turn absorbed in the next unification of China, under the Sui Dynasty (581–617 AD).

Early matches were made with sulphur. A description is found in a book entitled *Records of the Unworldly and the Strange* written about 950 by T'ao Ku:

If there occurs an emergency at night it may take some time to make a light to light a lamp. But an ingenious man devised the system of impregnating little sticks of pinewood with sulphur and storing them ready for use. At the slightest touch of fire they burst into flame. One gets a little flame like an ear of corn. This marvellous thing was formerly called a 'light-bringing slave', but afterwards when it became an article of commerce its name was changed to 'fire inch-stick'.

There is no evidence of matches in Europe before 1530. Therefore, the Chinese were using them for just short of a thousand years before they arrived in Europe. Matches could easily have been brought to Europe by one of the

RIGHT (73) A late-eighteenthcentury painting of a boy selling josssticks and matches. (Victoria and Albert Muscum, London.)

Europeans travelling to China at the time of Marco Polo, since we know for certain that they were being sold in the street markets of Hangchow in the year 1270 or thereabouts. This is recorded in one of the six-and-a-half thousand ancient topographical books which survive about regions and cities of China, *Institutions and Customs of the Old Capital (Hangchow)*, which dates from 1270 and recounts events from 1165 onwards. Since the earliest European matches used sulphur, the invention seems to have been directly transmitted by a European traveller. Sulphur is still used in matches today, though it was in 1830 that Sauria in France and Kammerer in Germany made the breakthrough which gave us the modern match, by using a compounded mixture of yellow phosphorus, sulphur and potassium chlorate.

It is easy for us to take for granted such small, daily necessities as matches. After all, they are cheap, used once and thrown away. But where would we be without them? Many adults in today's developed world carry with them, all unknown as they go about their daily business, small tokens of the inventiveness of a group of anonymous Chinese women of the sixth century – the products of their desperation in the face of starvation and eventual violent death.

#### CHESS

SIXTH CENTURY AD

Although most historians of chess believed that the game was invented in India, Needham has been able to establish that it originated in China. Chess took its present form as a militaristic combat game in India, but its origins were connected with astrology, magnetism and divination. According to Needham: 'The battle element of chess seems to have developed from a technique of divination in which it was desired to ascertain the balance of ever-contending *yin* and *yang* forces in the Universe (sixth-century AD China, whence it passed to seventh-century AD India, generating there the recreational game).'

The surviving form of 'Chinese chess' played today is not the same either as the ancient Chinese forms or as modern Western chess. This has led various scholars to overlook the game's Chinese origins. For instance, A.E.J. Mackett-Beeson, in discussing the history of chess pieces in 1968, remarks: 'Although the Chinese claim to have invented chess some 2072 years ago during the Hansing campaign,

ABOVE (74) A set of seventeenth-century Chinese chessmen, made of ivory pieces set into dark 'heartwood' ebony, kept in an ebony box with a sliding lid. Chinese chessmen were not carved as figures, but were always discs identified by the Chinese characters on top – one player's painted red, the other's painted black. No Chinese chessboard of this age appears to survive, and it is believed that only one other set of chessmen similar to this exists (represented in A. E. J. Mackett-Beeson. *Chessmen*, New York. 1968, – see Plate 89.) (Collection of Robert Temple.)

choke-choo-hong-ki [the name applied to the Chinese game] is merely a variation of shatranj, the medieval game of India. This modern Chinese chess was a reintroduction to China, and was indeed influenced by the Indian game, which had originally come from Chinese sources and been altered in India.

In modern Chinese chess the board has the usual sixty-four squares. Over the middle of the board, however, is a river, which originally symbolized the Milky Way, across which some of the pieces cannot move. For instance, each player has two 'men' called 'horses'. These move just as our knights do, but they cannot cross the river. On the other hand, each player has two chariots which are equivalent to our rooks, and these can cross the river. The king moves one space at a time, as our king does, but is confined to a fortress consisting of four squares, king one and two and queen one and two. Each player has only five pawns; they can cross the river but do not queen. There is the further amusing curiosity that each player has two pieces called 'rocket boys' which do not capture the piece directly ahead but instead capture the one directly beyond it, as if they had fired artillery over the head of the first piece.

Needham believes that the opposing kings of chess were originally the Sun and Moon. The planets were represented by pieces divided between the two sides. The pawns, at fourteen a side, were the twentyeight equatorial constellations. The 'rocket boys', Needham thinks, 'may well have been comets'. He quotes an 'Essay on Chess' by the historian Pan Ku of the first century AD:

bodies. These significances being manifest it is up to the players to make the moves, and this is connected with kingship. Following what the rules permit, both opponents are subject to them - this is the rigour of the Tao.

BELOW (75) An earthenware tomb model of the second century

AD, showing two men playing the board game lin-po ('Six Learned Northerners call chess (ch'i) by the name of Scholars'), which goes back to the third century BC at least. i. It has a deep significance. The board has Needham believes this game to be one of several to be square, for it signifies the Earth, and astrological board games which together its right angles signify uprightness. The led to the development of chess, pieces of the two opposing sides are yellow and which were 'militarized' and black; this difference signifies the yin in India to provide the combat and the yang - scattered in groups all over elements recognizable to us the board, they represent the heavenly today. (British Museum, London.)

In ancient China, there was a wide variety of chess games. Needham stresses that: 'The Chinese language makes no distinction between these forms and the war-game of chess itself, both being expressed by the character ch'i.' So, although the forms of chess vary enormously, not only do the Chinese designate them all by the same name, but they may clearly be seen to be related. It was not the specific rules, number of men, and modes of play that were the main point to the game, but the magical purpose of foretelling future events.

As for a date for the Chinese origins, Needham says: 'The oldest Chinese name for a chess-like game played on a board is *i*, to which there are two references in Mencius (fourth century BC)...'. An improved version known as 'image-chess' seems to have been invented in the sixth century AD. At that time, a cavalry general named Yü Hsin wrote an essay entitled 'The Image-Chess Game'. An emperor, or one of his advisers, actually seems to have invented this later form of chess. As a book entitled *Red Lead Record* tells us:

Tradition handed down says that image-chess was invented by the Emperor Wu of the Northern Chou Dynasty [561–78 AD]. According to the [official history] it was in 569 AD that the Emperor finished writing his Image-Chess Manual. He assembled all his officials in a palace hall and gave lectures to them about it ... in image-chess images of the Sun, Moon, stars, and constellations were used ... it was necessary to have scholarly commentaries on it, and lectures to the hundred officials.

Just as modern Chinese chessmen are often flat wooden discs, so many ancient Chinese chessmen are simply bronze discs bearing written characters saying what they represent. Several examples are in the British Museum, where they have been mislaid and forgotten in recent years. Some have pictures of constellations. Many have been found with the picture of the Great Bear (the Plough or Big Dipper), which, as we see in the account of the compass (page 162), was represented on the lodestone pointer in early Chinese compasses. Although the Chinese origin was forgotten, the astrological importance of chess was realized by the Indians and Arabs. Indeed, there is a thirteenth-century Latin poem which gives

the astrological symbolism of each chess piece, showing that this knowledge still existed at that time even in Europe.

The earliest European references to chess date from about 1010 in the Pyrenees. The game seems to have entered Spain through contact with the Arabs, who obtained it from India, where it was known as *chaturanga* from the early seventh century AD.

In summarizing the unique factors in China which enabled a game such as chess to develop, Needham says that 'the important thing to notice is that in China, and in China alone, on account of the dominance of the *yin-yang* theory of the macrocosm, could a divination technique or "pre-game" have been devised which was both astrological and yet had a sufficient combat element to enable it to be vulgarized into a purely military symbolism.'

## BRANDY AND WHISKY

SEVENTH CENTURY AD

Readers will be doubly surprised to learn that the Chinese invented brandy, because though the fact in itself is impressive enough, it is not widely realized that the Chinese drank wine made from grapes at all, much less distilled it into brandy. Grape wine was being drunk by the second century BC at the latest in China, since we begin to have textual evidence of it by then. The envoy and traveller Chang Ch'ien brought good wine grapes (Vitis vinifera) back with him from Bactria about 126 BC. Before the importation of those grapes, however, there were wild vine species, or 'mountain grapes', which were already being used for wine, namely Vitis thunbergii and Vitis filifolia. Wine made from them is mentioned before Chang Ch'ien in the book called Classical Pharmacopoeia of the Heavenly Husbandman.

The fact that an even stronger drink could be obtained from wine first came to attention through the production of 'frozen-out wine' among the Central Asian tribes. No doubt because of the extremely cold conditions in which these people lived, it was often noticed that wine and other fermented beverages (such as fermented mare's milk) when frozen would have small amounts of unfrozen liquid in the middle. This was the alcohol, which had remained liquid while the water in the drink had frozen. It was presumably this to which Chang Hua was referring in 290 AD in his book *Records of the* 

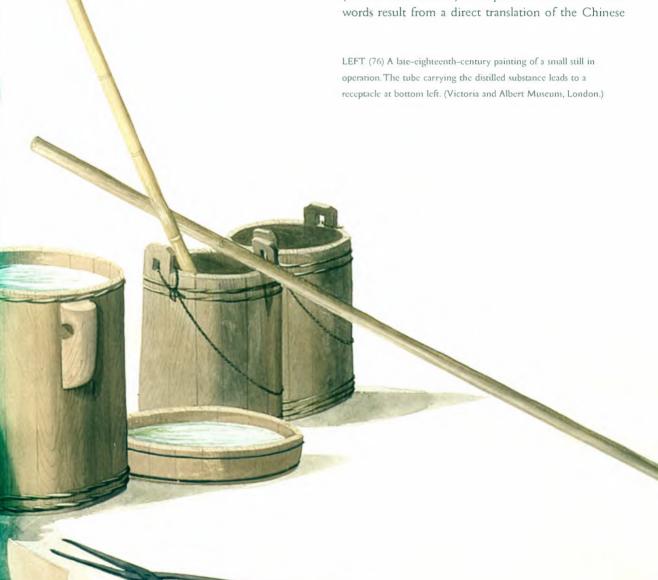

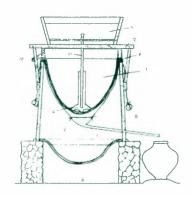

Investigation of Things, when he said: 'The Western regions have a wine made from grapes which will keep good for years, as much as ten years, it is commonly said; and if one drinks of it, one will not get over one's drunkenness for days.'

The tribal peoples of Kao-Ch'ang (Turfan) presented 'frozen-out wine' as tribute to Chinese emperors more than once, commencing in 520 AD. The freezing-out technique for obtaining spirits eventually became a test applied to distilled spirits. Yeh Tzu-Ch'i tells us in his book of 1378, entitled *The Book of the Fading-like-Grass Master*, that people would test their spirits by leaving them outside in the winter to freeze. If they did not freeze, they knew the distilled spirits were pure and unadulterated, but if they partly

froze, they knew they were watered-down or otherwise impure. 'Frozen-out wine' is not mentioned in Europe until Paracelsus, in the *Archidoxis*, written in 1527 but not published until 1570. Paracelsus's remarks caused something of a sensation among Europeans. So unfamiliar was the phenomenon he described that Francis Bacon in 1620 wrote, half-incredulous: 'Paracelsus reporteth, that if a glass of wine be set upon a terras [terrace] in bitter frost, it will leave some liquor unfrozen in the centre of the glass, which excelleth *spiritus vini* drawn by fire.' (For by then, distillation of alcohol was known.)

Distilled wine, or brandy, was known in China as 'burnt wine'. The English word 'brandy' itself comes from the Dutch brandewijn ('burnt wine'). And the German word for brandy or spirits is Branntwein ('burnt wine'), while a distiller is a Branntweinbrenner ('burnt wine burner'). It is possible that all of these words result from a direct translation of the Chinese

ABOVE (FIG. 5) A diagram of a Chinese still from *China at Work* by R.P. Hommel. The distilled substance, which can be any of a number of substances, including brandy or whisky, is drawn off by the side-tube (2) at the bottom, into a cool vessel. The fire and grate (6) are underneath a cast iron bowl (3) which forms the bottom of the still and is filled with the mash to be distilled. At the top is a wooden reservoir of cold water (5) supported by a wooden framework (7) and in the middle is a pewter cooling reservoir (1). A central pipe (11) lets cold water flow down into the cooling reservoir or condenser at the still head.

shao chiu ('burnt wine') by Dutch sailors. If not, they are a curious coincidence indeed.

We have a description of the making of 'burnt-wine' brandy by the author Li Shih-Chen, in his book *The Great Pharmacopoeia*:

Strong wine is mixed with the fermentation residues and put inside a still. On heating, the vapour is made to rise, and a vessel is used to collect the condensing drops. All sorts of wine that have turned sour can be used for distilling. Nowadays in general glutinous rice or ordinary rice or glutinous millet or the other variety of glutinous millet or barley are first cooked by steaming, then mixed with ferment and allowed to brew in vats for seven days before being distilled. The product is as clear as water and its taste is extremely strong. This is distilled spirits (chiu lu).

Here we have a description not only of brandy, but of various kinds of whisky. This passage was published in 1596, but is merely one of the clearest passages describing distilled spirits which had been made in China from the seventh century AD. Many passages are rather obscure and coy because of the problems over the excise duty on spirits which was levied by

the government. The Chinese were the world's first large-scale bootleggers. The Emperor Wang Mang (who reigned 9–23 AD) nationalized the fermentation and brewing industries. So strict were the taxes and the prohibitions against private manufacture of wine or spirits during the Northern Wei Dynasty (386–535 AD) that the penalty for private brewing was death. People had to evolve a series of 'cover-names' for brandy and whisky just as in modern times the terms 'hooch', 'white lightning', and 'moonshine' have developed. One type of drink was called 'the Sage', another was called 'the Worthy'. And in the eleventh century, if you wanted to offer your guests a drink of your own moonshine, you would say, 'Have a drop of "wisdom soup"'.

The distillation of alcohol in the West was discovered in Italy in the twelfth century. Spirits came to be known as aqua ardens ('the water that burns') or aqua vitae ('the water of life'). By the thirteenth century, several writers mention it, and talk about brandy ten times distilled, until it reached what must have been about 90 per cent alcohol. The word 'alcohol' (which derives from Arabic) was introduced by Paracelsus in the sixteenth century. By 1559, aqua vitae was being praised by Conrad Gesner in terms which we can all find familiar: 'Yea, it changeth the affections of the minde, it taketh away sadnes and pensivenes, it maketh men meri, witty, and encreaseth audacitie...'. And in this increased audacity, wit and merriment, the Chinese were in advance of Europeans by about five hundred years.

#### THE MECHANICAL CLOCK

EIGHTH CENTURY AD

The difficulty in inventing a mechanical clock was to figure out a way in which a wheel no bigger than a room could turn at the same speed as the Earth, but still be turning more or less continuously. If this could be accomplished, then the wheel became a mini-Earth and could tell the time. For, after all, the time is nothing more nor less than how far the Earth has turned today.

Accomplishing this mechanical feat was one of the greatest steps forward of the human race. Where would we be today without clocks? The mechanical clock was invented in China in the eighth century AD. But still in 1271, Robertus Anglicus in his commentary on the *Sphere* of Sacrobosco tells us that in Europe 'artificers are trying to make a wheel

which will pass through one complete revolution for every one of the [Earth's], but they cannot quite perfect their work. If they could, it would be a really accurate clock, and worth more than any astrolabe or other astronomical instrument for reckoning the hours...'.

By 1310, this had finally been achieved in Europe. And the stimulus for it seems to have been some garbled accounts of Chinese mechanical clocks which came to the West by way of traders. This was the same century that brought to Europe the

BELOW (77) A model of the 'Cosmic Engine', Su Sung's great astronomical clock of 1092. The framework has been left uncovered to reveal the mechanisms. The original clock tower was 30 feet high. At the top is the power-driven armillary sphere for observing the positions of the stars. In the original, this was bronze, and the power for turning it was transmitted by a chain-drive. Mid-right (B) may be seen a celestial globe which was inside the tower and turned in synchronization with the sphere above. The central element in the reconstruction (D) is the water wheel escapement, which, though turned by water power, was a mechanical escapement. This was a mechanical clock rather than a water clock, even though its power came from falling water or mercury. (Science Museum, London.)

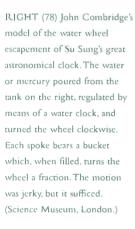

Chinese inventions of gunpowder, segmental arch bridges, cast iron, and printing.

Apart from the fact that the Chinese are obviously an inventive people, what other factors can account for the fact that they were the first to invent mechanical clocks? Was there some special reason why they urgently needed to know the hours of the day and the days of the year with a precision not required in Europe? The answer is yes, but few could possibly imagine why.

The Chinese emperor was a cosmic figure, the equivalent on Earth of the Pole Star. His every move was regulated in conjunction with astrology. His heir was not necessarily his eldest son. Many examples in Chinese history exist of fourth sons, or other lesser offspring, being selected as the next emperor. How, then, was it determined who should be the heir? Part of the process of selection involved the astrological computation of the moment of the child's conception (since in China horoscopes commence at the

conception rather than at birth). And the moments when conception might take place were carefully set aside for the highest-ranking wives and concubines of the emperor to sleep with him. Access to the emperor's person had to be precisely timed in order for this to work properly. From the *Record of Institutions of the Chou Dynasty* compiled about the second century BC, we find the following astonishing passage about the emperor's sex life:

The lower-ranking women come first, the higher-ranking come last. The assistant concubines, eighty-one in number, share the imperial couch nine nights in groups of nine. The concubines, twenty-seven in number, are allotted three nights in groups of nine. The nine spouses and the three consorts are allotted one night to each group, and the empress

estimated time of

also alone one night.

On the fifteenth day of every month the sequence is complete, after which it repeats in the reverse order.

The emperor, known as the Son of Heaven, was full of a powerful yang force, which was the essence of masculinity. But he needed to be fed with a matching yin force, the essence of femininity, to achieve a balance. At the time of the full moon, when the yin force was at its peak, the empress would sleep with the Son of Heaven, feeding him with her powerful yin. This would be the most propitious time for a conception to take place. The lesser women, during the time of the Moon's waning, had to sleep with the emperor in groups in order to pool their respective yin forces to overcome the lack of the Moon's strength. For most of the nights of his life, therefore, the emperor slept with nine women at a time.

If a likely lad were to be chosen to be the next emperor, the astrologers would go back to the precise time of his conception, plot the stars which were culminating and consider any comets or novae, or other astronomical phenomena. If the astrological configurations were indicative of a strong leader, a valiant warrior, or whatever, this would weigh in the young prince's favour. But the eldest son might well have been born under the influences of stars concerning death or disaster. So he would be ruled out quite early on.

But let us see what the situation was at about the time when the mechanical clock was invented in China. Was the succession principle operating very well? In the ninth century, Pai Hsing-Chien bewails the chaos of the system. We read in his Poetical Essay of the Supreme joy:

Nine ordinary companions every night, and the empress for two nights at the time of the full moon – that was the ancient rule, and the secretarial ladies kept a record of everything with their vermilion brushes.... But alas, nowadays, all the three thousand palace women compete in confusion.

Clearly, the succession to the throne was in peril. Bad princes might be chosen. The timing of their conceptions was not being noted properly. Time for a clock to be invented! And in 725 AD, this was done.

The Chinese did not invent the first clock of any kind, merely the first mechanical one. Water clocks

had existed since Babylonian times, and the earliest Chinese got them indirectly from that earlier civilization of the Middle East, just as they got much of their earliest forms of astronomy from them. The Chinese certainly did invent improved water clocks of various kinds, including a 'stop-watch' portable one which used mercury rather than water and measured small periods of time. It used weighted balances, or steelyards, rather than just a rising indicator in a bucket as water flowed in and buoyed it up. But these were improvements of an invention which was not originally Chinese. Nor did the Chinese invent the clock dial. That was an invention of either the Greeks or the Romans, and is mentioned by the architectural writer Vitruvius in the first century BC.

The world's first mechanical clock was built by the Chinese Tantric Buddhist monk and mathematician I-Hsing. This was actually an astronomical instrument which served as a clock, rather than simply a clock. A contemporary text describes it:

[It] was made in the image of the round heavens and on it were shown the lunar mansions in their order, the equator and the degrees of the heavenly circumference. Water, flowing into scoops, turned automatically, rotating it one complete revolution in one day and night [24 hours]. Besides this, there were two rings fitted around the celestial sphere outside, having the sun and moon threaded on them, and these were made to move in circling orbit. Each day as the celestial sphere turned one revolution westwards, the sun made its way one degree eastwards, and the moon 131/19 degrees eastwards. After twenty-nine rotations and a fraction of a rotation of the celestial sphere the sun and moon met. After it made 365 rotations the sun accomplished its complete circuit. And they made a wooden casing the surface of which represented the horizon, since the instrument was half sunk in it. It permitted the exact determinations of the time of dawns and dusks, full and new moons, tarrying and hurrying. Moreover, there were two wooden jacks standing on the horizon surface, having one a bell and the other a drum in front of it, the bell being struck automatically to indicate the hours, and the drum being beaten automatically to indicate the quarters.

All these motions were brought about by machinery within the casing, each depending on wheels and shafts, hooks, pins and interlocking rods, stopping devices and locks checking mutually [i.e. the escapement].

Since the clock showed good agreement with the Tao of Heaven, everyone at that time praised its ingenuity. When it was all completed in 725 AD it was called the 'Water-driven Spherical Birds'-Eye-View Map of the Heavens' and set up in front of the Wu Ch'eng Hall of the Palace to be seen by the multitude of officials. In 730 AD candidates in the imperial examinations were asked to write an essay on the new astronomical clock. The text continues:

But not very long afterwards the mechanism of bronze and iron began to corrode and rust, so that the instrument could no longer rotate automatically. It was therefore relegated to the museum of the College of All Sages and went out of use.

From this description we may see that the first mechanical clock was a transition from the water clock to the purely mechanical clock of Europe which used no water power anywhere. However, this does not mean the clock of I-Hsing was a water clock by any means. What it means is that the first mechanical escapement for the clock was worked not by a falling weight or by springs, but by water power. This is quite a different thing from having an actual water clock whose time indicator rises with the level of water (or mercury) in a tank. It is not unreasonable that in developing a mechanical clock, the Chinese turned to water as a power source, since all previous clocks had been water clocks, and the association of ideas was natural to them. The perpetual flow of water was likened to the perpetual turning of the heavens. As Su Sung wrote in 1092 in speaking of his own improved clock:

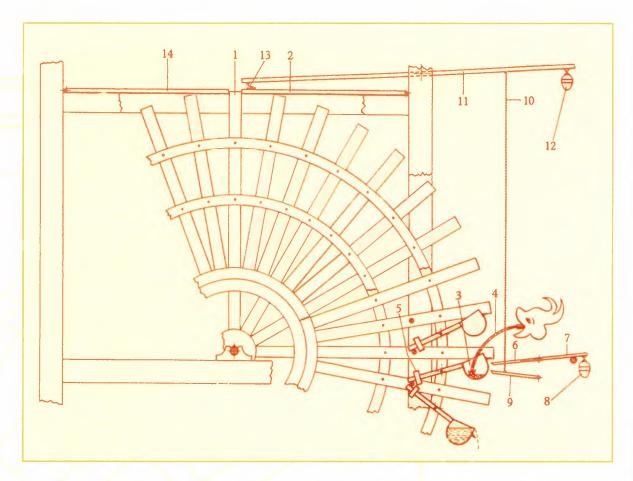

The principle of the use of water power for the driving mechanism has always been the same. The heavens move without ceasing and so also does water flow and fall. Thus if the water is made to pour with perfect evenness then the comparison of the rotary movements of the heavens and the machine will show no discrepancy or contradiction; for the unresting follows the unceasing. The actual workings of the clock of I-Hsing consisted of a vertical water wheel which instead of paddles (such as are turned by a rushing stream) had cups at the ends of the blades. These cups were filled by water dripping from a water clock. I-Hsing's clock was therefore a mechanical clock driven by a water clock. When one of the cups was sufficiently full, it would weigh enough to turn the great wheel by one notch, overcoming the resistance of a restraining tooth which had held the wheel still while the cup filled. Various gear arrangements would then transmit the movement to the time indicators, etc. As the ancient text tells us, shafts, hooks, pins, and interlocking rods were all part of the apparatus. Some idea of what these may have been like may be gathered from the fuller description of Su Sung's clock which we shall see opposite. (See Figure 6.)

This clock of I-Hsing would have been a poor time-keeper, moving jerkily and representing more the first realization of a wonderful idea than a superb piece of machinery. It was because of the enormous promise that this clock offered for future improvements that contemporaries would have had every reason to be excited. And its promise was more than borne out in succeeding centuries. I-Hsing himself died only two years later, and was unable to construct a 'second generation' model.

I-Hsing's clock was, like water clocks, subject to the vicissitudes of the weather. In order to keep the water in them from freezing, torches generally burnt beside them. This was of course not necessary for the small mercury clocks, as mercury does not freeze at any temperature likely to occur in the Earth's weather. Therefore, in the next great clock of which we have accounts in China, mercury was substituted for water because of the freezing problem. This clock was built by Chang Ssu-Hsün in 976 AD). It represented a considerable elaboration and improvement over I-Hsing's machine, though the latter no longer existed and had been lost even before the end of the T'ang Dynasty in 906.

Chang Ssu-Hsün's clock was apparently much larger than I-Hsing's. It was certainly far more complex. The dynastic history of the time describes it:

...a tower of three storeys each over ten feet in height, within which was concealed all the machinery. It was round at the top to symbolize the heavens and square at the bottom to symbolize the earth. Below there was set up the

lower wheel, lower shaft, and the framework base. There were also horizontal wheels, vertical wheels fixed sideways, and slanting wheels; bearings for fixing them in place; a central stopping device and a smaller stopping device [i.e. the escapement] with a main transmission shaft. Seven jacks rang bells on the left, struck a large bell on the right, and beat a drum in the middle to indicate clearly the passing of the quarter-hours. Each day and night [i.e. each 24] hours] the machinery made one complete revolution, and the seven luminaries moved their positions around the ecliptic. Twelve other wooden jacks were also made to come out at each of the double-hours, one after the other, bearing tablets indicating the time. The lengths of the days and nights were determined by the varying numbers of the quarters passing in light or darkness. At the upper part of the machinery there were the top piece, upper gear-wheels, upper stopping device [escapement], upper antirecoil ratchet pin, celestial ladder gear case [possibly the first chain drive in history, or

ABOVE (FIG. 6) John Combridge's diagram of the water wheel escapement of Su Sung's clock. The buckets on the ends of the spokes are shown for the three lowest spokes, the first empty, the second filling from the spout of the tank, and the third full (upon turning further, it would empty into a trough). When the bucket was filled, it depressed a lever which pulled the long chain (10), which then pulled the upper balancing lever (11), which was counterweighted (12). When this happened, the upper lock (2) was jerked away, enabling the wheel to turn. There was another upper lock (14) to prevent recoil of the wheel. Each bucket had its own counterweight (5) to regulate the exact amount of water necessary for tipping the bucket downwards to operate this series of movements.

otherwise this was invented shortly afterwards by Su Sung for his clock], upper beam of the framework, and the upper connecting-rod. There were also on a celestial globe the 365 degrees to show the movements of the sun, moon, and five planets; as well as the Purple Palace [north polar region], the lunar mansions in their ranks and the Great Bear; together with the equator and ecliptic which indicated how the changes of the advance and regression

of heat and cold depend upon the measured motions of the sun. The motive power of the clock was water, according to the method which had come down from Chang Hen in the Han Dynasty through I-Hsing ... but ... as during the winter the water partly froze and its flow was greatly reduced, the machinery lost its exactness, and there was no constancy between the hot and the cold weather. Now, therefore, mercury was employed as a substitute, and there were no more errors....

All of these efforts were preparatory for the greatest of all Chinese medieval clocks, the 'Cosmic Engine' of Su Sung, built in the year 1092. Su Sung's clock is known in considerable detail due to the miraculous preservation, over nine centuries, of his book New Design for a Mechanized Armillary Sphere and Celestial Globe. This work describes the design and construction of the great clock in full detail. Some drawings in the book have recently been discovered to be those of Chang Ssu-Hsün in 976, to whose earlier clock Su Sung's must have borne a closer resemblance than had been thought until now. Modern working models of the clock have been constructed, and in Plates 77 and 78 (pages 117-118) may be seen one at the Science Museum in London. These models are, of course, based on the full descriptions and drawings in Su Sung's book.

Su Sung's clock was actually an astronomical clock tower more than 30 feet high, like the previous one of Chang. But on top of Su Sung's tower was additionally a huge bronze power-driven astronomical instrument called an armillary sphere (see page 38), with which one could observe the positions of the stars. A celestial globe inside the tower turned in synchronization with this sphere above, so that the two could constantly be compared. We are told that the observations made on the demonstrational globe inside and by the observational sphere above 'agreed like the two halves of a tally'.

On the front of the tower was a pagoda structure of five storeys, each having a door through which mannikins and jacks appeared ringing bells and gongs and holding tablets to indicate the hours and other special times of the day and night. All of these time-indicators were operated by the same giant clock machinery which simultaneously turned the sphere and the globe.

This machinery consisted, as usual, of a huge vertical water wheel with scoops at the end of each

blade, into which water dripped from a water clock. Every time the wheel turned one notch upon the filling of a scoop, there was a ratchet-pin which came down to prevent the wheel recoiling backwards. As for the forward motion of the wheel, it went forward one scoop every quarter of an hour. Needham describes the machine as follows:

The wheel was checked by an escapement consisting of a sort of weigh-bridge which prevented the fall of a scoop until full, and a trip-lever and parallel linkage system which arrested the forward motion of the wheel at a further point and allowed it to settle back and bring the next scoop into position on the weigh-bridge. One must imagine this giant structure going off at full-cock every quarter of an hour with a great sound of creaking and splashing, clanging and ringing; it must have been very impressive, and we know that it was actually built and made to work for many years before being carried away into exile.

In fact, Su Sung's clock ran from 1092 until 1126 when the capital, K'aifeng, was lost by the Sung Dynasty. The clock was then dismantled, moved to Peking, and reassembled there, where it ran for some years further. The clock had previous vicissitudes which shed light upon the spirit of the times. Members of political factions opposed to the one of which Su Sung had been a member (he was a conservative) wanted to destroy his clock for political reasons. We are told this by Chu Pien in his book *Talks about Bygone Things beside the Winding Wei* (river in Honan) of 1140:

But at the beginning of the Shao-Sheng reignperiod [1094 AD] Ts'ai Pien, Minister of State, suggested that the armillary clock of Su Sung ought to be destroyed as something which belonged to the previous Yuan-Yu reign period [of only two years before]. At that time Ch'ao Mei-Shu was Assistant Director of the Imperial Library, and as he greatly admired the accuracy and beautiful construction of Su Sung's instruments, he struggled to argue against Ts'ai Pien, but at first his efforts proved unsuccessful. However, he sought the help of Lin Tzu-Chung who talked to Chang Tun, the Prime Minister, and thus the destruction of the clock

was averted. However, after Ts'ai Ching and his brother came into power nobody dared to say anything to prevent Su Sung's machinery being torn down. How shameful!

Thus do we see how personal envy and political disagreement between a liberal and a conservative could result in the destruction of one of the greatest mechanical contrivances in the history of mankind, within only a few years of its construction. But by the strenuous efforts of generations of scholars, Su Sung's book with its diagrams and detailed text survived intact from 1094 until the present time, when Joseph Needham has translated and published it in his book *Heaveuly Clockwork*.

Su Sung's clock was possibly the greatest mechanical achievement of the Middle Ages anywhere on the globe (for further details of its working see pictures and captions accompanying this text); knowledge of its principles spread to Europe leading to the development of mechanical clocks in the West two centuries later.

were often incorporated in the designs on Chinese bronzes. But a close study of these bronzes shows that the characters were set into the moulds either separately or in small groups. (This was especially the case when the 'lost–wax' method of bronze casting was used.) We therefore find bronze inscriptions using the forerunner of movable type as early as the seventh century BC. Individual typecasting was therefore in progress nearly two millennia before it was adopted for printing.

Other means of mass-producing written scriptures and sacred texts were by ink rubbings from stone carvings of the original writings. Stone inscriptions of promulgated decrees occur from at least the third century BC. By the second century AD, stone was used to preserve permanent canonical versions of Buddhist, Taoist, and Confucian texts. Between the years 175 and 183, the complete texts of the seven main Confucian classics, amounting to 200,000 characters, were engraved on forty-six stone tablets. These do not survive, but a similar set made between 833 and 837 still exists near Sian, and is known as the Forest of

# **PRINTING**

EIGHTH AND ELEVENTH CENTURIES AD

Woodblock printing on paper and silk arose in China around the seventh century AD, and actual specimens survive from the eighth century. But the origins of printing go even further back into the distant past: there were many related techniques which preceded printing.

First, seals were used to stamp impressions of names, and even as many as a hundred Chinese characters at once, onto various surfaces. The Chinese got the idea of seals from the Middle East, where the Babylonians and Sumerians used them in profusion long before Chinese civilization arose. Cutting a seal is rather like cutting a woodblock in printing, and it is easy to see how the latter technique derived its inspiration from the former. But that is quite different from saying that the idea of using seals led to printing. This did not happen with the Sumerians or Babylonians. It was the need to make enormous numbers of copies of certain writings which led the Chinese to invent ways of mass-producing written material on paper, a substance which already existed in China (see page 92).

Another proto-printing technique in China was connected with bronze casting. Chinese characters

Stone Tablets. Also still surviving are 7000 stone tablets of Buddhist scriptures carved between the sixth and eleventh centuries.

The Chinese were the world's leading experts at stone-rubbing. The devout of all Chinese religions came with their ink and sheets of paper and made as many copies of the standardized sacred texts as they wanted. And indeed this was done constantly. But just as supply sometimes generates demand, so the availability of rubbings and scriptures seems to have acted as a tempting teaser: many people could now have the scriptures in their homes. But many was not most; for every person who had a rubbing there must have been a dozen who were encouraged to want their own. This new demand must have been an important stimulus leading to the development of actual printing.

The Chinese also used stencils and composite inked squeezes, the former being used particularly by the Buddhists. Paper had a pattern made in it consisting of rows of tiny dots. It was then pressed down on top of a blank sheet, ink was applied to the back, and a stencilled design in ink was the result. This was indeed very close to printing, for it enabled the cheap reproduction of a quantity of clear images – such as the Buddha sitting in meditation.

The composite inked squeezes were remarkable in that in a curious sort of way they anticipated photography. Using these sophisticated techniques, three-dimensional objects could be represented on flat paper with perspective, but with no problems of focus (i.e., no 'depth of field' problem existed). Rubbings would be taken of round bronze vessels whereby the more distant parts would be inked more lightly, and the nearer parts more heavily - giving the perspective effect to an eerie and uncanny degree. Inscriptions and decorations in three dimensions represented on paper could be carried around and kept in multiple copies in the home. This technique was known as 'whole shape rubbing' and it necessitated very careful study and preparation before being attempted. It ranks as one of the most highly skilled crafts ever practised anywhere. A good 'whole shape rubbing' looks so startlingly like a photograph in perfect focus that it seems nothing short of an inventor's miracle.

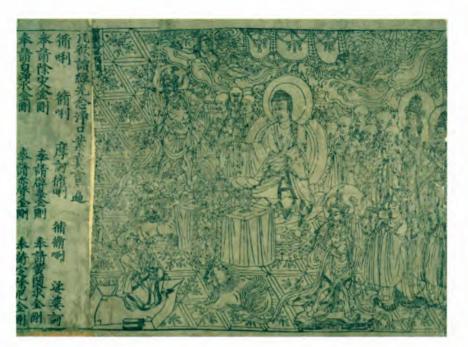

All of these techniques were still not sufficient for the needs of the Chinese. Foremost in pushing back the frontiers of printing technology were the Buddhists; they simply had to have many more copies of their sacred texts than hand-copiers and protoprinting could produce. Therefore it was no accident that the earliest printed text in the world was a Buddhist charm scroll printed in China and preserved in the Pulguk-sa Temple in Kyongju, south-east Korea, where it was discovered in 1966. It was printed some time between the years 704 and 751.

The print runs of the eighth century were quite literally fantastic — almost unimaginable, even by modern standards. The Buddhists took the new technology to Japan where the same Buddhist sutm of the Korean scroll was used as the source of a printed charm, and produced in a print run of one million copies! Many of these copies still survive today, even though they were printed in 764 AD.

The first complete printed book is thought to be the Buddhist *Diamond Sutra*, printed in the year 868 and discovered by Sir Aurel Stein in 1907. It is preserved in perfect condition in the British Museum. It consists of a scroll 17½ feet long and 10½ inches wide and contains the complete text of a Sanskrit work translated into Chinese, with a very elaborate and impressive frontispiece showing the Buddha in discourse with his disciple Subhuti, surrounded by attendants and divine beings. It bears a colophon at the end which says: 'On the fifteenth day of the fourth moon of the ninth year of Hsien-t'ung [868 AD], Wang Chieh reverently made this for blessings to his parents, for universal distribution.'

There were also large print runs for ordinary books. For instance we know that between 847 and 851 several thousand copies were printed of a biography of the alchemist Liu Hung. Calendars were also very popular in printed form, and were even personalized. One calendar surviving from the year 882 is headed: 'Family calendar of Fan Shang of Ch'engtu-fu in Hsi-ch'uan, province of Ch'ien-nan'. So many of these privately printed calendars were circulated that as early as 835, a regional official in the southern province of Szechuan suggested that they be banned - because they were being sold in marketplaces before the Board of Astronomers could approve and issue them, thus pre-empting and anticipating the government's important prerogative. (Chinese emperors looked upon it as a sacred and politically essential matter to revise and promulgate calendars; hundreds were produced during Chinese history.)

By the tenth century, belles lettres and philosophy were fully represented in print. Collections of the works of individual poets were being printed for them and circulated to friends. The scholar Ho Ning

LEFT (80) The frontispiece of the world's oldest surviving book printed on paper, the Diamond Sutra, discovered at Tunhuang by Sir Aurel Stein in 1907. The book is in the form of a roll with a total length of 171/2 feet, and it was printed in the year 868. The frontispiece depicts the Buddha discoursing with his disciple Subhuti, and surrounded by divine beings, monks and officials in Chinese dress. This is the earliest woodcut illustration in a printed book. (British Library, London.)

(898–955) collected his poems and songs and had printed several hundred copies as gifts for his friends; in 913, the Taoist monk Tu Kuang P'ing printed his own commentary upon the classic of Lao Tzu, the chief Taoist sage.

During the tenth century, the prime minister Feng Tao decided to print the eleven classics of Confucianism, together with two supplementary books. Feng Tao managed to survive ten reigns of five different dynastics – a miracle of political survival in a troubled time – which alone enabled him to complete his gigantic task. Finally, after twenty-two years, the Confucian classics were printed in 953. Filling 130 volumes, they were the world's first official printed publications, sold to the public by the Chinese National Academy.

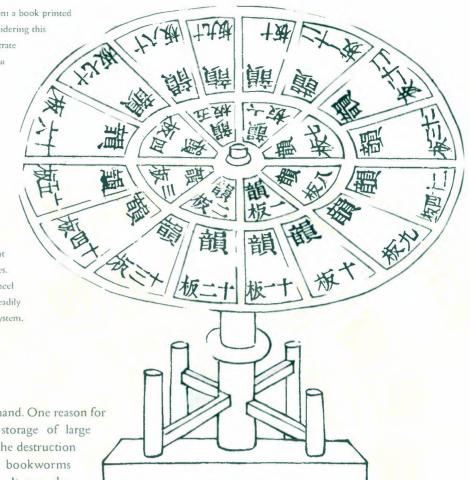

By this time, printing had come of age. Vast quantities of certain works continued to be issued, ranging into many millions of copies. Of one Buddhist collection of the tenth century, over 400,000 copies still survive. So we can imagine what the initial print run must have been! Twenty thousand copies of a printed picture of a goddess on silk still survive from that century, and 140,000 of a picture of a pagoda from the same period. Three other works of that time survive in quantities of 84,000 copies each. Also, during the tenth century, paged books were produced in the modern style, replacing the earlier printed scrolls. This, then, was the establishment of a woodblock

printing industry which in the quantities produced rivalled the most modern efforts of our own times.

The blocks used by the Chinese for their printing tended to be made of fruit woods. Coniferous woods were found unsuitable, because they were impregnated with resin which affected the evenness of the ink coating. For cutting delicate lines in illustrations, a favourite material was the extremely hard wood of the Chinese honey locust tree. For regular text, the soft and easily worked boxwood was often used. But the best all-round wood for block printing was pear: this has a smooth and even texture with a medium hardness, and can be carved in any direction with no grain problems. The slightly harder wood of the jujube date tree was probably the second most commonly used. Naturally, there had to be no knots or spots in the wood, and after cutting the blocks it was customary to soak them in water for a month. But if there was insufficient time, they were boiled, then left to dry in a shaded place and planed on both sides, for it was common to print pages simultaneously on each side of a block. Vegetable oil would be spread over the planed surface, which would be polished with the stems of polishing grass (Achnatherum).

Printing blocks were normally kept for long periods of time – sometimes centuries – in the same family. Large print runs of books tended not to be the rule: a few tens of copies would be run off, then the blocks would be stored away until a few dozen

RIGHT (81) This drawing is from a book printed in 1313 called (surprisingly, considering this subject: the reason being to illustrate the rotating wheel) the Treatise on Agriculture (Nung Shu). It shows a wheel-shaped rotating case for the classified storage of fonts of movable type, which were invented circa 1045 by Pi Sheng. All the characters were either carved into wooden fonts or cast into metal fonts and stored according to their rhyming spoken sounds, in twenty-four compartments, consisting of eight inner ones and sixteen outer ones. By spinning the compositor's wheel round, the pieces of type were readily accessed according to this easy system, making for speedy typesetting.

more copies were in demand. One reason for cutting down on the storage of large quantities of copies was the destruction regularly wrought by bookworms in some areas of China. It was also economically advantageous to wait for orders before buying the paper.

Korea was the first country to which printing spread from China, around the year 700. Many old printing blocks survive: at the Haein-sa Temple high on Mount Kaya in southern Korea, 81,258 blocks of magnolia carved on both sides are preserved intact today, which were used to print a Buddhist classic between the years 1237 and 1251.

Such a large number of printing blocks would not have been exceptional in China. Chinese printing was on a large enough scale to cope with the country and its population, and one individual printer in Chiangsu in the seventeenth century named Mao Chin is known to have printed 600 titles on a variety of subjects. For the Thirteen Confucian Classics he used 11,846 blocks, for the Seventeen Standard Histories he used 22,293 blocks, and for another collection he used 16,637 blocks. Even during the early stages of his career, this single private printer employed twenty block cutters and had a store of over 100,000 printing blocks. But these quantities are small compared to

those of the imperial printers, who produced several editions of the great imperial encyclopedias – over five thousand *printed volumes* each. Many of these sets still survive today.

The Chinese were also the inventors of multicolour printing. Paper money produced in the year 1107 was printed in three colours as a precaution against counterfeiting, though in this case it is possible that the two additional colours may have been stamped onto the paper. The money in question had legends in black, a circle design in vermilion, and a 'blue face' in indigo. Two-colour printing of texts seems to have begun during the next century, and an edition of the Diamond Sutra of 134() survives, which uses black for the text, and red for prayers and pictures. It became common for commentaries to appear in red beside black texts. The earliest surviving four-colour printing dates from the early twelfth century, and is in black, grey, green and red on a large single sheet discovered in 1973 in the cavity of an old pillar. It shows a

legendary figure called Tungfang Shuo, and would have been used as a wall decoration.

Chinese colour-printing techniques used watery rather than oily inks, providing subtle effects. The inks in fact exactly matched the ones used in the original artwork, and were made from the same earth pigments. When it was necessary to overlay colours, it was done in a variety of different ways. Sometimes inks were allowed to dry before having others printed over them: others were left wet. Subtle variations in pressure on different portions of the blocks resulted in gradations of printing strength, reproducing the expression and texture of brush strokes. Often the same colour would be printed over and over from the same block, with varying portions inked so that deeper tones could be obtained in selected portions of the print. Ink was also allowed to run on the block, or it was wiped away in certain places. One expert on the subject, Dr J. Tschichold, has said: 'There is hardly another graphic art in the world that depends so entirely on the artistic sympathy and understanding of the printer as does the Chinese colour print.'

A traditional Chinese form of printing which required special expertise on the part of the printer and his staff was printing by movable type. Typesetters had to be linguistic experts and scholars knowledgeable in the history of language and literature. This is because of the thousands of characters in the Chinese language, many of which are obscure and rarely used, therefore only known to learned

scholars. It is common in traditional Chinese typesetting to have at least twenty different pieces of type for each of the commonest characters. So the imperial printing works had to make 200,000 bronze characters in 1725, and in 1733 250,000 wooden characters were produced for another project. In the early nineteenth century, one private printer is known to have had a stock of no less than 400,000 different bronze characters. It is obvious that organizing this vast mass of material for printing purposes was a major problem in contrast to the ease with which movable type was used to print in the alphabets of Western languages. This was a major reason for the rare use of movable type in China, despite the fact that it was invented there four centuries before its 'invention' in Europe by Johannes Gutenberg.

Effective movable type was invented between the years 1041 and 1048 by an obscure commoner named Pi Sheng, who lived from about 990 to 1051. In his *Dream Pool Essays* of 1086, the famous scientist Shen Kua recorded the invention as follows:

During the reign of Ch'ing-li, Pi Sheng, a man of unofficial position, made movable type. His method was as follows: he took sticky clay and cut in it characters as thin as the edge of a coin. Each character formed, as it were, a single type. He baked them in the fire to make them hard. He had previously prepared an iron plate and he had covered his plate with a

LEFT (82) A modern reproduction of the movable type invented by Pi Sheng between 1041 and 1048, and a page printed from it. Movable type was not invented by Johannes Gutenberg, as is universally believed in the West. The reproduction was made from the detailed description by Shen Kua which survives from 1086.

blocks during the act of printing, as may be seen dramatically in the gradations of pink in the blossoms, thenselves made possible only because inks of a watery rather than oily nature were used. Although the pages of this book are flat, the decorated letter paper produced at the same studio in 1644 by Hu and his colleague Tsao Sung-hsüelt gave yet another dimension to the colour printing by combining it with special hand-embossing that enhanced the colour pressure variations even further, creating a subtle varying depth in three-dimensions. The Ten Bamboo Studio team achieved such spectacular printing effects that they have still not been rivalled even today, as the subtle skills of variable hand-pressure on wooden printing blocks are now a completely lost art. (Chinese Department, British Library.)

mixture of pine resin, wax, and paper ashes. When he wished to print, he took an iron frame and set it on the iron plate. In this he placed the types, set close together. When the frame was full, the whole made one solid block of type....

If one were to print only two or three copies, this method would be neither simple nor easy. But for printing hundreds of thousands of copies, it was marvellously quick.... For each character there were several types, and for certain common characters there were twenty or more types each, in order to be prepared for the repetition of characters on the same page. When the characters were not in use, he had them arranged with paper labels, one label for words of each rhyme-group, and kept them in wooden cases. If any rare character appeared that had not been prepared in advance, it was cut as needed and baked with a fire of straw. In a moment it was finished....

When Pi Sheng died, his font of type passed into the possession of my nephews, and up to this time it has been kept as a precious possession.

Earthenware types of the nineteenth century survive in China, but it became more common to use wood, enamelware, or metal in later times. The use of wooden type was perfected two-and-a-half centuries after Pi Sheng by Wang Chen, which he did, intending to use it to print his classic, the *Treatise on Agriculture*, in 1313. The wooden type was made in the years 1297 and 1298, and Wang Chen has left an account of the process.

More noteworthy than perfecting wooden type were Wang Chen's storage and handling arrangements. The type was stored in revolving tables 7 feet in diameter, supported by central legs 3 feet high. Ingenious sorting and classifying schemes were used to enable workers to find the necessary characters quickly. In the end, the *Treatise on Agriculture* was printed with bronze characters. But Wang Chen's 60,000 wooden type characters were used to print the local book, *Gazetteer of Ching-Te County*. One hundred copies of it were printed in less than a month in the year 1298.

Movable type continued to be used sporadically throughout Chinese history. It was revived under the Mongols, when a councillor of Kublai Khan decided to use the 'movable type of Shen Kua' to print books of philosophy. A nineteenth-century teacher named Chai Chin-Sheng, born in 1784, spent thirty years making a font of earthenware type, using everyone in his family to help him. By 1844 he had finally made over 100,000 sets in five sizes, which he used to print his own collected poems under the title *First Experimental Edition with Earthenware Type*. He is the earliest and perhaps the only author-printer known in China.

Movable wooden type dating from about the year 1300 survives from Eastern Turkestan in the region known as Turfan, where it was introduced by the Chinese after the Mongol conquest. Movable type was much easier to use for the Uigur scripts of Turfan than for the Chinese language. Printing is thought to have spread to Europe through Turfan, and then through Persia, which the Mongols also conquered. Paper money was printed following the Chinese system in Tabriz in Persia in 1294. It was even called by the Chinese name, *ch'ao*, which then entered the Persian language. Fifty printed pieces of Islamic material printed according to the Chinese method were excavated in Egypt in the nineteenth

century; they cannot be precisely dated, but were printed sometime between 900 and 1350. Generally speaking, however, printing was frowned upon by the Muslims.

The Mongol armies pressed ever further westwards, overrunning Russia in 1240, Poland in 1259, and Hungary in 1283. They reached the borders of Germany not long before printing made its appearance in that country - block printing appeared suddenly in Europe early in the fourteenth century. Although no hard evidence exists for its transmission from China. circumstantial evidence is strong enough to support it. In 1458, Johannes Gutenberg 'invented' movable type. But as Juan Gonzalez de Mendoza said in 1585 in his book, The History of the Great and Mighty Kingdom of China and Situation Thereof, speaking of Gutenberg's 'invention' in 'Almaine' (Germany) the century before:

But the Chinos doo afffirme, that the first beginning [of printing] was in their countrie, and the inventiour was a man whome they reverence for a saint: whereby it is evident that manie years after that they had the use thereof, it was brought into Almaine by the way of Ruscia and Moscouia [Russia and Moscow], from whence, as it is certaine, they may come by lande, and that some merchants that came from Arabia Felix, might bring some books, from whence this John Cutembergo [Johannes Gutenberg], whom the histories dooth make author [inventor], had his first foundation [got the idea].

#### PLAYING-CARDS

NINTH CENTURY AD

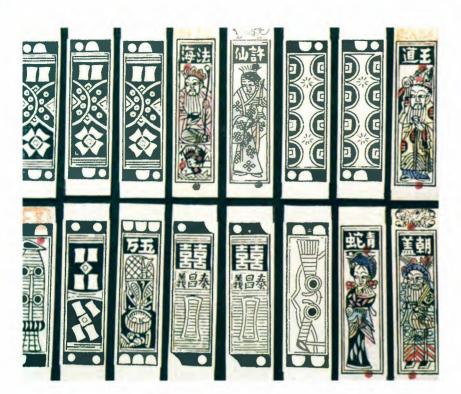

Paper was invented in China, and it is therefore not surprising that the Chinese were the first to invent paper playing-cards. By the ninth century at the latest these were in use. The first known book on card games was written by a woman in the ninth

century, but it is lost. The scholar

Ouyang Hsiu (1007-72) recorded that the use of paper playing-cards arose in connection with the change of book format from paper rolls to paper sheets and pages. The playingcards were printed by woodcut blocks, and many specimens survive. They were often coloured by hand, and popular designs for the backs were drawn by famous artists of fictional characters from the wellknown novel The Water Margin. The shape of the cards was generally more elongated than those we use today, being about 2 inches high and only about 1 inch wide. They were

LEFT (84) A Chinese playing-card of about 1400 found near Turfan, photographed before the Second World War at the Museum für Völkerkunde, Berlin, but lost during the war.

LEFT (85) Chinese playing cards were traditionally longer and narrower than European ones. These stencilled cards date from about 1870. The human figures on some of the cards are characters from the famous Ming Dynasty popular novel *The Water Margin* (also called *Outlans of the Marsh*, or in Pearl Buck's translation, *All Men Are Brothers*), which was set in the early twelfth century and is greatly beloved by all Chinese. (National Museum of Playing Cards, Turnhout, Belgium.)

of fairly thick paper, which made them more durable than those of today, though doubtless they were more difficult to shuffle.

The Chinese enthusiastically proclaimed the advantages of playing-cards over all other pastimes, pointing out that they were 'convenient to carry, could stimulate thinking and could be played by a group of four without annoying conversation, and without the difficulties which accompanied playing chess or meditation'. Furthermore, cards 'could be played in almost any circumstances without restriction of time, place, weather, or qualification of partners'. But the Chinese passion for gambling led to the promulgation during the eighteenth century of laws against gambling by officials, and against the manufacture and sale of more than one thousand paper playing-cards by a single person.

Playing-cards spread to the West from China either through the Arabs or through the travellers such as Marco Polo who circulated during the Mongol Dynasty, when there was such freedom of travel between Europe and Asia. In the seventeenth century, Valère Zani claimed that Venice was the first European city to have playing-cards from China. This may well have been the case, but the earliest appearance of playing-cards in Europe of which we can be certain was in Germany and Spain by the year 1377. By 1379,

we know they were being used in Italy and Belgium, and by 1381 in France.

Even Johannes Gutenberg, renowned as the fifteenth-century European inventor of printing by movable type (but see page 127), was involved in playing-card manufacture. He actually developed some of the mechanical means of their production, and when his financial affairs became so desperate that he was forced to close his Mainz workshop, the figures which his artists had prepared to illustrate his famous Bible were used to print the backs of playing-cards. This extraordinary fact certainly highlights the close connection that has always existed between playing-cards and book printing.

#### PAPER MONEY

NIXTH CUXTURY AD

The Chinese invented paper money at the end of the eighth or beginning of the ninth century AD. Its original name was 'flying money' because it was so light and could blow out of one's hand. The first paper money was, strictly speaking, a draft rather than real money. A merchant could deposit his cash in the capital, receiving a paper certificate which he could then exchange for cash in the provinces. This private

merchant enterprise was quickly taken over by the government in 812. The technique was then used for the forwarding of local taxes and revenues to the capital. Paper 'exchange certificates' were also in use. These were issued by government officials in the capital and were redeemable elsewhere in commodities such as salt and tea.

Real paper money, used as a medium of exchange and backed by deposited cash, apparently came into being early in the tenth century, in the southern province of Szechuan, as a private enterprise. Early in the eleventh century the government authorized sixteen private businesses or 'banks' to issue notes of exchange; but in 1023 the government usurped this private enterprise and set up its own official agency to issue bank notes of various denominations which were backed by cash deposits. We can thus probably date the world's first governmental currency reserve bank to 1023.

The money issued by this bank had printed on it a notice to the effect that it was good for only three years,

and gave the dates. Such a time limit was to be a regular feature of Chinese paper money up until the nineteenth century. By 1107, notes were being printed with multiple blocks in no less than six colours.

The issuing of paper money by the government took on enormous proportions. By 1126, seventy million strings (each string being equal to one thousand pieces of 'cash') had been officially issued. Vast amounts of this paper money were not backed by any deposits, and a horrifying inflation occurred. Inflation may be tooked upon as a phenomenon which accompanies paper money, arising from its not being backed by anything more substantial. Other forms of 'inflation' in history should probably be differently described. Accelerating price increases before the use of paper money, such as occurred so scandalously under the Roman Empire, was often caused by debasement of the coinage. The Roman Empire is infamous for having produced fixed valuation coinage out of increasingly cheap and worthless metals.

ABOVE (86) A copper plate for printing paper money; from the Southern Sung Dynasty capital of Hangchou, and dating from between 1127 and 1279 AD. Next to it is a print made from the plate as a modern example. Paper money had been invented in China by the late eighth or early muth century; the first Western paper money was issued in 1661 in Sweden.

There was also the deleterious process known as 'clipping' whereby not only individuals but sometimes governments themselves issued and circulated coins with pieces cut off them. The real value of such clipped coins was of course diminished, though the fiction was supposed to be maintained that they were worth the same as ever. But debasements and clipping of coinage should surely be differentiated from true inflation, which resulted from the issuance of paper money and was thus 'invented' in China along with the paper money that gave rise to it.

Another problem which soon arose in China was counterfeiting. If precious metal coins are in circulation which are intrinsically worth their true value, the only kind of counterfeiting possible is with false, disguised metals. This has often been done, and was a major impetus to alchemy, and the manufacture of spurious gold and silver. But paper money invited counterfeiting by its very nature, since the essence of it is not its inherent substance but the authority on which it was issued. Paper money is a symbol. To counterfeit is therefore not to fabricate a substance but to impersonate the authority issuing it. Since anyone can print on pieces of paper, the authority must make the processes of manufacture of its paper money so intricate that they cannot be exactly reproduced. Complex manufacturing secrets were thus adopted quite early, and included multiple colourings, immensely complex designs, and a mixture of fibres in the paper. The basic material for the paper of paper money was the bark of mulberry trees, and silk was sometimes incorporated. One could hand in soiled or worn-out notes for new ones, but had to pay the small cost of the printing of the replacement.

A detailed case of a counterfeiter of 1183 survives, which tells us that he printed 2600 false notes during the six-month period before he was caught. He was a master block-cutter, and he cut a block of pearwood in direct imitation of the design on a real note. It was a three-colour process, involving sequential serial numbers in blue and seals in red. It took the counterfeiter only ten days to cut the block. But counterfeiters did not have an easy time of it when they were caught, for their crime carried the death penalty.

When the Mongols came to power in China, they issued a quaint form of paper money called 'silk notes'. The deposits behind this currency were not precious metals but bundles of silk yarn. All older money had to be cashed in and exchanged for silk

notes, and the Mongols spread this unified currency all over the Empire and even beyond it. By 1294, Chinese silk notes were being used as money as far afield as Persia. In 1965, two specimens of 'silk notes' were found by archeologists.

When Marco Polo visited China, he was so impressed by paper money that he wrote a whole chapter about it, describing everything about its manufacture and circulation. He described the manner in which it was issued:

All these pieces of paper are issued with as much solemnity and authority as if they were of pure gold or silver; and on every piece a variety of officials, whose duty it is, have to write their names, and to put their seals. And when all is duly prepared, the chief officer deputed by the Khan smears the Seal entrusted to him with vermilion, and impresses it on the paper, so that the form of the Seal remains printed upon it in red; the Money is then authentic. Anyone forging it would be punished with death.

Paper money under the later Ming Dynasty was not so effective. The Ming issued in 1375 a new note called the 'Precious Note of Great Ming'. It was issued in one denomination only throughout the two hundred years in which it was the legal tender. This was naturally very inconvenient for all commercial purposes, although copper coins were permitted to circulate, and these must have provided the small change necessary in everyday life. Through inflation, the Precious Note gradually lost its value and was replaced by silver. In the middle of the seventeenth century, the Ming tried to reinstate paper money after a lapse of about two centuries, but it was badly implemented, resulting in great inflation, and failed. Paper money on a national scale and a regular basis died out until European influence brought it back in modern times.

When the older methods of paper money issuance became known in the West, they had a profound influence on Western banking. The old Hamburg Bank and the Swedish banking system were set up on Chinese lines. Thus, some of the fundamental banking procedures of the Western world came from China directly. The first Western paper money was issued in Sweden in 1661. America followed in 1690, France in 1720, England in 1797, and Germany not until 1806.

#### 'PERMANENT' LAMPS

NINTH CENTURY AD

The Chinese developed the simple oil-and-wick lamp to its furthest possibilities. First of all, they regularly used wicks that do not burn, as described in the book *Memoirs on Neglected Matters*, written about 300 AD:

In the second year of King Chao of Yen, the sea-people brought oil in ships, having used very large kettles for extracting it, and presented it to him. Sitting in the Cloud-Piercing Pavilion he enjoyed the brilliant light of the lamps in which the dragon blubber was burnt. The light was so brilliant that it could be seen a hundred li away [somewhat more than 30 miles]; and its smoke was coloured red and purple. The country people, seeing it, said, 'What a prosperous light!', and worshipped it from afar. It was burnt with wicks of asbestos.

This was in either 598 BC or 308 BC. We cannot be sure of the date, for there were two kings of Yen named Chao. Needham comments on this passage: 'Whatever the date to which this really refers, it must surely imply that some kind of primitive sealing or whaling was going on in Han or pre-Han times, and that the oil or blubber was consumed in the courts of coastal princes with unburning wicks.' Needham has gathered much material on the history of asbestos in ancient China, and mentions that the famous general Liang Chi, who died in 159 AD, had an incombustible gown of asbestos which he used to throw on the fire at parties. The asbestos wick for lamps essentially meant a permanent wick which did not need to be replaced and would burn as long as the oil was replenished.

However, asbestos wicks were by no means the limit of ancient Chinese ingenuity with regard to the economical use of lamps. The Chinese were determined to squeeze fire out of stone and get something for nothing. Having developed the inexhaustible wick, they turned their attention to the nearest thing to inexhaustible oil. Their lamps were simple dishes or cruses full of oil with wicks sticking out of them. The Chinese noticed that the heat of the burning wicks made much of the oil evaporate before it could be productively burnt. In order to counteract this, they devised a way to cool

the lamps and thus prevent the evaporation, as we are told by the author Lu Yu, in his book *Notes from the Hall of Learned Old Age*, published about 1190 AD:

In the collected works of Sung Wen An Kung there is a poem on 'economic lamps'. One can find these things in Han-chia; they are actually made of two layers. At one side there is a small hole into which you put cold water, changing it every evening. The flame of an ordinary lamp as it burns quickly dries up the oil, but these lamps are different for they save half the oil. When Shao Chi was the Prefect at Han-chia, he sent several of them to scholars and high officials at court. According to Wen An one can also use dew. Han-chia has been producing these for more than three hundred years.

So, underneath the oil there was a reservoir, into which cold water was poured, resulting in a saving of half the oil used. Since in 1190 the lamps had been manufactured for more than three centuries, their production on a mass scale must have begun no later than the beginning of the tenth century AD and, as Needham says, perhaps early in the ninth century AD. He adds: 'It was an interesting anticipation of the water-jacketing of the chemical condenser in distillation, and of the steam and water circulatory systems of all modern technology.'

The 'economic lamps' were generally made of glazed earthenware, and several good specimens are preserved in the Chungking Museum in China. Since simple wick lamps have remained in use well into the latter half of this century in China, perhaps a reintroduction of the 'economic' water-cooled version would be useful in parts of rural China today.

#### THE SPINNING-WHEEL

ELEVENTH CENTURY AD

The homely device of the spinning-wheel, which evokes images of European cottage life and Indian rural productivity alike, had its origin in China. The earliest known European reference to a spinning-wheel is an indirect one in the statutes of a guild at Speyer, Germany, in about 1280. Needham believes spinning-wheels and other machines to do with

by Cecil Beaton during the Second World War, showing an old woman who sought refuge in the Poor People's Hostel at Changsha. Her spinning-wheel is a traditional Chinese form with a double wheel. Between the wheels is strung a car's cradle of string; the belt-drive (driving-belt) runs round the centre of the car's cradle rather than along a wheel rim.

textiles were introduced to Europe by Italians who travelled to China during the Mongol Dynasty. He points out that, 'since we find very soon afterwards at such cities as Lucca in Italy silk filatures using machinery closely similar to that of China, the presumption is that one or other of the European merchants who travelled East in those days brought back the designs in his saddle-bags.'

Spinning-wheels derived from Chinese machinery for processing silk fibres. A single continuous strand of silk runs for several hundred yards and has a tensile strength of 65,000 pounds per square inch. This is stronger than any other plant fibre known, and approaches the strength of some engineering materials. The domestication of the silkworm and the development of the silk industry in China had taken place by the fourteenth century BC at the latest. Although it was apparently many centuries after this that they were developed, the silk industry obviously had a need from the beginning for silk-winding machines to deal with these enormously long fibres. Such machines are mentioned in the *Analytical* 

Dictionary of Characters of 121 AD, and again in the Eulargement of the Literary Expositor of 230 AD. These are first depicted in print in the books Pictures of Tilling and Weaving, published in 1237.

Quilling-machines of this sort for winding silk onto bobbins also made their way to Europe, and seem to have preceded spinning-wheels slightly. The textile-wheels depicted in windows of Chartres Cathedral and datable to between 1240 and 1245 are quilling-machines, and a clearer illustration of one may be seen in the Ypres *Book of Trades*, dated about 1310.

Quilling-machines go back at least to the first century BC in China. It is not clear how soon spinning-wheels derived from them, and if we wished to be conservative we could say that they did so by the eleventh century. Cotton culture had spread across China, and spinning-wheels were evidently derived from the silk-winders to deal with it. The use of the driving-belt to cause spindles to turn at great speed by connecting them with large wheels was most ingenious. The Chinese invention of the belt-drive, or driving-belt, is discussed on page 59.

#### CIRCULATION OF THE BLOOD

SECOND CENTURY BO

Most people believe that the circulation of the blood in the body was discovered by William Harvey, and that it was he who first brought the idea to the attention of the world when he published his discovery in 1628. Harvey was, however, not even the first European to recognize the concept, and the Chinese had made the discovery two thousand years before.

In Europe, Harvey was anticipated by Michael Servetus (1546), Realdo Colombo (1559), Andrea Cesalpino (1571) and Giordano Bruno (1590). These men had read of the circulation of the blood in the writings of an Arab of Damascus, al-Naf'īs (died 1288), who himself seems to have obtained the idea from China. The writings of al-Naf'īs translated into Latin were lost, and rediscovered by a scholar as recently as 1956, establishing the source for Europe.

In China, indisputable and voluminous textual evidence exists to prove that the circulation of the blood was an established doctrine by the second century BC at the latest. For the idea to have become elaborated by this time, however, into the full and complex doctrine that appears in *The Yellow Emperor's Manual of Corporeal Medicine* (China's equivalent of the Hippocratic writings of Greece), the original notion must have appeared a very long time previously. It is safe to say that the idea occurred in China about two thousand years before it found acceptance in the West.

The ancient Chinese conceived of two separate circulations of fluids in the body. Blood, pumped by the heart, flowed through the arteries, veins and capillaries. *Ch'i*, an ethereal, rarefied form of energy, was pumped by the lungs to circulate through the body in invisible tracts. The concept of this dual circulation of fluids was central to the practice of acupuncture.

The Chinese traditionally identified twenty-eight different types of pulse, which they recognized as emanating from the pumping heart. The entire view of the body and its functioning was that of a dual circulation theory of blood (which was yin) and ch'i (which was yang). The two were interrelated. As a text dating from about the time of Christ says: 'The flow of the blood is maintained by the ch'i, and the motion of the ch'i depends on the blood; thus coursing in mutual reliance they move around.' The Yellow Emperar's Manual says: 'The function of the tract-channel system of the human body is to promote a normal passage [circulation] of the blood and the ch'i, so that the vital essentials derived from man's food can nourish the yin and yang viscera, sustain the muscles, sinews and bones, and lubricate the joints.'

The Manual also says: 'What we call the vascular system is like dykes and retaining walls forming a circle of tunnels which control the path that is traversed by blood so that it cannot escape or find anywhere to leak away.' The Chinese, always so methodical at measuring and weighing things, carried out investigations in which they removed the blood vessels from corpses, stretched them to their full

OPPOSITE (88) The internal organs, featuring the heart at the centre from which the blood flows. This is a detail from a large nineteenth-century medical poster printed on rice paper, but the original drawing from which it derives was printed near the end of the Ming Dynasty in 1624, in *The Classics Classified: A System of Medicine (Lei Ching*) of Chang Chieh-Pin, to show 'the twelve viscera', However, this later version is expanded and contains considerably more anatomical (or imagined) detail than the original. (Collection of Robert Temple.)

ABOVE (89) The frontispiece to the manuscript of Andreas Cleyer's book of 1682 about Chinese pulse lore, *Specimen Medicinae Sinicae*. The Chinese doctor is taking the patient's pulse while his boy assistant stands ready with acupuncture needles, drugs and 'moxa' (powdered mugwort tinder, used for burning at selected acupuncture points). A portable stove stands in the foreground ready for use, possibly to sterilize the acupuncture needles (steam sterilization was traditional in China for several centuries). Cleyer was editor, not author, of this book, which included Latin translations of old Chinese medical texts mentioning the circulation of the blood. (Staatsbibliothek Preussischer Kulturbesitz, Berlin.)

length, and made measurements of the total distance travelled by the blood in one circuit. This was estimated by these measurements to be 162 feet.

Once every 24 hours, the blood circulation and the *dh'i* circulation 'met' again in the wrist, having completed fifty blood circuits, so that the circulations coincided. The Chinese thus computed that the blood flowed 8100 feet per day. During this time, 13,500 breaths were supposed to take place; this meant that the blood flowed 6 inches for every breath. By making all these calculations, the Chinese imagined themselves to be pinning down the phenomenon quite comfortably.

The heart was clearly conceived of as pumping the blood. Indeed, Chinese doctors used in their classrooms an extraordinary system of bellows and bamboo tubes to pump liquid in demonstrations for their pupils, showing how the heart and blood circulation worked.

In the calculations of the flow of the blood in the body, each circulation was estimated as taking 28.8 minutes. We know through medical research that this is too slow by sixtyfold, the true time being only 30 seconds. William Harvey had not come to any conclusion about this, speculating that the time taken might be 'half an hour ... an hour, or even ... a day'.

The Dutch East India physician, Willem ten Rhijne, stated in his book of 1685, Mantissa Schematica de Acupunctura, that the circulation of the blood was one of the basic tenets of the whole of Chinese medicine. He wrote: 'The Chinese physicians ... perhaps devoted more effort over many centuries to learning and teaching with very great care the circulation of the blood, than have European physicians, individually or as a group. They base the foundation of their entire medicine upon the rules of this circulation, as if they were oracles of Apollo at Delphi.'

LEFT (90) The body as a mountain: a drawing of the tenth century by Chang Po-Tuan in the version of 1333 as it appeared in Ch'en Chih-Hsii's Illustrations for the Main Essentials of the Metallons Enchymoma, the Tine Gold Elixir. In this 'body-mountain', the rivers represent de'i (life-force currents) and blood flowing around the body. At the top is K'un-Lun mountain peak, representing the head and containing 'the ball of mud' (Taoist nickname for the brain). The large pagoda in the lower central portion of the 'body-mountain' is the Yellow Court, where all rivers of blood and de'i circulation meet.

In the very same year, the renowned scholar Isaac Vossius wrote that the Chinese had known of the circulation of the blood for four thousand years. As Needham says: 'He was of course taking the legendary date of the Yellow Emperor. But some 2000 years would have been right enough.' We thus see that 300 years ago, it was widely realized in Europe that the Chinese had originated the idea of the circulation of the blood. But since that time, Europeans have reverted to a state of ignorance on the subject and forgotten this entirely.

#### CIRCADIAN RHYTHMS IN THE HUMAN BODY

SECOND CENTERY BC

Even in the mid-1960s it was considered very daring for a scientist to suggest that the body contained 'biological clocks'. Doctors and zoologists put their reputations and careers at risk by holding such opinions. Now, with hundreds, or perhaps thousands, of scientists all round the world routinely studying these 'biological clocks', their existence is universally accepted.

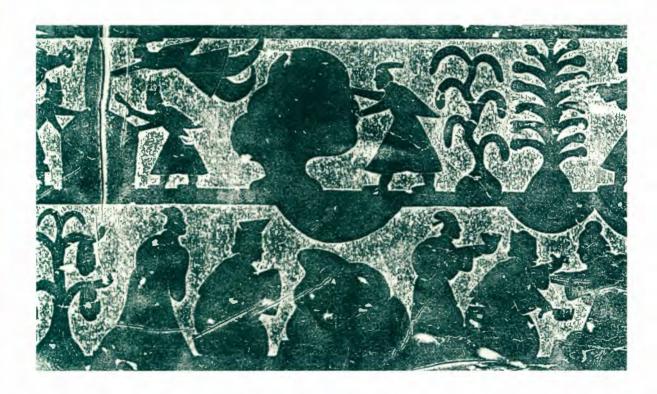

They have come to be known as 'circadian rhythms', from the Latin *circa diem*, meaning 'about a day'. Most of the internal rhythms of the body – many of which concern hormone secretions – are on an

approximately 24-hour 'clock'. The pineal gland in the head is suspected of being the actual main body 'clock'. Experiments have been carried out at the University of Texas in which the pineal glands of chickens were kept alive in test tubes and continued to act as 'biological clocks' for four days entirely on their own, without being connected to the rest of the body.

The menstrual and ovulation periods of women are possibly the most obvious of the body's longer internal rhythms. But 2200 years before European and American scientists risked being considered cranks for suggesting the existence of the 24-hour rhythms in human beings, the Chinese had observed and accepted them.

In the classic ancient medical text, *The Yellow Emperor's Manual of Corporeal Medicine*, from the second century BC, appears the following passage:

BELOW (91) A rubbing from the tomb of the Wu family in Shanting Province, showing two trees representing biological rhythms. One tree grows a leaf each day for a week and then loses a leaf a day for the next week. The other grows a leaf each day for 15 days and then loses a leaf a day for the next 15 days, being thus a 'monthly' tree. Sensitivity to body rhythms and 'biological clocks' seems to have been a natural Chinese attitude related to their tendency to view all natural processes as being caused by 'fields' rather than by 'particles'.

ABOVE (92) A pair of tiles from the Han Dynasty (207 BC–220 AD) representing the guardian spirits of two of the divisions of the day and night. *Left: tzu*, guardian of midnight (from 11 p.m. to 1 a.m.). *Right: mao*, guardian of the period 5 to 7 a.m. The Chinese were the first to realize that the body's sensitivity to drugs and proneness to symptoms vary with the hours of the day and night. (National Museums of Scotland, Edinburgh.)

Those who have a disease of the liver are animated and quick-witted in the early morning. Their spirits are heightened in the evening and at midnight they are calm and quiet.... Those who suffer from a sick heart are animated and quick-witted at noon, around midnight their spirits are heightened, and in the early morning they are peaceful and quiet.... Those who suffer from a disease of the spleen are animated and quick-witted around sunset, their spirits are heightened around sunrise and towards

evening they become quiet and calm.... Those who suffer from a disease of the lungs are animated and quick-witted during evening, their spirits are heightened at noon and they are calm and peaceful at midnight.... Those who suffer from a disease of the kidneys are quick-witted and active at midnight, and their spirits are heightened during the entire days of the last months of Spring, Summer, Autumn, and Winter, and they become calm and quiet toward sunset.

Modern medical practice has shown that there are indeed quite drastic variations in the severity of diseases and symptoms at different times of the day. For instance, it has been found that between 9 p.m. and midnight, the disabling symptoms of Parkinson's disease frequently disappear altogether. The worst paroxysms of asthma generally occur during the night, when the secretion of the hormones from the cortexes of the adrenal glands drops to its minimum. Sensitivity to histamines is greatest at 11 p.m., when the body levels of certain cortico-steroid hormones are at their lowest. The affliction of cholecystitis (inflammation of the gall bladder) is always worst in the early hours of the morning. Fevers and body temperatures increase toward evening, and our sensitivity to pain varies considerably at different times of day and night. These are all phenomena resulting from the body's internal circadian rhythms.

Acupuncture, which is thought to go back to 1500 BC in China, was practised with circadian rhythms in mind. Hence the name of one medieval acupuncture manual, Noon and Midnight Manual. Another work on acupuncture was entitled Mnemonic Rhyme to Aid in the Selection of Acu-points According to the Dinrual Cycle, the Day of the Month and the Season of the Year. The diurnal cycle refers to the daily rhythms. This work is said to have been written about 419 AD, though it may date from 930 AD.

There were many other cycles besides the circadian rhythms noted by the Chinese doctors. Some were sensible, others nonsensical. Today, through modern medicine, we know that duodenal ulcers have cycles of 139 days, that Hodgkin's disease has a cycle of 21 days, and so on. The Chinese practitioners seem to have noticed some of these things; but most of their cyclic lore was superstitious numerology. What was soundest of all was the brilliant early insight into the existence of those circadian rhythms which even today we cannot yet fully explain or understand.

#### THE SCIENCE OF ENDOCRINOLOGY

SECOND CENTURY BC

The Chinese anticipated modern biochemistry to such an extent that by the second century BC they were isolating sex and pituitary hormones from human urine and using them for medicinal purposes. The crystals which they obtained were traditionally called 'autumn mineral', being likened to the hoar-frost of the autumn. The Prince of Huai-Nan seems to have coined this term some time before 125 BC 'to express its white colour and its solidity'. This prince was one of the foremost proto-scientists of early China, who had a school of Taoist adepts and philosophers where experiments on many physical processes were carried out.

Opposition to experimentation and study by the Taoists was voiced in 25 BC by KuYung, a high official whose speech against all magicians and alchemists is preserved in the official history of the time. He makes the following attack:

The Taoists say that by fusing cinnabar they can transform it and make yellow gold, and that from dark and muddy [that is, concentrated] urine they can made a hard white ice-like [crystalline] substance.

LEFT (93) A painting from Essentials of the Pharmacopocia Ranked According to Nature and Efficacy: Imperially Commissioned, of the year 1505, edited by Liu Wen-T'ai for private deposit in the Imperial Library and not intended for publication. We see here the process of sublimation of caloniel (mercurous chloride). The figure on the left gently brushes the crystals from the sublimation lid with a feather. This same process was used for collection of pure crystals of human sex and pituitary hormones from human urine by the second century BC. From 150 gallons of human urine, 2 to 3 ounces of hormone crystals could be produced by this method. (Biblioteca Nazionale Centrale Vittorio Emanuele II, Rome.)

The great poet Pai Chü-I (772–846 AD) wrote a poem entitled 'Thinking of Old Friendships' in which he mentioned that his friend Yuan Chen, another poet (779–831), had 'prepared the "autumn mineral" drug / yet while still young encountered sudden death.'

Several centuries later, explicit recipes for the preparation of 'autumn mineral' begin to appear in print. To our knowledge the first such recipe to be published was in the book *Valuable Tried and Tested Prescriptions*, written by Chang Sheng-Tao and published in 1025. Between 1025 and 1833, at least ten different methods of obtaining sex and pituitary hormones from urine were published in thirty-nine different books. Production of these hormones took place on an enormous scale, using hundreds of gallons of human urine for each batch, and manufacturing countless thousands of doses of the drugs for medicinal use.

It was only in 1927 that S. Ascheim and B. Zondek published the discovery in Europe that the urine of pregnant women was rich in steroid sex hormones. Subsequently, the discovery was made that urine contains androgens and oestrogens (male and female sex hormones), and pituitary hormones known as gonadotrophins, which stimulate the sex glands (gonads), in profusion. Fertility drugs given to women today to make them produce more eggs are extracted from the urine of menopausal nuns in Italy. The derivation of sex hormones from human urine is today a standard practice, and modern medicines could not do without human urine as their source.

It is therefore remarkable that the Chinese anticipated this practice by 2200 years. The oldest published recipe for these hormones, dating from 1025, says:

Collect ten tan [over 150 gallons] of male urine and set up a large evaporating pan in an empty room. Fix on top of it a deep earthenware still, luting the edges together with paper-pulp and lime so that when it has dried no steam can escape. Fill the evaporating basin 70 to 80 per cent full with urine, and heat strongly from below, setting a man to watch it. If it froths over, add small amounts of cold urine. It must not be allowed to overflow. The dry residue is jen cluing poi. Put some of this, finely powdered, into a good earthenware jar and proceed according to the method of sealing and subliming by placing the whole in a stove and heating with charcoal. About two or three ounces [of sublimate] will be obtained. Grind this to a powder, and mix

with date-flesh to make pills the size of a mung bean. For each dose take five to seven pills with warm wine or soup before breakfast.

The process commences with simple evaporation, of the kind practised on a huge scale in the industry for producing salt by the evaporation of brine (see the account of deep drilling for natural gas on page 51). This left the dried solids of the urine, which had to be further processed to rid them of the urea, salts, and so on. The Chinese then turned to the process of sublimation, which was familiar from alchemy. The simplest form of sublimation is just to invert a pot over a glowing fire. Substances are thrown onto the red hot charcoal or hot ashes and sublimed upwards where they form a coating of material on the underside of the lid. An improvement of this process is to set a removable lid into the pot, which can be taken out and the powder coating brushed off with feathers. But in the urine process just described, the sublimation is a more sophisticated type. It is noteworthy that from 150 gallons of urine only two or three ounces of the precious sublimate of hormone crystals were yielded.

The Chinese stumbled upon a discovery which Europeans made only in this century, namely that steroid hormones are stable at temperatures below their melting-points, and can be successfully sublimed at temperatures varying between 130° and 210°C. There is no decomposition of steroids up to 260°, and many of them will sublime successfully at temperatures up to 300°C. Not all the Chinese methods involved sublimation, but of those that did, the process would have taken place at temperatures carefully controlled between 120° and 300°C - the very temperatures modern scientists now know to be appropriate. By this means, the hormone substances were separated from a large amount of extraneous matter and rendered relatively pure. They would still have contained amounts of some other substances, including cyanuric acid; but this has no known effects and would simply have been neutral in the preparation. Small amounts of other matter, such as indol, skatol, mercaptans, volatile fatty acids and non-steroid phenols would have mattered little, as they are all non-toxic. The hormone crystals obtained by the Chinese would not have been pure according to our modern standards, but they were without doubt highly effective, concentrated hormone substances with pronounced biological effects on patients.

The sublimation techniques of the ancient Chinese were crucial in many, though not all, of the processes of hormone extraction from urine. In China sublimation equipment was mainly used for the extraction of mercury from the mineral cinnabar, large deposits of which occur in various parts of the country. Mercury was much used for various purposes, most importantly as the essential ingredient of many elixirs of immortality. (Since mercury is a deadly poison, this resulted in many premature deaths of those who thought they were extending their lives.) Another common use of sublimation was in the extraction of camphor from chopped-up pieces of camphor wood. Small camphor sublimatories were apparently quite common in China, and featured side-tubes which arched in such a way that the sublimatories were often called 'rainbow vessels'.

Archeologists often confuse them with lamps. A beautiful example may be seen in Plate 94 (above), of a single side-tube disguised as the arm and sleeve of a young girl. This gilt bronze object was excavated in a prince's tomb and can be dated precisely to 113 BC. Objects similar to this were used for the preparation of the sex hormones from urine.

Another astonishing technique used in extracting the hormones was the use of chemicals to precipitate the hormones out of the urine. Gypsum (calcium sulphate) was used in this way, a technique which probably was derived from the bean curd industry, as gypsum is used in its production. But the most surprising and impressive substance used to precipitate the hormones out of solution was 'the juice of soap beans'. This was an extract from a saponin-containing plant, the beans of *Gleditschia sinensis*. The saponins, or

natural soap, and also the proteins of the soap-beans, had remarkable success in precipitating the hormones out of the urine into sediment. Adolf Windaus only discovered in 1909 that such substances can be precipitated by natural soaps (in his case, one called digitonin). Once again, the Chinese anticipated a modern scientific discovery by many centuries. (The earliest published method using natural soaps in this way dates from 1110, though the technique may be centuries older than that.)

There were other methods of extracting the hormones from urine which involved neither sublimation nor forced evaporation by fires. These used natural evaporation by the heat of the sun, after the addition of distilled water (sometimes called 'autumn dew water').

A great deal of attention was paid to whether the urine came from males or females, and it was mixed in varying quantities according to which kind of hormone one wanted, so that the effect was inevitably to produce 'autumn mineral' predominantly of androgens (male hormones) in some cases and predominantly of oestrogens (female hormones) in others.

In addition to the sex hormones which were isolated, there were pituitary hormones. The pituitary gland is a tiny gland in the brain which is the master gland for the entire body. It secretes a wide variety of hormones which activate or de-activate the body's other glands. Although it is only about the size of a pea, the pituitary is the most important gland we have. Its anterior lobe secretes hormones called gonadotrophins, which stimulate the gonads (sex glands). These occur in the urine, and some of the Chinese processes would have isolated gonadotrophins as well as steroids produced by the sex glands themselves. The gonadotrophins themselves actually stimulate the production of steroids by the gonads, so that by giving patients 'autumn mineral', the ancient Chinese doctors were giving double treatment - the steroids themselves and also stimulants for the patient to produce more of his own steroids.

The Chinese were predisposed by their manner of thought and a long tradition to view the body as producing powerful biologically active materials. There was an entire branch of Chinese alchemy which was devoted exclusively to this. On the one hand, there was the wai tan school of alchemy which attempted to produce elixirs of immortality, from minerals such as cinnabar, by straightforward chemical means in the laboratory. But there was on the other hand the more

esoteric school of alchemy, the very existence of which was masked by veiled references and unknown to all but the initiated – the *nei tan* school. It pursued the achievement of immortality by transformations of bodily substances through various physiological techniques. (A simple example was the practice of refusing to spit, since saliva was considered to be a precious bodily fluid which must not be wasted.)

Prominent in *nei tan* alchemy were various peculiar sexual practices. Asceticism was never popular in China, and Taoist monks were so far from being celibate that they pursued extravagant careers of sexual intercourse as part of their devotions. Taoist nuns were anything but virgins. The *yang* and *yin* ideas in China led to a prominence of sexual activity in Chinese culture which contemporary Westerners would have found incomprehensible, having been brought up in religious traditions where sex was generally viewed as sinful.

It is important to realize the essential and central role of sex in Chinese life and culture in order to view in proper perspective the Chinese achievement in isolating and using the sex hormones and gonadstimulating pituitary hormones as medicines. Far from shunning sexual matters, the Chinese thought about sex and practised sexual activity far more than Westerners. It is doubtful whether, in the West, it would have been considered proper or even admissible to pursue the isolation of such substances from urine, even had the idea occurred to anyone. The mass-production of sex hormones in the West would at most points in history simply have been unacceptable.

How did the Chinese use these hormones? They were used to treat a wide variety of ailments relating to the sex organs. Among those conditions treated were hypogonadism, impotence, sex reversals (where males spontaneously turned into females or vice versa - a phenomenon well known in ancient China), hermaphroditism, spermatorrhea, dysmenorrhea, leucorrhea, sexual debility, and even apparently stimulating the growth of the beard (since the Chinese knew that men grew beards as a result of having testicles and ceased to do so when castrated). As for the matter of swallowing oestrogens, it is known that they tend to be rendered inactive by the liver, but the Chinese seem to have indulged in such large doses that it is thought that oral consumption of them would have been effective. Perhaps the pituitary hormones were more important than the oestrogens, since they would have stimulated the patient's own oestrogens. There are

still a number of unanswered questions about the ancient Chinese hormones. For instance, no one has yet tried to reproduce the processes of extraction described in the Chinese texts, to see just what is actually produced. It is clearly a field for experimentation and investigation in the future. But there is no doubt whatsoever that the Chinese actually founded the science of endocrinology, and are entitled to the credit for that great achievement.

#### DEFICIENCY DISEASES

THIRD CENTURY AD

By the end of the nineteenth century in the West, medical men had come to realize that many diseases, such as beriberi, scurvy and rickets, were deficiency diseases. That is, they were caused by the lack of certain items in the diet. In this century, we have identified the missing dietary constituents as vitamins.

But the Chinese were aware of deficiency diseases centuries before the West. This awareness goes back into indefinite antiquity, and seems to have been a natural attitude based on the Chinese view of balance in nature, and consequently of balance in diet. As early as the fourth century BC there were Imperial Dietitians. But textual evidence of overt awareness of deficiency diseases commences in the book, circa 200 AD, of the famous doctor Chang Chi (often called 'the Galen of China'), entitled *Systematic Treasury of Medicine*. Chang gives vivid accounts of deficiency diseases and suggests dietary treatments. Although he did not have a knowledge

of vitamins, the food he recommends would have been rich in the vitamins necessary to cure the patients. He presumably knew which foods to recommend as a result of much trial and error over the years.

The well-known literary figure Han Yü (762–824) observed in one of his essays that the disease beriberi (which is caused by deficiency of Vitamin BI) was more prevalent south of the Yangtze river than north of it. A twentieth-century study of the incidence of beriberi in China found that this was quite true. The observation of Han Yü

twelve hundred years earlier was thus verified in modern times. The normal human daily requirement of Vitamin B1 is 300 to 350 international units. North of the Yangtze the study found an average intake of 450 to 690, but south of the Yangtze it was only 250 to 322. This was because in the southern area people eat rice, which when polished and washed has no husk and hence no Vitamin B1 whereas in the northern area people eat wheat and millet, and thus consume plenty of the vitamin.

The most prominent author on the subject of dietary deficiencies and diseases was Hu Ssu-Hui, who was Imperial Dietitian between 1314 and 1330. He wrote a book called *The Principles of Correct Diet* which is the Chinese classic in this field, and is collected from previous works, many of which have since been lost. In this book, Hu describes the two types of the deficiency disease beriberi (recognized today as the 'wet' and 'dry' types), and the remedies which he proposes are essentially diets rich in Vitamin B1, as well as many other vitamins:

For the cure of 'dry' beriberi:

Cook one big carp with half a pound of small red beans, two-tenths of an ounce of ch'eng-fruit skin, two-tenths of an ounce of small dried peppers, and two-tenths of an ounce of dried grass seed. Let the patient eat it.

For the cure of 'wet' beriberi:

- a) Make a soup of rice and horsetooth vegetable, and let the patient drink it on an empty stomach early in the morning.
  - b) Cook 16 ounces of pork with one handful of onion, three dried grass seeds, pepper, fermented beans and rice (half a pound) and let the patient eat it in the morning.

LEFT (95) Deficiency diseases were recognized in China by at least the third century AD. Here we see the frontispeice to the classic discussion of the subject, Principles of Correa Diet by Hu Ssu-Hui, published in 1330. The picture shows nutrition specialists giving a consultation to a patient. The caption reads: 'Many diseases can be cured by diet alone.'

In Plate 90 (page 138) we see the frontispiece of Hu's book, published about 1330. Two dietitians are seen in conference about a patient's diet. The motto in the upper right hand corner states: 'Many diseases can be cured by diet alone.'

#### DIABETES

SEVENTH CENTURY AD

Diabetes was originally called *Isiao k'o* in China, which means 'dissolutive thirst'. This was very appropriate, because diabetics have an unnatural thirst and pass vast amounts of urine. In the *Yellow Emperor's Manual* of the second century BC, diabetes is described at length. And the book pertinently says: 'A patient suffering from this disease must have been in the habit of eating many sweet delicacies and fatty foods.' Even from this period, the Chinese showed astonishing diagnostic acumen about diabetes.

We do not know when the Chinese first noticed that diabetics had excess sugar in their urine, but this was mentioned in the seventh century AD by the physician Chen Ch'üan, who died in 642. His book, Old and New Tried and Tested Prescriptions, is apparently lost, but key passages are quoted in a later book by Wang T'ao, dating from 752 and entitled Important Medical Formulae and Prescriptions Now Revealed by the Governor of a Distant Province. Wang quotes Chen as follows:

The Old and New Tried and Tested Prescriptions says that there are three forms of diabetic affection. In the first of these the patient suffers intense thirst, drinks copiously, and excretes large amounts of urine which contains no fat but flakes looking like rolled wheat bran, and is sweet to the taste. This is diabetes (hsiao k'o ping). In the second form the patient eats a great deal but has little thirst.... In the third form there is thirst but the patient cannot drink much; the lower extremities are oedematous [swollen with excessive tissue fluids] but there is wasting of the feet, impotence and frequent urination.

The first form above is the common diabetes mellitus, and the second is the form of it where the patient eats vast quantities of food. As for the last form, this may simply refer to diabetes in obese patients, for obesity is a complicating factor for diabetics. The reference

to the feet may be an observation of the problem diabetics have with poor circulation: if the diabetes gets too serious or if the sufferer wears shoes which are too tight and indulges in the use of hot-water-bottles on his feet, he can develop complications so serious in terms of boils, inflammations and so on that these can even lead to gangrene.

Also in the seventh century, the physician and bureaucrat Li Hsüan wrote an entire monograph on diabetes, and attempted to explain the reason for the sweetness of the urine in diabetic patients. He wrote:

This disease is due to weakness of the renal and urinogenital system. In such cases the urine is always sweet. Many physicians do not recognize this symptom ... the cereal foods of the farmers are the precursors of sweetness ... the methods of making cakes and sweetmeats ... mean that they all very soon turn to sweetness.... It is the nature of the saline quality to be excreted. But since the renal and urinogenital system at the reins is weak it cannot distil the nutrient essentials, so that all is excreted as urine. Therefore the sweetness in the urine comes forth, and the latter does not acquire its normal colour.

Another seventh-century physician, Sun Ssu-Mo, wrote about the year 655 in his book *A Thousand Golden Remedies* that with diabetes, 'three things must be renounced, wine, sex, and eating salted, starchy cereal products; if this regimen can be observed, cure may follow without drugs.'

Thus, by the seventh century AD, the Chinese had published their observations on the sweetness of urine of diabetics, tried to come up with an explanation for it, and proposed a dietary regimen for control of diabetes which was not far from the modern method, of avoiding alcohol and starchy foods.

By 1189, in *Medical Discourses*, the physician Chang Kao also noted the importance of skin care in diabetics and the danger of the slightest skin lesions: 'Whether or not such patients are cured, one must be on the watch for the development of large boils and carbuncles; should these develop near the joints the prognosis is very bad. I myself witnessed my friend Shao Jen-Tao suffering from this disease for several years, and he died of the ulcers.'

It should be mentioned that many of the cases of diabetes which occurred in Chinese history, especially

of prominent people, were evidently caused by metallic poisoning. This was yet another of the dangers of taking the notorious elixirs of immortality, which tended to be full of lead, mercury, and even arsenic.

The sweetness of the urine of diabetics was also known to the Indians, though it is difficult to date the Indian texts, unlike the Chinese. The sweetness of the urine of diabetics was only discovered in Europe about 1660 by Thomas Willis, and published in 1679. In 1776, Matthew Dobson identified this sweetness with sugar, and only in 1815 was the sugar specified as glucose. In terms of their anticipation of the West, the Chinese were ahead of Europeans by over a thousand years in identifying and attempting to control diabetes, though they never connected the disease with the pancreas or had any knowledge of insulin (first isolated in 1921 in the West). It was quite an achievement for the seventh century for the Chinese to arrive at this insight: 'All those who pass urine that tastes sweet but has no fatty flakes floating on it are suffering from diabetes.'

#### USE OF THYROID HORMONE

SEVENTH CENTURY AD

Goiter is an enlargement of the thyroid gland, seen as a swelling in the neck. By the seventh century AD at the latest, the Chinese were using thyroid hormone to treat goiter. This practice may have started earlier, but in the seventh century Chinese physicians described the technique in writing. The first, Chen Ch'üan, died in 642 AD. His book, Old and New Tried and Tested Prescriptions, which some attribute to his younger brother, Chen Li-yan, gives three uses for the hormone obtained from thyroid glands of gelded rams. In one prescription, he recommends that the physician wash one hundred thyroid glands in warm water, remove the fat, dry them and chop them up. He should then mix them with jujube dates and make them into pills to be swallowed by the patient.

In another prescription, he suggests that a single thyroid gland be removed from a sheep, the fat taken off, and the gland put raw into the mouth. It should be sucked by the patient until all the juice possible has been extracted and swallowed. Then the gland itself should be eaten.

Since the goiter may on occasion be a tumour, rather than an enlargement of the thyroid gland caused by gland malfunction, it is necessary to distinguish between the two conditions. This the Chinese did at the time. A near contemporary of Chen Ch'üan, Ts'ui Chih-T'i, who flourished about 650 AD, wrote a book in which he clearly distinguished between solid neck swellings which could not be cured (tumours) and movable ones which could be cured (real goiter).

Wang Hsi used the thyroid glands of various animals, including pigs and sheep, for the treatment of goiter. His method involved air-drying the glands to

reduce them to powder, which was to be taken every night in cold wine. He mentions drying fifty pigs' thyroid glands at once for such a preparation. A contemporary of his with the same surname, Wang Ying, wrote a book in which he gave a prescription for extracting the active principles of seven pigs' thyroid glands in wine, evaporating down the result, and then taking it mixed with dew. But would thyroid hormone from animals be of use to humans? It seems so. Insulin from animals treats human diabetics today. The Great Pharmacopoeia of 1596 states that it does not matter from which animals the thyroid glands are taken, as thyroid glands have the same function in all animals. The glands of pigs, sheep, water buffalo and sika deer were all in use by that time. And despite their animal source, they appear to have been effective with people.

The transmission of the knowledge of seaweed as a treatment for goiter reached the West from China along with the knowledge of the magnetic compass, the stern-post ship's rudder, and paper-making. It is thought that this entire body of knowledge was transmitted by sea during the twelfth century AD. This use of seaweed is first mentioned in a Western source by Roger of Palermo, in his *Practica Chirurgiae* 

ABOVE (97) Sargassum seaweed. It was used to treat goiter in the first century BC, according to the ancient book Classical Pharmacopoeia of the Heavenly Husbandman. Seaweed, with its high iodine content, is very effective for goiter. Knowledge of this reached Europe in the twelfth century from China.

of 1180, who suggested the use of ashes of seaweed as a medicine for goiter.

Western understanding of goiter was about twoand-a-half millennia behind China's. About the beginning of the nineteenth century, Westerners began to realize that there were environmental causes of goiter to do with the nature of the water and the soil. Awareness of this, however, is found in a Chinese book dating from 239 BC, Master Lu's Spring and Antunian Annals, in which it is stated that 'in places where there is too much light water there is much baldness and goiter'.

It is only in 1860 that Chatin proved clearly that goiter was related to a lack of iodine in the soil and water. Iodine was discovered in the thyroid gland in 1896 by Baumann. Murray and others began to administer thyroid extract to patients in the year 1890.

#### **IMMUNOLOGY**

TENTH CENTURY AD

Traces of smallpox have been found on an Egyptian mummy of the twentieth dynasty, so the disease was with us for a long time. The disease was called smallpox in Europe to differentiate it from 'grand pox', or syphilis of the skin. The official name of the disease is *Variola*.

It was under the desperate pressure to escape from the disease that humanity was introduced to that most fundamental of medical treatments, which has saved far more millions of lives than were ever lost to smallpox: vaccination. And this breakthrough occurred in China, from where it spread to Europe and led to the modern science of immunology.

The origins of inoculation against smallpox in China are somewhat mysterious. We know that the technique originated in the southern province of Szechuan. In the south-west of that province there is a famous mountain called O-Mei Shan which is known for its connections with both Buddhism and the native Chinese religion of Taoism. The Taoist alchemists who lived as hermits in the caves of that mountain possessed the secret of smallpox inoculation

in the tenth century AD. How long before that they had it we shall never know.

The technique first came to public attention when the eldest son of the Prime Minister Wang Tan (957–1017) died of smallpox. Wang desperately wished to prevent this happening to any other members of his family, so he summoned physicians, wise men and magicians from all over the Empire to try to find some remedy. One Taoist hermit came from O-Mei Shan, described variously as a 'holy physician', a 'numinous old woman' (in which case a nun), and a 'ouija board immortal' (ouija boards, or planchettes, were widely used in China, where whole books were written through 'spirit dictation'). This monk or nun brought the technique of inoculation and introduced it to the capital.

One account describes the hermit as a 'three-white adept of the school of the ancient immortals', and we may safely assume he or she was one of the Taoist alchemists specializing in 'internal alchemy', by which the clixir of immortality was meant to be concocted not in a laboratory but inside the adept's own body. The elaborate techniques used for this led to the discovery of the sex and pituitary hormones in human urine (see page 141). Inoculation is thus

another esoteric product of the quest for immortality. And it certainly did give the gift of life to many.

Inoculation has certain dangers, as well as certain advantages, which set it apart from the later technique of vaccination. When one is inoculated, one has the live virus inserted into one's body. When the process is successful, one is certainly immune for life. But the process can simply be one of direct exposure to the disease, so that one ends up with smallpox. With vaccination, the immunity conferred is only temporary, so that vaccinations have to be given every few years as 'boosters'. This is because vaccination uses dead viruses or some other kind of denatured virus (perhaps a related one) which cannot actually give one the disease.

At first sight it looks as if inoculation against smallpox must have been madness. Were not people just being given smallpox every time? The answer is no. And here we find the subtlety of the Chinese inoculators to be truly astounding. They practised a variety of methods for the attenuation of the deadly virus, so that the chances of getting the disease were minimized and the chances of immunity were maximized.

First of all, there was a strong prohibition against taking the smallpox material from people who actually had the disease. It was recognized that this would simply transmit it. They conceived of the inoculation as a 'transplant' of poxy material imagined as being like beansprouts which were just germinating. 'To inoculate' in Chinese was called *chung tou* or *chung miao*, meaning 'to implant the germs', or 'implant the sprouts'.

The method used was to put the poxy material on a plug of cotton, which was then inserted into the nose. The pox was thus absorbed through the mucous membrane of the nose and by breathing. (The technique of scratching the skin and putting the pox on the scratch seems to have developed long afterwards, possibly in Central Asia as the technique spread westwards.)

Ideally, inoculators chose poxy material not from smallpox patients but from persons who had been inoculated themselves and had developed a few scabs. They also knew the difference between the two types of smallpox, *Variola major* and *Variola minor*, and they chose poxy material from the latter, which was a less virulent form. Indeed, the favourite source of poxy material was from the scabs of someone who had been inoculated with material from somebody who had been inoculated with material from somebody who had been inoculated.... In other words, a

several-generations attenuation of the virus through multiple inoculations.

But there were other artificial methods used to attenuate the virus even further, so that it would be safer still. Here is one account from a work on *Transplanting the Smallpox* by Chang Yen in the year 1741:

Method of storing the material. Wrap the scabs carefully in paper and put them into a small container bottle. Cork it tightly so that the activity is not dissipated. The container must not be exposed to sunlight or warmed beside a fire. It is best to carry it for some time on the person so that the scabs dry naturally and slowly. The container should be marked clearly with the date on which the contents were taken from the patient.

In winter the material has yang potency within it, so it remains active even after being kept from thirty to forty days. But in summer the yang potency will be lost in approximately twenty days. The best material is that which had not been left too long, for when the yang potency is abundant it will give a 'take' with nine persons out of ten; but as it gets older it gradually loses its activity, giving perhaps a 'take' with only five out of ten people - and finally it becomes completely inactive, and will not work at all. In situations where new scabs are rare and the requirement is great, it is possible to mix new scabs with the more aged ones, but in this case more of the powder should be blown into the nostril when the inoculation is done.

Needham comments on this and similar passages:

Thus the general system was to keep the inoculum sample for a month or more at body temperature (37°C) or rather less. This would certainly have had the effect of heat-inactivating some 80 per cent of the living virus particles, but since their dead protein would have been present, a strong stimulus to interferon production as well as antibody formation would have been given when inoculation was done.

In other words, 80 per cent of the smallpox viruses with which the Chinese were inoculated would have been dead ones which could not have given anyone

smallpox. Instead, they would (as with vaccination) have stimulated the body to produce antibodies against smallpox, as well as the substance interferon which assists the immune system in general. So only about 20 per cent of the poxy material was 'live', and that was in as attenuated a form as it was possible to obtain, and of the *Variola minor* variety. Thus, traditional Chinese smallpox inoculation was about as safe as it could be, and every conceivable dodge was used to minimize the risk of its actually giving anyone smallpox.

LEFT (98) This watercolour of a child with smallpox is from a late seventeenth-or eighteenth-century manuscript entitled Methods of Treating Smallpox. This apparently unpublished work by an unknown author appears to have been used as a source for the book published later (in 1743), entitled Golden Mirror of Medicine. The three Chinese characters read, 'Drawing of the Four Emptinesses/Vords/Holes', and must refer to some technical medical terminology of that time, as the meaning is otherwise unclear, unless it refers to the poxes covering all four limbs. (Collection of Robert Temple.)

Inoculation against smallpox in China did not become widely known and practised until the period 1567–72, according to the author Yü T'ien-Ch'ih. Vivid descriptions of the practice are recorded by Yü Ch'ang in his book *Miscellaneous Ideas in Medicine*, of 1643.

During the seventeenth century, the practice spread to the Turkish regions, and it was there that it came to the attention of Europeans. The wife of the British Ambassador to Constantinople, Lady Mary Wortley Montagu (1689–1762), allowed her family to be 'variolated' in 1718. Four years before this, E. Timoni had published an account of the practice in the *Philosophical* 

Transactions of the Royal Society in London, and two years after that, J. Pilarini published a further account in the same source. So the process was being much discussed in London and Lady Mary must have been encouraged by that to take her bold step. By 1721, variolation (called then 'engrafting') began to be widely practised in Europe as protection against smallpox. We owe to this transmission from China the later developments of vaccinations and the science of immunology itself.

## Part 6 MATHEMATICS

#### THE DECIMAL SYSTEM

FOURTEENTH CENTURY BC

The decimal system, now fundamental to modern science, originated in China. Its use can be traced back to the fourteenth century BC, the archaic period known as the Shang Dynasty, though it evidently was used long before that.

Evidence of the use of the decimal system has also been tentatively reported from the ancient Harappan, or Indus Valley, civilization, which was situated on the border of modern India and Pakistan and existed earlier than China's Shang Dynasty. However, the lack of written records from that most ancient Indian culture may mean that we can never be certain of this, and whether it may thus have preceded the earliest use of decimals in China. We will also never know whether the system may have spread from one to the other or whether it evolved independently in both. Too little is also known about the shadowy Chinese dynasty prior to the Shang, and when it comes to that era in the whole of Asia, we are really lost in the mists of time. The only certainty which we have, therefore, is the extreme antiquity of the decimal system in China, and that it goes back to the earliest recorded period.

An example of how the ancient Chinese used the decimal system may be seen from an inscription dating from the thirteenth century BC, in which '547 days' is written 'Five hundreds plus four decades plus seven of days'.

From these early times, then, Chinese mathematics had the great advantage of using decimal place value in the expression of numbers and the carrying out of computations. One reason for this may be that the Chinese wrote in characters rather than using an alphabet. With an alphabet, which is inevitably more than just nine letters, there is the temptation, when using the letters to represent numbers, not to stop after 'nine', but to go on. But when that is done, there can be no decimal system, for it means giving 'ten' its own symbol rather than using the symbol for 'one' and moving it into a new column. 'Eleven' will also have its own symbol, so that it cannot be expressed as 'one ten and one unit', and so on. The ancient Greeks used their first letter, *alpha*, to represent 'one'; but they did not stop with 'nine', which was the letter *theta*; they continued, and for 'ten' used the letter *iota*.

In computation, the Chinese used counting rods on counting boards. To 'write' ten involved placing a single rod in the second box from the right, and leaving the first empty, to signify zero. To change the ten to eleven, a single rod was added in the first box. To 'write' 111, single rods were placed in the first, second and third boxes. Apparently from the earliest times, the decimal place system for numbers was literally a *place* system; the Chinese *placed* counting rods into actual boxes.

The fact that the decimal system existed from the very beginnings of mathematics in China gave the Chinese a substantial advantage, laying a foundation for most of the advances they later made. It was an advantage lacking in the West. The first evidence of the proper use of decimals in Europe is found in a Spanish manuscript of 976 AD, approximately 2300 years later than the earliest Chinese evidence.

OPPOSETE (99) A modern Chinese bank, where the traditional methods of computation by abacus are still used. The Chinese used decimal mathematics for at least 2300 years before the system was adopted in the West, and invented the negative numbers so dreaded on today's bank statements.

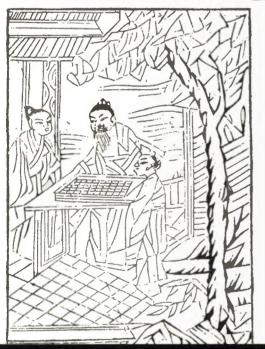

ABOVE (100) This large, sturdy nineteenth centuiry abacus, strengthened with brass fittings and made of strong teak, would have been used in a bank, large business, or official office, enduring heavy daily use as the 'office calculator'. It is can be used very rapidly (often faster than one's fingers could enter the same numbers into a modern electronic calculator), and the result can instantly be seen at a glance from the positions of the counters. (Collection of Robert Temple.)

#### A PLACE FOR ZERO

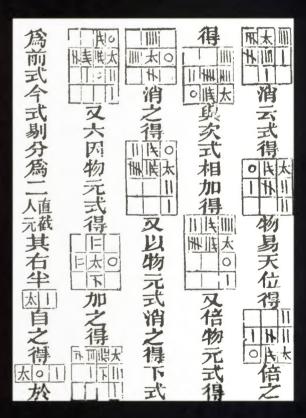

FOURTH CENTURY BO

Most of us take zero for granted. But if it were not used every day by millions of people all round the world, modern technology would collapse and be unable to function. Zero is essential to the efficient carrying out of mathematical computations. Its invention, therefore, was of the utmost importance in history. But when we speak of its invention, we may speak of two different things. First, a blank space was left for zero. This was obviously the far more important step forward. Later, an actual symbol for zero was written in the blank space. But this was largely a formality. For, once the space was there, it hardly mattered whether or not it had something written in it.

### 難問生師

ABOVE (101) Fromispiece to Ch'eng Ta-Wei's Systematic Ticatise on Aridmetic, published in 1593. The picture shows 'discussions on difficult problems between Master and Pupil', with the Master seated in front of a traditional Chinese counting-board, as described in the account of the decimal system. A natural consequence of the counting-board method was the leaving of a blank space for zero. We have evidence of this as a working concept by the fourth century BC, though it must have existed long before. The actual symbol '0' for zero is also thought to have originated in China, as a representation of the blank space.

ABOVE (102) Both zeroes and negative terms occur in this page from Chu Shih-Chich's book on algebra. Precious Mirror of the Four Elements, published in 1303. Each box, consisting of a group of squares containing signs, represents a 'matrix' form of writing an algebraic expression. The frequent occurrence of the sign '0' for zero may be clearly seen. (In these cases it means that terms corresponding for those squares do not occur in the equation.) The diagonal lines slashed through some of the numbers in the squares indicate that they are negative terms. (The number 'one' is one vertical line, the number 'two' is two vertical lines, etc.)

We know for certain that it was the Chinese who invented the use of a blank space for zero. As for the actual symbol '0', we suspect that it too first began in China, but the evidence is less clear for that. The blank space on the Chinese counting board, representing zero, dates at least as far back as the fourth century BC. Its use was perfectly simple. The number 405, for instance, would be 'written': 'four blank five', or 'four hundreds, no tens, five units'.

The traditional story for the origin of the symbol '0' for zero, as told in the West, is that it was invented in India in the ninth century AD. It may be seen in an inscription at Gwalior dated 870 AD. However, in actuality, the zero can be traced back earlier than this. It may be seen in inscriptions in Cambodia and Sumatra, both dated 683 AD, and on Bangka Island, off Sumatra, dated 686 AD. Experts believe that these inscriptions, which antedate the use of the zero in India, indicated that the zero came to India from China by way of Indo-China.

For many centuries the Chinese seem to have felt no need for an actual symbol for zero. On the counting board, the blank space was entirely adequate. It was the Chinese tradition not to include calculations in mathematical treatises, but merely to give problems and their solutions with little or no indication of the methods used; thus it was at first only in the actual recording of numbers that the need arose, and then, simply, a blank was left. When this was eventually seen to be insufficient, it is probable that the zero symbol evolved as a circle drawn round the blank space.

Absolute priority for the zero symbol is not claimed for China, since its first appearance in print is not until 1247, though there are firm grounds for believing it was used at least a century earlier. No one knows, and perhaps no one will ever know, where the actual symbol was first used, or when.

#### **NEGATIVE NUMBERS**

SECOND CENTURY BO

Westerners had a great mental struggle to accept negative numbers. These are numbers with a minus sign in front of them. To the ordinary man in the street who is not concerned with mathematics, negative numbers may still be insignificant or impossible. 'How can minus ten exist?' someone might say. 'Or if it does, it has no relation to the real world.'

But this is not true. Minus ten dollars in your bank account is real enough: you will have to pay in eleven

dollars before you have a dollar in credit. But it is better to be minus ten dollars than minus a hundred. From this example we can begin to appreciate that as soon as anything is expressed in mathematical language, negative numbers become essential for a proper description. And yet before the Renaissance, the West did not have them.

What was lacking in the West, however, was common in China. Negative numbers were recognized and used there by the second century BC. They occurred frequently on the counting board, and were represented by black rods, positive numbers being represented by red ones. Alternatively, square-sectioned rods represented negative numbers while triangular-sectioned ones represented positive numbers. If no special rods were available, a number on the counting board would be represented in a slanting position to set it apart from the positive numbers, as was done by the mathematician Liu Hui in the third century AD.

The law of signs, for plus and minus, was partially stated in a Chinese mathematical classic of the first century AD, but occurs full-blown on numerous occasions in medieval Chinese writings, stated overtly for instance in the book Introduction to Mathematical Studies of 1299. The Chinese found no difficulty in the idea of negative numbers. In this, they were seventeen hundred years ahead of the West. It was not until 630 AD that the mathematician Brahmagupta began to use negative numbers in India. In Europe, negative numbers first appear in a book by the Greek mathematician Diophantus (about 275 AD), only to be dismissed as 'absurd' when occurring as the solution of an equation. The first acceptance of negative numbers in Europe was in the mid-sixteenth century when the great Renaissance genius, Jerome Cardan (Girolamo Cardano), published his book on algebra entitled The Great Art, in 1545. In the book Cardan recognized the negative numbers he obtained in solutions of various equations, and he stated simply but clearly the laws of negative numbers. For instance, in speaking of square roots, he said 'there are two solutions, one plus and one minus, which are equal to each other'. He called a negative number debitum. But the positive numbers occurring as solutions to equations, Cardan called 'true solutions', whereas the negative ones he called 'fictitious solutions'. Therefore, though Cardan fully accepted negative numbers in mathematical operations and was prepared to treat them as normal for the sake of computation and calculation, he did not take the modern view that negative numbers can represent non-fictitious phenomena. Cardan was polite to them, but he did not take them seriously.

#### EXTRACTION OF HIGHER ROOTS AND SOLUTIONS OF HIGHER NUMERICAL EQUATIONS

FIRST CENTURY BC

David S. Smith, the great historian of mathematics, wrote in reference to the solution of higher numerical equations: 'Indeed, this is China's particular contribution to mathematics.' This is certainly true. China seems to have been the birthplace of such mathematical processes, which did not arise in Europe until the fourteenth or fifteenth century, and even then remained largely undeveloped for some time.

In the first century BC the Chinese mathematical classic *Nine Chapters on the Mathematical Art* was compiled. One of the algebraic problems given in this work is to find the cube root of the number 1,860,867. (The answer is 123.) The method used is similar to 'Horner's method', developed by W.G. Horner in 1819 in Europe.

Horner's process is a simple and elegant method of numerical calculation. It is so fundamental that it is generally used as the standard method of extraction of a square root. It is a technique of estimating a root of an equation by approximation again and again, each time more accurately than in the preceding step. Horner did this by increasing decimals, whereas earlier (in 1767) the Comte Lagrange had done it by continued fractions. Lagrange's method had been more cumbersome because the resulting fraction had to be converted to a decimal. This affords an interesting parallel to what happened in China: a 'Lagrange method' using fractions was developed there by the first century BC (nineteen hundred years ahead of Lagrange), and it was improved to a 'Horner method' in the third century AD by Liu Hui (sixteen hundred years before Horner; see page 142). Their methods were essentially specific applications of those generalized in Sturm's Theorem, which was formulated by J.C.F. Sturm in 1835, and based on their work.

Numerical equations of higher degrees than the third (that is, involving powers higher than cubes) make their appearance in print in China in the year 1245, in the *Mathematical Treatise in Nine Sections*, by Ch'in Chiu-Shao. In this work are included equations involving higher powers, such as:

$$-x^4 + 763,200x^2 - 40,642,560,000 = 0$$

It should be said that the Chinese did not write such equations in symbols, but spelled them out. They were, nevertheless, proper equations. In two books published in 1248 and 1259, *Tse Yuan Hai Ching* and *I Ku Yan Tuan*, the mathematician Li Yeh had equations like these:

$$ax^6 + bx^5 + cx^4 + dx^3 + ex^2 + fx + e = 0$$

and:

$$-ax^6 - bx^5 - cx^4 - dx^3 - ex^2 - fx - e = 0$$

As Needham says: 'Early Greek and Indian mathematics seem to have contributed little or nothing to the solution of higher numerical equations.' In the midsixteenth century, Nicolo Tartaglia and Jerome Cardan were able to solve the cubic equations. But both of them considered that equations of higher degrees were not relevant to the real world, Cardan believing that algebra was complete with the cubic equations, which related to the third dimension (than which he believed there could be none higher). Cardan's pupil Lodovico Ferrari did, however, work on equations of the fourth degree. But, by and large, Europeans were far less willing to consider higher equations in the sixteenth century than the Chinese were in the thirteenth. The first actual solutions of cubic equations in China were by Wang Hsiao-T'ung in the seventh century AD, and the first in Europe, in the thirteenth century, were by Leonardo Fibonacci, who is thought to have been influenced by Chinese sources.

#### DECIMAL FRACTIONS

FIRST CENTURY BO

It is hardly surprising that, with the decimal place system so well established in China, decimal fractions first occurred there. The earliest definite traces of them appear in connection with measurements. Decimal systems of measurement implied that when something exceeding a unit of whatever size was encountered, the fraction left over could be expressed in terms of the units smaller by a power of ten. This did not require a great mental leap, and was in fact a more or less routine matter. The system probably

RIGHT (103) Europe's least appreciated scientific genius, Simon Stevin (1548-1620). He began his career as an accountant, later becoming an engineer and mathematician and serving as Quartermaster General to the Dutch armies. Possibly influenced by Chinese sources, Stevin made innovations in the area of higher equations: he insisted on the reality of negative roots and that equations could be complete even with missing terms, and suggested that signs could be attached to numbers. He also gave rules for the solution of equations of any degree. He published the first tables of compound interest of sufficient extent to be useful to bankers and merchants, and introduced double-entry book-keeping to Holland from Italy. But the greatest triumph of his life was his introduction and defence of decimal fractions in 1585, which led to their adoption in Europe. (Artist unknown, Bibliothek der Rijksuniversiteit, Leiden.)

existed several centuries BC. A surviving inscription by Liu Hsin on a standard measure of volume can be precisely dated to the year 5 AD and speaks of a length correct to 9.5 of certain units.

The first occurrence of decimal fractions in a surviving work of mathematical literature is to be found in the writings of Liu Hui in the mid-third century AD. The fractions occur in two contexts: with measurements and in solutions to equations. In his commentary on the classic Nine Chapters on the Mathematical Art (first century BC), Liu Hui expresses a diameter of 1.355 feet. The Nine Chapters itself had spoken of extracting square roots and getting results which were not integral, that is, which left fractions. But fractions were not good enough for Liu Hui, who was, as Needham says, concerned about what he called these 'little nameless numbers', and stated that the answers should be expressed as a series of decimal places. Needham adds: 'These decimal roots were undoubtedly computed with counting rods and the results expressed in decimal fractions.'

Although developed quite clearly by the third century AD, decimal fractions were not universally adopted in China. The major obstacle to this was that the Chinese were so advanced and skilled at manipulating ordinary fractions that many of them simply did not feel the need for decimal fractions.

But decimal fractions do continually crop up in the literature. The official history of the Sui Dynasty in 635 AD expresses the value of *pi* as the decimal fraction 3.1415927, written in words. The first person

to drop the descriptive words and merely write the number as in modern decimal notation was apparently Han Yen at the end of the eighth century.

Full-blown decimal fractions applied to all operations generally, and constituting a genuine system and approach, appeared in the thirteenth century. Two of the mathematicians who were prominent in this development were Yang Hui and Ch'in Chiu-Shao. From the Chinese, the idea of the decimal fraction spread to the Arab al-Kashi who was director of the astronomical observatory at Samarkand, and who died in 1436. And, according to the historian of mathematics D.E. Smith, 'The first man who comprehended the significance of all this [in Europe] ... seems to have been Christoff Rudolff, whose Exempel-Buechlin appeared at Augsburg in 1530.' Smith adds that 'the first to show by a special treatise that he understood the significance of the decimal fraction was Stevin, who published a work upon the subject in Flemish, followed in the same year (1585) by a French translation.' Simon Stevin is known to have introduced other Chinese notions into Europe (see pages 217 and 234), so this is not surprising. But what is surprising is how late both the Arabs and the Europeans were at appreciating decimal fractions. Europe lagged behind China by over sixteen hundred years in this.

#### USING ALGEBRA IN GEOMETRY

THIRD CENTURY AD

Algebra and geometry developed independently. Today, we could not possibly do without their intimate partnership. To deprive ourselves of the use of them *together* would render modern technology impossible at once. But the connection between algebra and geometry was not always obvious. Far from it, in fact.

We now routinely use equations (algebra) to describe shapes (geometry). Everything from buildings to aeroplanes is constructed not just from blueprint drawings but from sets of equations describing the contours, surfaces, and structures. But the first people to do this sort of thing, expressing geometrical shapes by equations, were the Chinese.

A Chinese book of the third century AD called the *Sea Island Mathematical Manual* gives a series of geometrical propositions in algebraic form and describes geometrical figures by algebraic equations. Throughout Chinese history after that, if one wanted to consider geometry, algebra was regularly employed.

差 折 股弦和與勾 索之類 和如投这和而一正除得股弦較以減股弦 所得 去本自 抵 台 如 地 爲 相 弦 乘 滅 而 求股法日勾 寫 返 以 竹 句 幕 及 也 响 滅 亦 半 股 其餘 之餘為 p **改并求** 丈為 如 卽 股故 股 實倍高 祈 折者之高 命高 實變股弦 弦并之以 為 自乘為 也 句 除 此 自 較 如 折 訓 乘股 此 乘 率 相 霖 見 與 折

These techniques spread westward to the Arabs when the famous mathematician al-Khwarizmi was sent by the Caliph to be ambassador to Khazaria during the years 842 to 847. (Khazaria lay on the main trade routes between China and the West.) The first European who adopted the methods appears to have been Leonardo Fibonacci, who in his *Practica Geometriae* of 1220 used algebra in solving geometrical problems relating to the area of a triangle.

Since the Chinese for so many centuries used algebra to study geometry, why did they not go on to invent analytic geometry, which is the great expression of those principles, in which every geometrical object and every geometrical operation can be referred to the realm of numbers? It was developed in Europe by the mathematicians Pierre Fermat and René Descartes in the seventeenth century. The reason seems to have been that the Chinese, strangely enough, never made the necessary study of conic sections, which gives such basic forms as ellipses, parabolas, and hyperbolas. This was one of the Chinese blind spots. And furthermore, Needham says of the Europeans who did develop analytic geometry that they were 'reasoning from equations to geometrical figures; what the Chinese had always done was to transform geometrical figures into equations'.

It is curious that the Chinese should have been a thousand years ahead with the basic idea but that they should fail to push it home. It has often been said that the key to modern science was the applying of mathematics to every aspect of the physical world – what is called 'the mathematization of nature'. Nowhere did the Chinese come so close as in using algebra to study geometry, and perhaps nowhere was their failure to follow through more crucial in dooming them never to achieve 'modern science'.

LEFT (104) The Problem of the Broken Bamboo, from Yang Hui's book Detailed Analysis of the Mathematical Rules in the 'Nine Chapters' and Their Reclassification, published in 1261. Yang Hui was one of China's leading mathematicians, and in his works quadratic equations with negative coefficients appear for the first time. Here the broken bamboo, which forms a natural right-angled triangle, is discussed as an example of the properties of such triangles, their expression in algebra, and the use of such expressions for measuring heights and distances.

#### A REFINED VALUE OF PI

THIRD CENTURY AD

The irrational number pi can be computed to an infinite number of decimal places. It expresses the ratio of the circumference of a circle to its diameter, a relationship which cannot be framed in terms of whole numbers. (Pi is needed to compute the area of a circle or volume of a sphere.) The value of pi was computed by Archimedes to three decimal places, and by Ptolemy to four decimal places. But after that, for 1450 years, no greater accuracy was achieved in the Western world. The Chinese, however, made great strides forward in computing pi.

One way in which the ancient mathematicians tried to approach an accurate value for pi was to inscribe polygons with more and more sides to them inside circles, so that the areas of the polygons (which could be computed) would more and more closely approach the area of the circle. Thus, they could try to find a value for pi, since the circle's area was found by using the formula containing it. (They could measure the diameter, and squeeze a polygon whose area they knew into the circle; the only unknown number would be pi, which could then be calculated.) Archimedes used a 96-sided polygon, and decided that pi had a value between 3.142 and 3.140.

The Chinese tried to sneak up on pi in the same fashion, but they were better at it. Liu Hui in the third century AD started by inscribing a polygon of 192 sides in a circle, and then went on to inscribe one of 3072 sides which 'squeezed' even closer. He was thus able to calculate a value of pi of 3.14159. At this point, the Chinese overtook the Greeks.

But the real leap forward came in the fifth century AD, when truly advanced values for *pi* appeared in China. The mathematicians Tsu Ch'ung-Chih and Tsu Keng-Chih (father and son), by means of calculations which have been lost, obtained an 'accurate' value of *pi* to ten decimal places, as 3.1415929203. The circle used for the inscribing of the polygons is known to have been 10 feet across. This value for *pi* was recorded in historical records of the period, but the actual books of those mathematicians have vanished over the centuries, and the greatest loss of these is perhaps that of their book *Cluei Sluei*. Nine hundred years later, the mathematician Chao Yu-Ch'in (about 1300 AD) set himself to verify this value of *pi*. He inscribed polygons in a circle with the enormous number of 16,384 sides. By this means he confirmed the value given by the Tsu family.

The Tsu family had a lead in the computation of *pi* of about 1200 years. Even by 1600 AD in Europe, the

ABOVE (105) The first advanced knowledge of the value of *pi* originated in China, but was forgotten there in the fourteenth century. When the Jesuits went to China in the seventeenth century, the Chinese were impressed by the European knowledge of *pi*. Here we see a diagram explaining Liu Hui's exhaustion method in 264 AD for finding the value of *pi*. By inscribing 3072 sides of a polygon in a circle, Liu Hui was able to overtake the Greeks and compute the value to a fifth decimal place at 3.14159. By the fifth century, the value was computed to ten decimal places. In Europe, *pi* was only approximately calculated to seven places by the year 1600, a full twelve hundred years later.

celebrated calculation of the value of *pi* by Adriaen Anthoniszoon and his son only gave 3.1415929, an approximate value extending to seven places, which still fell three short of the value found by the Tsu family. It is not clear when a computation of *pi* in the West actually equalled that of the Tsu family. Abraham Sharp, in about 1717, found the value to 72 places, and a computation to 136 places was made by Georg Vega (1756–1802). Sometime between 1600 and 1700, Europeans appear to have equalled the precision of the Chinese of the fifth century.

Therefore, although the Greeks were the first recorded mathematicians to compute pi to four decimal places (in equivalent fractions, since they did not use decimal fractions), the first advanced computations of pi beyond that were made in China, and were not equalled in the West for about twelve hundred years.

#### 'PASCAL'S' TRIANGLE

ELEVENTH CENTURY AD

Blaise Pascal (1623–62) gave his name to a triangular array of numbers such as the one below:

1 1
1 2 1
1 3 3 1
1 4 6 4 1
1 5 10 10 5 1
1 6 15 20 15 6 1
1 7 21 35 35 21 7 1

If you study this array of numbers, you will see that every number in it is equal to the sum of the two numbers above it on either side, except for the 1's of course. Thus, 15 is the sum of the 1() above it to the left and the 5 above it to the right. And 35 is the sum of the 15 above it to the left and the 2() above it to the right.

But 'Pascal's' Triangle is not just an intriguing oddity for people who like to play around with numbers. It actually gives the numerical coefficients (the numbers which go beside algebraic letters) of the series of solutions to the raising to successive higher powers of a binomial. A binomial consists of two

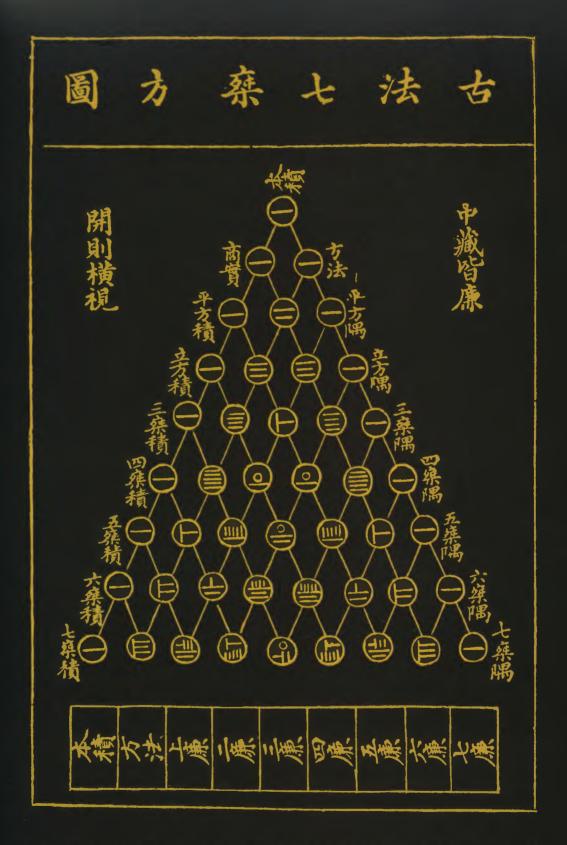

ABOVE (106) Blaise Pascal (1623–1662), French mathematician and scientist after whom 'Pascal's Triangle' is named, because he wrote about it in 1654. It was known in China more than five and a half centuries before this.

numbers added together, represented as (a + b). In the triangle, each successive line across gives the numbers which go with the solutions. Thus, if (a + b) is raised to the power of one, it stays exactly as it is, and the first line gives the coefficients of the result: 1 and 1, for a plus b. But if (a + b) is raised to the second power, meaning that it is squared, (a + b) times (a + b) gives us the answer  $a^2 + 2ab + b^2$ , and it will be immediately obvious that the numbers beside the letters of this answer are given by the second line across in the triangle, namely, 1, 2, 1. And so on as (a + b) is cubed, then raised to the fourth power, and fifth power, on indefinitely.

Now, it may seem that this too is merely an oddity. But not so. As one raises a binomial to higher and higher powers, one soon can lose one's way and wonder what the numerical coefficients are actually going to be in the solution. But a glance at an extended 'Pascal' Triangle can give the answer instantly, thus providing one with solutions to the problems without having to multiply them out. The Triangle is a wonderful time-saver, and one of the fundamental steps in getting mathematics really on its feet. But although it bears the name 'Pascal's' Triangle, it was by no means invented by Pascal. He merely put it in a newer form in the year 1654. In fact, this Triangle was invented in China. It may be seen depicted in a Chinese book of 1303 AD by Chu Shih-Chieh, entitled Precious Mirror of the Four Elements. Even here, it is called 'The Old Method'.

And old indeed it was, for it was known in China by 1100. The mathematician Chia Hsien expounded it at that time as 'the tabulation system for unlocking binomial coefficients'; but its first appearance is thought to have been in a book of that date, now lost, entitled *Piling-up Powers and Unlocking Coefficients*, by Liu Ju-Hsieh.

The mathematician and poet Omar Khayyam discussed the 'Pascal' Triangle somewhat indirectly about 1100. We do not know whether he got it from China or invented the elements of the system independently. But the first appearance of the Triangle in print in Europe was on the title page of the book on arithmetic of Petrus Apianus in 1527. Several succeeding mathematicians, such as Michael Stifel, considered it. And the Italian Nicolo Tartaglia, who was something of a scoundrel, claimed it as his own invention. But as far as we know, the inventor was indeed Liu Ju-Hsieh, 427 years before the appearance of the 'Pascal' Triangle in Europe.

ABOVE (107) 'Pascal's' Triangle was not invented by Blaise Pascal in 1654: it came from China. This diagram comes from Chu Shih-Chieh's *Precious Mirror of the Four Elements*, published in 1303. The caption refers to the triangle as the 'Old Method'; it had been expounded by the year 1100 by the mathematician Chia Hsien, who called it 'the tabulation system for unlocking binomial coefficients'

# Part 7

#### THE FIRST COMPASSES

FOURTH CENTURY BC

Needham has been able to establish that Europe acquired the compass from the Chinese. The first mention of the magnetic compass in European writings occurred in the year 1190, when, in his *De Naturis Rerum*, Alexander Neckam wrote:

The sailors, moreover, as they sail over the sea, when in cloudy weather they can no longer profit by the light of the sun, or when the world is wrapped up in the darkness of the shades of night, and they are ignorant to what point of the compass their ship's course is directed, they touch the magnet with a needle. This then whirls round in a circle until, when its motion ceases, its point looks direct to the north.

The compass does not seem to have reached Europe via the Arabs. There is no mention of the compass in Arabic writings until approximately 1232, when sailors are described as finding their way by means of a fish-shaped piece of iron rubbed with a magnet. The fish-shape was typically Chinese. The Europeans and the Arabs thus seem to have adopted the magnetic compass for sailing at roughly the same time, through nautical contact with China; but it may be that the Europeans had the compass some decades before the Arabs.

Contemporary texts support this theory. In his famous book *Dream Pool Essays*, of about 1086, the medieval Chinese scientist Shen Kua clearly wrote:

Magicians rub the point of a needle with the lodestone; then it is able to point to the south.... It may be balanced on the fingernail, or on the rim of a cup, where it can be made to turn more easily, but these supports being hard and smooth, it is liable to fall off. It is best to suspend it by a single cocoon fibre of new silk attached to the centre of the needle by a piece of wax the size of a mustard-seed – then, hanging in a windless place, it will always point to the south. Among such needles there are some which, after being rubbed, point to the north. I have needles of both kinds by me.

This was written a full century before the first mention of the magnetic compass in Europe. Needham comments:

The two needles mentioned by Shen Kua may of course have been magnetized at different poles of the lodestone ... Shen Kua's experimental conditions indicate a considerable amount of careful investigation. The

OPPOSITE (108) A Chinese mariner's compass of the nineteenth century. It has a wooden lid which fits snugly over the top to protect it, so that it can be carried in the sea captain's pocket. This was the most valuable possession of the captain of a Chinese junk, as his life depended on never losing it. The characters for north and south are here both painted red. Traditionally, south was the primary bearing, and I have a somewhat damaged sixteenth century mariner's compass where only south is painted red. By the time this compass was made, however, Western influence had become evident, and the numbers are not shown in their Chinese characters but rather as Western numerals. (Collection of Robert Temple.)

LEFT (109) A working model of the oldest instrument in the world, which is known to be a compass. The spoon or ladle is of magnetic lodestone, and the plate is of bronze. The circular centre represents Heaven, and the square plate represents Earth. The handle of the spoon points south. The spoon is a symbolic representation of the Great Bear. The plate bears Chinese characters which denote the eight main directions of north, north-east, east, etc., and symbols from the I Ching oracle books which were correlated with directions. Separately marked are the finer gradations of twenty-four compass points, and along the outermost edge are the twenty-eight lunar mansions. This type of compass has been scientifically tested and found to work tolerably well. It was used not for navigation, but for quasi-magical purposes.

use of a single thread only for the suspension would avoid twisting effects. That the thread should be of silk meant that it would be a continuous fibre, unlike a thread of hempen yarn (cotton was almost certainly not known in China in his time), in which shorter fibres would be spun together under tension. That the silk thread should be new would imply an evenly distributed elasticity.

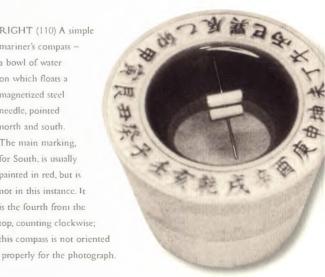

We also have an explicit account of the use of the magnetic compass for navigation, dating from before the first European mention. It is from a book by Chu Yü, son of a former high port official and then governor of Canton. The book is quaintly called P'ingchow Table Talk, and dates from 1117. Chu writes:

According to the government regulations concerning sea-going ships, the larger ones can carry several hundred men, and the smaller ones may have more than a hundred men on board.... The ship's pilots are acquainted with the configuration of the coasts; at night they steer by the stars, and in the day-time by the Sun. In dark weather they look at the south-pointing needle. They also use a line a hundred feet long with a hook at the end, which they let down to take samples of mud from the sea-bottom; by its appearance and smell they can determine their whereabouts.

The author Meng Yuan-Lao wrote in his Dreams of the Glories of the Eastern Capital about 1126: 'During dark or rainy days, and when the nights are overclouded, sailors rely on the compass. The Mate is in charge of this.' And in the book Illustrated Record of an Embassy to Korea in the Hsüan-Ho Reign-Period, from 1124, the author Hsü Ching wrote; 'During the night it is often not possible to stop because of wind or current drift, so the pilot has to steer by the stars and the Great Bear. If the night is overcast then he uses the south-pointing floating needle to determine south and north.' These references are also both prior to any Western mention of the compass.

The compass had in fact existed for centuries before this in China, but Needham has established that it was only late in its history that it came to be used for navigation at sea, the most probable period being between 850 AD and 1050. Before we discuss the history of the compass prior to its use in navigation, we should note a point of technological detail. Needham mentions that the French scholar L. de Saussure, who was himself a keen sailor:

RIGHT (110) A simple mariner's compass a bowl of water on which floats a magnetized steel needle, pointed north and south. The main marking, for South, is usually painted in red, but is not in this instance. It is the fourth from the top, counting clockwise; this compass is not oriented

RIGHT (111) A detail from a Han Dynasty stone relief of imperial magicians and conjurors dated to the year 114 AD. The seated figure is looking down at a ladle compass of the sort shown in Plate 109. (Museum Rietberg, Zurich)

...pointed out that the use of the compass in navigation depended to some extent upon metallurgical procedures for the production of steel. Soft iron does not retain its magnetism long, or show it strongly; for extended voyages magnetized needles of good steel would have been desirable. De Saussure

considered that the Chinese narratives of deepwater sailing, which we have from the thirteenth century AD, such as the embassy to Cambodia, would not have been possible without steel needles.... It may well be ... that good steel needles were available to the Chinese several centuries before Europe had them.... Failing them, lodestones had to be carried on board every ship for remagnetization, as Bromehead has described, quoting from a book on navigation of 1597. Thus for 600 years the lodestone was an economic mineral. [Magnets are remagnetized by being stroked appropriately by naturally magnetic lodestones.]

The Chinese were far advanced in their steel manufacturing capabilities (see pages 53 and 76).

The earliest and simplest form of compass was obviously a naturally magnetic piece of lodestone used to indicate direction, and this long preceded the more advanced idea of using needles. How far back did such lodestone compasses go in China, and if they were not immediately used for navigation, to what uses were they put?

We can trace the Chinese use of the lodestone compass back as far as the fourth century BC with certainty. The textual mention of it occurs in the *Book of the Devil Valley Master*, which dates from that time. The author is unknown but is thought possibly to have been the philosopher Su Ch'in. The passage says: 'When the people of Cheng go out to collect jade, they carry a south-pointer with them so as not to lose their way.' Another text from the third century BC occurs in the *Book of Master Han Fei*, written by the philosopher of that name. There, we read:

Subjects encroach upon the ruler and infringe his prerogatives like creeping dunes and piled-up slopes. This makes the prince forget his position and confuse west and east until he really does not know where he stands. So the ancient kings set up a south-pointer, in order to distinguish between the directions of dawn and sunset.

These are the two earliest known references in world literature to a compass, with the possible exception of some ancient Egyptian texts, the interpretation of which could be disputed and cannot be discussed here. In neither case is the 'south-pointer' (and it should be remarked that all Chinese compasses pointed southwards rather than northwards if possible, by preference) mentioned as something new or novel. On the contrary, it is credited to 'ancient kings' even in the third century BC.

In Plate 109 (opposite) may be seen a model of an early Chinese compass, where the pointer is in the shape of a spoon or ladle, which represents the polar constellation of the Great Bear (Big Dipper). Another early form of compass had the pointer shaped as a fish. But with the advent of steel needles, these ladles and fish were superseded, at least as far as navigation was concerned. It should be noticed, however, that far more important than the use of the compass for navigation to most Chinese was its use for geomancy. This was a magical technique for aligning houses and cities harmoniously with the breaths and currents of the Earth's forces, which were partly detected with the aid of the compass. The ladle-shaped pointer in Plate 109 is one of these geomantic compasses, and it is doubtful that it could ever have served on board a ship.

ACCELISA

We should just mention in passing that what may have been a compass dating from 1000 BC was excavated in Olmec ruins in 1967 at San Lorenzo in southern Veracruz, Mexico. If it was a compass, it is six hundred years older than the earliest Chinese evidence. Needham disputes the interpretation of the object as a compass, and we cannot enter into the controversy here.

### DIAL AND POINTER DEVICES

THIRD CENTURY AD

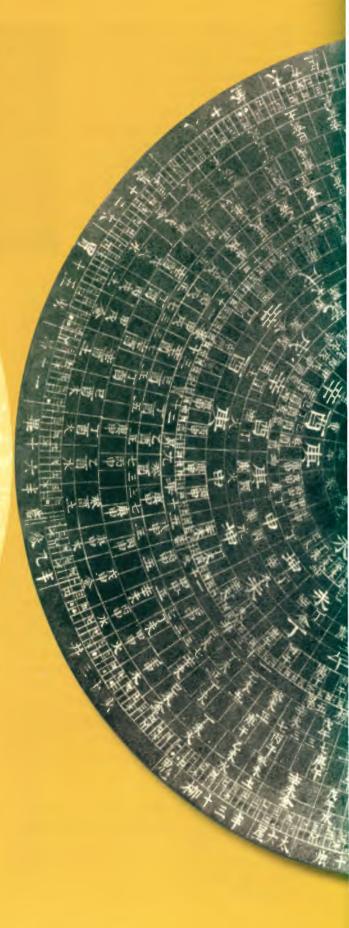

The earliest Chinese compasses did not have needles. The 'pointers' were shaped as spoons, fish, or even sometimes as turtles. The introduction of a needle was a refinement which made possible a much greater precision of readings on the dials surrounding the pointer. It was at this stage of development that we can say that the Chinese pioneered the world's first dial and pointer devices, which are absolutely fundamental to modern science.

Needham says of this development: 'Probably by the seventh or eighth century AD the needle was replacing the lodestone, and pieces of iron of other shapes, on account of the much greater precision with which its readings could be taken.'

Needles were also used as pointers on computing machines. The use of a needle in a calculating device can be traced back to at least 570 AD in China; it seems to have been a form of abacus based on compass readings. A description of it survives in a book entitled Memoir on Some Traditions of Mathematical Art, and its accompanying Commentary by Chen Luan (flourished 570 AD). Chen Luan writes: 'In this kind of computing, the digits are indicated by the pointing of the sharp end of a needle. The first digit occupies the Li position, that is, pointing full south; second, or two, is K'un, south-west; the third, or three, is at Tui, full west...'. And so on. Chen Luan adds that a digit to be multiplied is indicated by the point of the needle, whereas a digit to be divided is indicated by the needle's (differently shaped) tail.

Needham says of this:

This technique, which would seem to have been a simple sort of abacus-like device, arising out of the old diviner's board, is elsewhere attributed to, or associated with, the name of Chao Ta, a famous diviner of

the Three Kingdoms Period (221-65 AD). But the remarkable thing is that a needle is said to be used as a pointer, and the series starts from full south. It seems hard to believe that this can have had no connection with the magnetic compass, and it must be at least of 570 AD if not earlier.

Therefore, dial and pointer devices were in use in China by the sixth century AD at least, and quite possibly by the third century.

Needham rightly points out that these Chinese devices were 'the most ancient of all pointer-readings, and... the first step on the road to all dials and self-registering meters.'

The Chinese dial and pointer devices became amazingly complex. The most elaborate ones were without question the geomancers' compasses. Some of these had dials with as many as forty concentric circles containing different sets of numbers measuring different phenomena, to be read off as required. One such may be seen in Plate 112 shown here.

LEFT (112) The dial and pointer devices upon which we depend in the modern world had originated in China by the third century AD. They were geomantic compasses, used for consultation on such questions as to where a house should be built, or a city laid out. Of course, much was superstition, but at the basis of the practice was the phenomenon of the north-south alignment of the magnetized magnetic needle. The fantastic array of readings which were possible to a geomancer's compass may be seen here, though this is by no means the most complicated. Some are known with forty concentric circles of readings. The outermost circle here marks the twenty-eight lunar mansions. The next circle is marked in the 'New Degrees' of 360° adopted for the circle under Jesuit influence, indicating that this compass cannot be earlier than the seventeenth century. A full description of the readings is obviously impossible in the space available. (Science Museum, London.)

BELOW (113) A Chinese geomancer had to take special care of his geomantic compass, and I believe this may be the only old compass-carrying pouch to survive into our times. This compass is 6½ inches in diameter and dates from the eighteenth century. It fits snugly into its pouch, decorated with an embroidered *yin-yang* double-fish design and trigrams from the divination book, the *I Ching* (*Book of Change*), for luck. The pouch is fastened by three cloth buttons, so that the compass cannot slip out when travelling. (Collection of Robert Temple.)

## MAGNETIC DECLINATION OF THE EARTH'S MAGNETIC FIELD

NINTH CENTURY AD

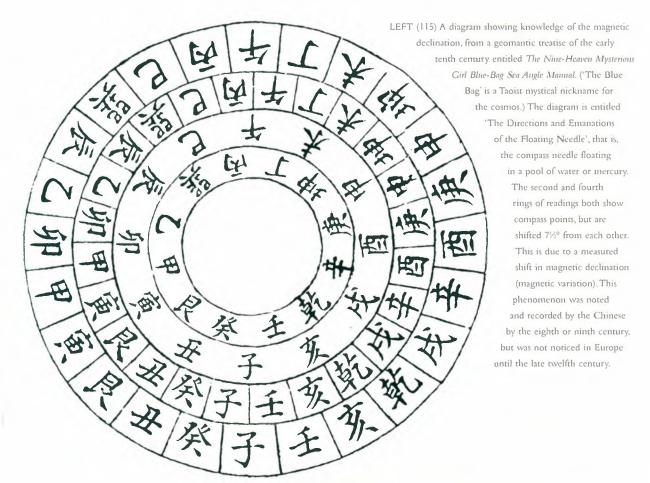

The Earth's magnetic field is oriented slightly askew from what might be expected. The magnetic North Pole is about 1200 miles from the geographical true north of the planet. The difference between a finger pointing at the true geographical North Pole and a compass needle pointing at the magnetic North Pole is known as the angle of declination (or, in the USA, variation); it is not constant, and continually shifts. By the eighth or ninth century AD at the latest, the Chinese had discovered this magnetic declination.

As Needham says, in doing so the Chinese were 'antedating European knowledge of the declination by some six centuries. The Chinese were theorizing about the declination before Europe even knew of the polarity.... The magnetic compass and the polarity of the Earth's field are not mentioned in any Western writing until 1190 AD, and the Chinese had had the compass for a good fifteen hundred years before that. In our account of the compass (page 162) we quote the medieval Chinese scientist Shen Kua, from his Dream Pool Essays of 1086. On magnetic declination he wrote: 'Magicians rub the point of a needle with the lodestone; then it is able to point to the south. But it always inclines slightly to the east, and does not point directly at the south.'

Here is another passage describing the declination, from K'ou Tsung-Shih's *Meaning of the Pharmacopoeia Elucidated*, of 1116 AD: 'When one rubs a pointed iron needle upon the lodestone proper, it acquires the property of pointing to the south, yet it inclines always towards the east, and does not point due south.'

The oldest precise and thoroughly explicit description of the declination as shown by a needle dates from about 1030–50 AD, and appears in a poem on the magnet written by Wang Chi, founder of the Fukien school of geomancers. (Fukien, as a coastal province and home of sailors, gave birth to a school of geomancy which put more emphasis on the compass than elsewhere.)

The geomancers' compasses of China (discussed under 'Dial and pointer devices' above) preserve centuries-old knowledge of two different sets of compass points showing the magnetic declination at two different times in the past. Two concentric circles of compass points were traditionally embodied in the many circles which such devices bore, showing the magnetic declination at two separate times in history.

Europeans do not seem to have known about the magnetic declination until the early fifteenth century. By 1450, German sundials were being made with a set of markings rather like those on the Chinese geomancers' compasses, indicating empirical knowledge of the declination. These date from before the voyage of Columbus to America in 1492, and show to be false the traditional story that Columbus discovered the declination when he crossed the Atlantic.

# MAGNETIC REMANENCE AND INDUCTION

ELEVENTH CENTURY AD

Just as boiled water turns to steam and undergoes a change of state, so magnets can become demagnetized by heating. There is a temperature known as the Curie point (after the famous nineteenth-century scientist) at which a magnet loses its magnetism.

But just as steam can recondense into water when it cools, so iron, after being heated to a very high

temperature, can take on magnetic properties as it cools down through the Curie point. It does this under the influence of a magnetic field in which it may happen to lie. This is described as magnetic remanence acquired through the magnetic induction of the cooling iron. Since the Earth has a faint magnetic field, usually called the geomagnetic field, a piece of cooling iron can take on a slight magnetism from the Earth's field alone, as long as the piece is oriented north-south as it cools. The Chinese were aware of this. As Needham says:

Some time before the eleventh century AD it was discovered in China that magnetization could be carried out not only by rubbing the pieces of iron on the lodestone, but by cooling them (quenching) from red heat, through the Curie point, while held in a north-south direction (the Earth's magnetic field).

Wang Ch'i wrote in his *Universal Encyclopedia* of 1609 about magnets and the destruction of magnetization by heating:

The ch'i [emanation or subtle force] and influence of the lodestone is truly as if it were living. It has a head and a tail. Its head points towards the north and its tail towards the south. The force of the head is superior to that of the tail. If it is broken into pieces, all of them also have heads and tails.... If it is heated in the fire, it 'dies' and can no longer point to the south.

But the text which explicitly describes the induction of remanent magnetism in iron is found in the Compendium of Important Military Techniques, by Tseng Kung-Liang, published in 1044. He refers to a fish-shaped magnet – which also comes into the account of the compass on page 162. The south-pointing carriage in the following account is not a magnet, but a mechanical navigation device such as has already been described (page 70). Tseng writes:

When troops encountered gloomy weather or dark nights, and the directions of space could not be distinguished, they let an old horse go on before to lead them, or else they made use of the south-pointing carriage, or the southpointing fish to identify the directions. Now the carriage method has not been handed down, but in the fish method a thin leaf of iron is cut into the shape of a fish two inches long and half an inch broad, having a pointed head and tail. This is then heated in a charcoal fire, and when it has become thoroughly red-hot, it is taken out by the head with iron tongs and placed so that its tail points due north. In this position it is quenched with water in a basin, so that its tail is submerged for several tenths of an inch. It is then kept in a tightly closed box. To use it, a small bowl filled with water is set up in a windless place, and the fish is laid as flat as possible upon the water-surface so that it floats, whereupon its head will point south.

The tightly closed box is thought to have contained a lodestone base. Needham points out that compass needles are placed in boxes with lodestone floors even today, and that a Chinese professor he knew had seen this process, called 'nourishing the needle', practised about 1950 in Anhui Province. It is sometimes necessary to 're-charge' a compass needle by contact with a lodestone. And a needle with magnetism induced by the thermo-remanence clearly described

above could be 'strengthened', or 'nourished', by the additional contact with the lodestone.

The Curie point is not an invariable temperature; it varies according to the material. It is doubtful that the Chinese could actually have measured it, therefore. They merely knew of it empirically; they had observed the results obtained by passing through it, and therefore had some conception of it through knowing the necessity for 'red heat'. Obtaining a magnet through thermo-remanence had the great advantage that a compass could be made without a lodestone. It is easy to see why this was of particular interest to those concerned with military techniques, for soldiers on campaign continually have to make shift by expedients, through lack of essential supplies. And losing one's lodestone must have been common in the heat of battle or, what is more, in retreat.

The recognition that the iron being magnetized had to be oriented to the Earth's magnetic field indicates some awareness of the existence of that field. As Needham laconically remarks: Remanent magnetism is a surprise to meet with in the early eleventh century. Thermo-remanence was of course known to William Gilbert, who illustrated the forging of a steel rod in the direction of the Earth's field.' Gilbert published his book in 1600, and in it declared the Earth to be a magnet. How much of his ideas Gilbert drew from China we do not know, but he was sufficiently aware of Chinese origins to state in De Magnete that Marco Polo had brought the magnetic compass to Europe (though, in fact, it had come earlier). And in recognizing the Chinese origin of the compass for Europe, Gilbert was better informed than many a twentieth-century scholar has been.

It must be stressed that by merely using the compass, and realizing that it pointed roughly north and south, the Chinese could have interpreted the whole process as a mere cosmic affinity. But magnetic induction by the Earth's field proved that that field was an *active force*. This was one of the greatest of scientific insights achieved by the Chinese.

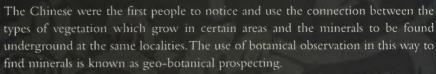

OPPOSITE (116) Artisans drawing steel wire and making steel needles to be magnetized and used for compasses. From Exploitation of the Works of Nature, published in 1637. The needles would be magnetized by thermo-remanence – heating until red-hot, aligning north—south, and quenching in a basin of water. The magnetism thus induced was discovered by the Chinese before the eleventh century; it was unknown in Europe until William Gilbert published his book De Magnete in 1600.

### GEO-BOTANICAL PROSPECTING

EIETH CENTURY BC

In modern times insufficient attention has been paid to this practice, and many of the ancient Chinese findings have not been investigated. There are, however, some widely recognized examples of plants which grow in soil too rich in certain minerals to be tolerated by other plants. There is, for instance, a wild pansy (*Viola calaminaria*) which is zinc-loving, 1 per cent of its ash constituting zinc. Even more zinc-loving is the pennycress (*Thlaspi*), 16 per cent of whose ash can constitute zinc. The tragacanth (source of gum tragacanth, once widely used in pharmacy) is quite insensitive to selenium in the soil, which poisons other plants. A particular type of alyssum (*Alyssum bertoloni*) is highly tolerant to nickel, and is a classic indicator of that metal's presence. A particular type of grass (*Panicum crusgalli*) indicates lead in the soil. There are several plants which indicate copper, and so on.

The oldest traces of this knowledge in China would seem to go back several centuries BC; but it is first found, substantiated by texts, in the third century BC. A curious ancient book called *The Classic of Mountains and Rivers*, made up of material from between 600 BC and 100 BC, mentions that the plant *hui-t'ang* grows near gold ore. This plant cannot be identified with certainty; it could be a type of orchid, basil, hawthorn, or wild pear or plum, all of which have names somewhat similar to this archaic one.

The origins of geo-botanical prospecting in China go back to the preoccupation with the nature of different types of soil and their suitability for crops. By at least the fifth century BC, geo-botany was in full swing, as testified by the treatise 'The Tribute of Yü' of that date. This text describes the natures of the soils in the different regions of China in terms which Needham has recently been able to demonstrate are technical to a degree not previously appreciated. It is therefore safe to assume that, although the primary interest was agricultural, geo-botany was beginning by that time to be used for prospecting as well. However, for the whole of Chinese history we are short of texts actually giving accounts of prospecting by these methods. Possibly the reason was secrecy. But it is also probable that such accounts as do survive still await discovery and are to be found in the thousands of old regional histories and gazetteers which have not yet been studied with any thoroughness by either Western or Chinese scholars.

The Book of Master Wen, compiled about 380 AD but containing material of the third century BC, says that in areas where jade is found, tree branches tend to droop. It is clear that the Chinese noticed not merely the occurrences of certain plants, but their physiological condition, with relation to mineral deposits. In the first half of the sixth century AD, there were at least three manuals devoted entirely to systematic accounts of geo-botanical mineral prospecting, and listing the varieties of plants and their associated

minerals. One of these, *Illustrated Mirror of the Earth*, says: 'If the stalk of [a certain] plant is yellow and elegant, copper will be found below.' It also says: 'If the leaves of [a certain] plant are green, and the stalks red, much lead will be found below.'

The early scientist and poet Chang Hua noted about 290 AD that 'where the smartweed grows abundantly, there must be plenty of haematite [ferric oxide] below.' And about 800 AD Tuan Ch'eng-Shih in his Miscellany of the Yu-Yang Mountain Cave, wrote: 'When in the mountains there is a ciboule onion, then below silver will be found. When in the mountains there is the hsiai plant [a kind of shallot], then below gold will be found. When in the mountains there is the ginger plant, then below copper and tin will be found.'

None of the above signs has ever been tested in modern times, and there is scope for research in this field. Definite awareness that mineral trace elements actually occurred in and could be extracted from certain plants is seen in the year 1421 in a book called *Precious Secrets of the Realm of the Keng and* 

Hsin (symbols of metals and minerals). There we are told quite specifically that gold occurs in the rape turnip, silver in a type of weeping willow, lead and tin in mugwort, chestnut, barley, and wheat, and copper in the Indian sorrel (Oxalis corniculata).

RIGHT (118) Round-leaved pennycress (*Thlaspi roundifolium*). Pennycress is zinc-loving, and as much as 16 per cent of its ash can constitute pure zinc. Soil rich in zinc is indicated by this plant, one of the few which can tolerate such amounts. Knowledge of plants as indicators of mineral deposits goes back many centuries BC in China, but is first documented in *The Classic of Mountains and Rivers* about the third century BC.

A later book quotes a lost work of 1062 AD called *The Illustrated Pharmacopoeia*, as saying that a particular species of purslane (still sometimes used today in the West as a herb and vegetable) contains enough mercury for the metal to be extracted from it by careful pounding, drying, and natural organic decay. The author of this lost work, Su Sung, claimed to have acquired 8 to 10 ounces of mercury in this way from 10 catties' weight of dried purslane. Mercury is a deadly poison, so purslane would appear to be dangerous to eat. The Chinese plant containing the mercury was 'green purslane' (*Portulaca oleracea*), the very same salad herb caten in the West.

European awareness of geo-botanical matters was much delayed. Needham could not find an instance before G.F. Henckel in 1760, in his book *Flora Saturnisans*. However, about 1600 there was a famous English example. About that time, Sir Thomas Challoner and his first cousin, another Thomas Challoner, discovered the first alum mines in England on the former's property of Belman Bank, Guisborough, Yorkshire. A manuscript in York

Minster informs us: 'Sir Tho. Challoner Observed the Leaves of the Oak Trees where the Mines are, to be of a deeper green than elsewhere and the Bough more spreading the Boles Dwarfish but strong having little sap, and not deep rooted ... on which he conceited there was included some valuable minerals especially Alum.' This proved to be true. Sir Thomas had visited the alum mines of Italy and noticed similar vegetation there. This appears to be the first example of geo-botanical prospecting in Europe, and is about 2100 years later than the beginnings of such methods in China.

### THE FIRST LAW OF MOTION

FOURTH CENTURY BC

Isaac Newton formulated his First Law of Motion in the eighteenth century. It stated that 'every body continues in its state of rest, or of uniform motion in a right line, unless it is compelled to change that state by forces impressed upon it.

Needham's researches have now established that this law was stated in China in the fourth or third century BC. We read in the *Mo Ching*: 'The cessation of motion is due to the opposing force... If there is no opposing force... the motion will never stop. This is as true as that an ox is not a horse.'

The book *Mo Ching* is the collection of writings of a school of philosophers called Mohists, after their founder and sage Mo Ti (more commonly known as Mo Tzu, which means 'Master Mo'). The Mohists disappeared completely from Chinese history after only a moderate time, and most of their writings remained unread and almost forgotten until recently. Their brilliant scientific insights were also largely lost, and made very little lasting impact on later Chinese history. The Mohists were also the only ancient Chinese to consider the subject of dynamics in the theoretical sense, though practical dynamics was continuously applied in the great strides made by Chinese technology and invention.

Sadly, although Newton's First Law of Motion was anticipated two thousand years earlier by the Mohists, nothing seems to have come of it. It was only in 1962 that Needham, in the first proper study of Mohist scientific doctrines, published the fact that this great step had ever been taken – but it was a step in soft sand, quickly washed away by the advancing tide of history.

# THE HEXAGONAL STRUCTURE OF SNOWFLAKES

SECOND CENTURY BC

The knowledge that snowflakes are hexagonal in shape may seem a commonplace to us today. But when the Scandinavian bishop Olaus Magnus wrote about snowflakes in 1555, he believed – despite the abundance of snow in his homeland – that they could be shaped like crescents, arrows, nails or bells, or even like the human hand. Perhaps he did see such bizarre clumps of snow, but the fact that the flakes themselves are always hexagonal eluded him. It was only in 1591 that the Elizabethan genius Thomas Hariot seems to have recognized the hexagonal nature of snowflakes, for the first time in European history. But he only jotted his findings down in his private manuscripts, and did not publish them.

The first European publication announcing the hexagonal nature of snowflakes was in 1611 (English translation first published in 1966). This was a fifteenpage account by the astronomer Johannes Kepler of his observations of snowflakes during the winter of 1610–11, entitled *A New Year's Gift, or On the Six-Cornered Snowflake*.

How impressive it is, then, to discover that the Chinese knew of the hexagonal nature of snowflakes in or before the second century BC. About the year 135 BC, Han Ying wrote a book entitled *Moral Discourses Illustrating the Han Text of the 'Book of Songs'*. In this work he incidentally referred to what appears at that time to have been common knowledge, as follows: 'Flowers of plants and trees are generally five-pointed, but those of snow, which are called *ying*, are always six-pointed.'

Thus we see that understanding of the hexagonal nature of snowflakes in China preceded such knowledge in Europe by at least 1726 years, and probably far more. Knowledge of hexagonal patterns in nature seems to have been fundamental to the earliest Chinese proto-science several centuries before the time of Han Ying. The knowledge may extend back to the earliest levels of advanced civilization in China, but Han Ying's mention is the earliest textual evidence in an explicit form connecting hexagonal patterns with snow.

Chinese literature is full of mentions of hexagonal snowflakes. For instance, the sixth-century poet Hsiao T'ung wrote in one of his poems:

The ruddy clouds float in the four quarters of the caerulean sky / And the white snowflakes show forth their six-petalled flowers.

The Chinese were traditionally keen on number mysticism. The number six was correlated with the element water. The greatest Chinese medieval philosopher, Chu Hsi, wrote in the twelfth century: 'Six generated from Earth is the perfected number of Water, so as snow is water condensed into crystal flowers, these are always six-pointed.' Even this late reference is still four-and-a-half centuries before Kepler's book on the snowflake.

The hexagonal nature of snowflakes was very much part of a Chinese cosmic scheme of nature. It was seen as an example of the most extreme form of the *yin* force of the Universe, and as a manifestation of the number associated with the element of water. It was also clearly believed that in forming snow, water condenses into the crystals. T'ang Chin, in his book *Records of My Daydreams*, spoke of water's 'congealing' into snow: 'That flowers of plants and trees are always five-pointed and snow crystals six-pointed is a saying of the old scholars, for, since six is the true number of Water, when water congeals into flowers they must be six-pointed.'

We even have textual evidence of systematic examination of snowflakes in the sixteenth century. For, about the year 1600 AD, Hsien Tsai-hang wrote in his book *Five Assorted Offering Trays*: '...every year at the end of winter and the beginning of spring I used to collect snow crystals myself and carefully examined them; all were six-pointed...'. He was probably examining his snowflakes under the magnifying power of lenses, which were in use in his day.

Although the Chinese were thus fully aware of the hexagonal structure of snowflakes, they seem never to have investigated it as a mathematical problem in the manner of Kepler. As Needham says, 'the Chinese, having found the hexagonal symmetry, were content to accept it as a fact of nature.'

OPPOSITE (119) A snowflake, photographed through a microscope. The Chinese recognized that snowflakes had six sides, or points, by the second century BC, nearly two thousand years before this was realized in Europe.

### THE SEISMOGRAPH

SECOND CENTURY AD

China has always been plagued by earthquakes. The high mountains and precipitous gorges of its crumpled, twisted surface are frequently disturbed by tremors which wreak immense havoc among the people who live there. More than 800,000 people are said to have been killed in three provinces by the great earthquake of 2 February 1556. Full records exist in the Chinese histories of all the major earthquakes over the centuries. These events were often the trigger for food riots, or attempts at rebellion. The imperial government had every reason to want to know as soon as possible when there had been an earthquake in a distant province. First of all, it would mean that grain shipments would be interrupted, which was relevant since taxes were paid in grain. But it would also mean that both food aid and extra military forces would be needed in the afflicted area without delay. Early warning was essential.

A solution was provided by the brilliant scientist, mathematician and inventor Chang Heng, who was Astronomer-Royal during the later Han Dynasty. He also wrote a number of books of which one, *Spiritual Constitution of the Universe*, survives only in fragments; but these are sufficient to show that he envisaged the Earth as a spherical ball suspended in infinite space, with nine continents. Chang Heng was the first in China to introduce the crisscrossing grid of latitudinal and longitudinal lines in geography – 'throwing a net over the Earth', as it was called.

But what amazed the court and all officialdom was Chang Heng's spectacular earthquake detector, or seismograph. 'Nothing like this had ever been heard of since the earliest records began,' was the comment of the official historian for the year 132 AD, speaking of this invention.

At first the court officials could not really believe that Chang Heng's invention could work, even though they had all inspected it and seen it demonstrated. The signal for an earthquake was the falling of a bronze ball into the open mouth of a bronze toad, from the mouth of a bronze dragon above. The official historian describes how the sceptical were converted as follows:

On one occasion one of the dragons let fall a ball from its mouth though no perceptible shock could be felt. All the scholars at the capital were astonished at this strange effect

occurring without any evidence of an earthquake to cause it. But several days later a messenger arrived bringing news of an earthquake in Lung-Hsi [Kansu, about 400 miles away to the north-west]. Upon this everyone admitted the mysterious power of the instrument. Thenceforward it became the duty of the officials of the Bureau of Astronomy and Calendar to record the directions from which earthquakes came.

What did this extraordinary machine look like, and how did it work? It consisted of a 'fine cast bronze' vessel, rather like a wine-jar, 6 feet across, with a domed lid. The outer surface of the vessel was decorated with motifs of mountains, tortoises, birds, animals and antique writing. All around the vessel was a series of eight dragons' heads, equally spaced, ABOVE (120) A modern reconstruction of Chang Heng's seismograph of 132 AD. A bronze ball falling from the mouth of a dragon into the waiting open mouth of a bronze toad made a loud noise and signaled the occurrence of an earthquake. By looking to see which ball had been released, one could determine in which direction the epicentre of the earthquake lay. (Science Museum, London.)

holding bronze balls in their mouths. The balls would drop out if the dragons' mouths opened, or if pushed.

Round the base of the vessel sat eight corresponding bronze toads, looking upwards, with their mouths wide open. They were positioned directly beneath the dragon mouths, ready to catch the falling balls. Obviously, a bronze ball dropping into a bronze toad would make a great deal of noise; people would be alerted by the resounding clang. This principle in itself is an interesting innovation, being a kind of predecessor

of the alarm clock. It may well be that Chang Heng invented the idea of the dropped ball independently, but the principle had been used earlier in the West. Needham says: 'The principle of recording by means of dropping balls was one in which Chang Heng had been anticipated by Heron of Alexandria (fl. 62 AD), who used them in some of his hodometers.' Needham was unaware, however, of an even earlier tradition in Greece, according to which the falling ball alarm device appears to be an invention of Aristotle. Towards the end of his life Aristotle suffered from either a severe gastric ulcer or stomach cancer. In order to alleviate the terrible pain he would lie in bed with a skin filled with hot oil placed on his stomach - a kind of ancient hotwater bottle. If he drifted off to sleep, though, he would be badly burned. So he devised a system whereby he held a bronze ball in his hand over a bronze bowl, so that if he dozed off he would be awakened immediately by the sound of the ball dropping into the bowl.

This may be where Heron got the idea, and it is possibly also the origin of Chang Heng's falling-ball arrangement. For this is just the sort of popular tale about a famous sage which would have circulated round the ancient world, eventually becoming part of the lore brought to China from the Near East during the three centuries before Chang Heng's time. (In the

stable period of the Han Dynasty there was considerable trade and travel between East and West.)

But how precisely were the balls released, and how could the machine be restricted to dropping only a single ball? The ancient sources are rather vague. Little is said about the workings of the dragon-mechanism: 'The toothed machinery and ingenious constructions were all hidden inside the vessel, and the cover fitted down closely all round without any crevice.'

We are also told: 'Inside there was a central column capable of lateral displacement along tracks in eight directions, and so arranged that it would operate a closing and opening mechanism.'This 'central column' was quite clearly a pendulum of some kind. It would move when there was an earth tremor and release a ball. As soon as the ball was dropped, an immobilization of the mechanism took place, preventing secondary earth tremors releasing all the balls and thus ruining the point of the device.

The account adds: 'Now although the mechanism of one dragon was released, the seven other heads did not move, and by following the azimuthal direction of the dragon which had been set in motion, one knew the direction from which the earthquake shock had come. When this was verified by the facts there was found an almost miraculous agreement.'

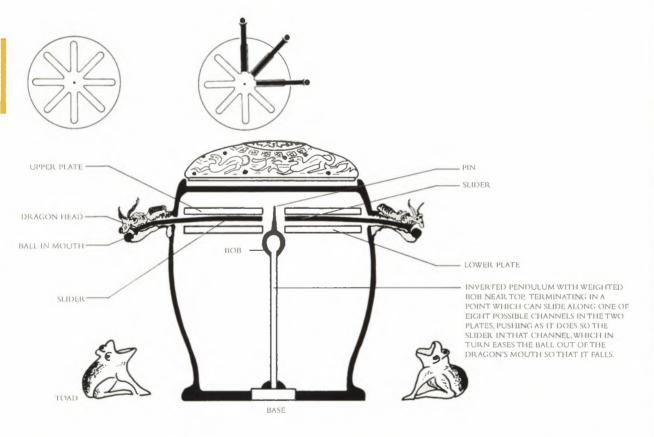

LEFT (121) A cut-away view of the modern model of Chang Heng's seismograph of 132 AD in the Science Museum, London, showing one version of the interior apparatus. In this version, designed by the Chinese scholar Wang Chen-to in 1936, the long cylindrical object in the middle is a pendulum, which is imagined as tilting slightly with an earth tremor. However, an inverted weighted bob is more likely to have been used by Chang Heng than a pendulum, and later reconstructions are closer to the surviving descriptions of how the machine actually worked.

In later centuries, similar instruments were constructed in China using the principles of Chang Heng's machine. The mathematician Hsintu Fang wrote about the machine, giving diagrams, three hundred years later, and is presumed to have made one. The same is true of Lin Hsiao-Kung, some time between 581 and 604 AD. But by the time of the Mongol rule in the thirteenth century, the principles of the seismograph had been lost. Thus did the Chinese often forget their own achievements.

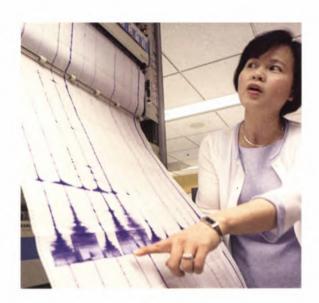

Several attempts have been made in this century to reconstruct the machine's mechanism. Japanese scientists led by Imamura Akitsune built what is probably the most accurate version at the Seismological Observatory of Tokyo University in the 1930s. It worked as an earthquake detector, but they:

...found that the ball was usually released not by the initial longitudinal wave, but by secondary transverse waves; though if the first shock was very strong, it would do.... In some circumstances one had to take the direction at right angles to the dropped ball as that of the earthquake's epicentre. Imamura points out that by estimating the direction of the preliminary tremors, and consequently the focal distance, one could give a rough estimate, not only of the direction, but also of the distance, of the earthquake.

Imamura's reconstruction may be seen in the accompanying diagrams, which have been redrawn with slight amendments by the author. An inverted pendulum with a weighted bob near the top is sensitive to earth tremors, and tilts over when it perceives one. A long sharp pin at the top moves along one of the eight channels between two plates, pushing a 'slider'. This 'slider' is in contact with the ball in the dragon's mouth at the end of the channel, and pushes the ball out of the mouth so that it drops (or alternatively, it eases the dragon's mouth open slightly, thus releasing the

ABOVE (122) The author's own reconstruction of the most likely mechanism of Chang Heng's seismograph, an improved version of Imamura Akitsune's attempt in 1939. Imamura adopted the principle of the inverted weighted bob, shown here, and the pin which entered one of eight grooves and pushed sliders, which released the balls. The top view shows the two plates from above, with three of the sliders and balls represented (the sliders would be between the plates, and hence are only shown superimposed on the lower one). The side view shows the full apparatus.

ABOVE (123) A modern Chinese seismograph in operation. The senior seismologist at Taiwan's Central Weather Bureau points out on a chart an earthquake measuring 6.2 on the Richter Scale, which struck Taipei on June 14, 2001. No one was injured.

ball). The immobilization is simply obtained because the pin is in a channel and would have to slide back first, before it could enter another channel. This version seems to offer the most likely explanation of the original mechanism.

The instruments we use today only began their development in 1848. The first modern seismograph of any kind was designed by De la Hautefeuille in 1703, making Chang Heng exactly 1571 years in advance of the West with his ingenious machine.

### SPONTANEOUS COMBUSTION

SECOND CENTURY AD

The Chinese were apparently the first people to become aware of the phenomenon of spontaneous combustion. The earliest surviving account of it in a Chinese text is found in a book which may be called either *Record of the Investigation of Things*, or *Record of Strange Things*, depending on how the title is translated. It was written before 290 AD by the statesman, philosopher and poet Chang Hua.

He collected tales of bizarre and supernatural phenomena, and studied them in a more or less scientific fashion. His biographer says of him: 'All sorts of rare books and objects whose very existence was thought to be doubtful could have been found in

Hua's household. So huge was his collection, and so wide his knowledge of the world, that his erudition was regarded as peerless in his time.'

Many of the phenomena he studied involved 'strange radiances', 'strange phenomena', 'mysterious purple vapour', 'luminous objects', 'five-coloured lights', and resonance puzzles. It is therefore hardly surprising that, with such interests, Chang Hua should have preserved the earliest account of spontaneous combustion. Here is the note he made of it, in describing an episode which took place during his own lifetime:

If ten thousand piculs of oil are accumulated in store, the oil will ignite itself spontaneously. The calamitous fire which occurred in the arsenal in the time of the Emperor Wu [of the Chin Dynasty] in the T'ai-Shih reign-period [265–74 AD] was caused by the stored oil.

It took a great deal of perspicacity to recognize and acknowledge the phenomenon of spontaneous combustion, since the more usual course, often repeated, was simply to blame arsonists. In a thirteenth-century Chinese work entitled *Parallel Cases Solved by Eminent Judges*, we have an account of how spontaneous combustion was only with difficulty accepted as the explanation for a disastrous fire, which had occurred in about 1050, and the lives of those who had been thought responsible were thereby saved:

When the Director of the Sacrifices Department of the Ministry of Rites, Ch'iang Chih, was serving as Intendant of the Imperial Guards at the palace of K'aifeng, oiled curtains had been left piled up in the open air, and one night they caught fire. According to the law the men responsible for looking after them all incurred the penalty of death. But at the preliminary hearing of the case, Ch'iang Chih conceived doubts about the cause of the fire, so he summoned the workmen who had made the curtains and questioned them. These artisans said that during the manufacture of the curtains a certain chemical was added to the oil, and that if they were left for a long time piled up, then on getting damp they might start burning. When Ch'iang Chih reported this to the Emperor Jen Tsung [reigned 1023-63] the Emperor was suddenly struck with an idea and said, 'The fire which recently occurred in the mausoleum of the Emperor Chen Tsung [died 1022] started in oil garments. So that was the cause!' The guards were let off with a lighter punishment.

The author of this refers to the previous account by Chang Hua, and adds: 'Chang Hua thought that the fire which occurred formerly during the Western Chin Dynasty in the arsenal originated from the oil which was stored there, but in fact it must have been from the same cause as mentioned here [the spontaneous ignition of oiled cloth].'

The oiled cloths in question were probably material for tents. Needham points out that the only chemical which would seem to suit the description and which could have had the effect described is quicklime, which was possibly used as a whitening agent. It is also interesting, he notes, that oil and quicklime were once thought to be the recipe for 'Greek fire', the burning liquid which the Byzantines used in warfare (and which is now known to have been petroleum).

The first Western recognition of spontaneous combustion was apparently by J.P.F. Duhamel, in a

scientific paper published (in French) in 1757. He discussed how a stack of canvas sails treated with ochre in oil and left to dry in a July sun was found to be burning at its centre within only a few hours. We now know that oiled cloths must never be stacked up and stored because they will ignite spontaneously; army and navy storekeepers, for instance, are issued with instructions never to allow this to happen. The processes of auto-oxidation, desaturation, aldehyde formation and so on can give out sufficient heat to create the ignition temperature for the surrounding oil. The cellulose fibres of the textiles provide ample wick, and the small amounts of air between the layers provide oxygen for the burning. The result is a gigantic conflagration.

### 'MODERN' GEOLOGY

SECOND CENTURY AD

James Hutton (1726–97) was the father of modern geology. In 1785 he published his *Theory of the Earth*, in which the principles of modern geology were

for the first time enunciated in the West. Because his writings were difficult, his work received little attention until a more lively summary of it was published in 1802 by his friend John Playfair, entitled *Illustrations of the Huttonian Theory of the Earth*.

It may seem strange to us now to realize that, before Hutton, Europeans did not understand what we today

LEFT (124) James Hutton, founder in the West of 'Huttonian geology', which unknown to him had been explained by the Chinese 1600 years earlier. Hutton's views were fiercely opposed by his contemporaries, and he is one of the heroes of Western science for advocating them in the face of vicious and even hysterical opposition, especially by religious fundamentalists. His views are now the basis for the whole of modern geology, and without them we would understand nothing whatever of how the earth's surface was formed.

think obvious. But it was Hutton who first put forward the idea that sedimentary rocks were laid down under ancient seas, then thrust up, buckled and twisted as mountains, by the expansive effect of subterranean heat. He suggested that intrusions of molten lava were sent shooting through the cracks in the distorted layers, giving us the igneous veins of rock. All the upraised land, he said, was then subject to erosion, and was worn away, making its way to the sea, where it was deposited on the sea bed and one day would in turn be uplifted to form mountains. This, in 1802, was considered revolutionary.

All of these ideas were common currency in China centuries before James Hutton. All of the essentials of the Huttonian system of geology were enunciated in 1086 by Shen Kua in his *Dream Pool Essays*. For instance, he speaks of erosion of mountains and says that there are certain lofty peaks which

...are precipitous, abrupt, sharp, and strange.... Considering the reasons for these shapes, I think that (for centuries) the mountain torrents have rushed down, carrying away all sand and earth, thus leaving the hard rocks standing alone.

ABOVE (125) A painting by Li Kung-Lin, c. 1100. The background is an exposed cliff of twisted rock strata, which in geology is called an 'anticlinal arch'. This one is just north of the Yangtze River between Hankow and Nanking, at Lung-Mien Shan near T'ung-ch'eng in Anhui Province. When James Hutton claimed in 1785 that the Earth's surface had been drastically buckled and twisted by volcanic forces, producing such configurations as this anticlinal arch, his theory was not believed. But the Chinese had understood its principles since the second century AD, long anticipating him in founding 'modern geology'.

He describes sedimentary deposition as follows:

When I went to Hopei on official duties I saw that in the northern cliffs of the T'ai-Hang Shan mountain range, there were belts [strata] containing whelk-like animals, oystershells and stones like the shells of birds' eggs [fossil echinoids]. So this place, though now a thousand li west of the sea, must once have been a shore. Thus what we call the 'continent' must have been made of mud and sediment which was once below the water. The Yü Mountain, where Yao killed

Kun, was according to ancient tradition, by the side of the Eastern Sea, but it is now far inland.

Now the Yellow River, the Chang Shui, the Hu T'o, the Cho Shui, and the Sang Ch'ien are all muddy, silt-bearing rivers. In the west of Shensi and Shansi the waters run through the gorges as deep as a hundred feet. Naturally mud and silt will be carried eastwards by these streams year after year, and in this way the substance of the whole continent must have been laid down. These principles must certainly be true.

Shen Kua did not originate all these ideas, but he expounded them well and combined them with his own personal observations in the field. The concept of the seabed's having been lifted up over the course of ages to become mountains went back centuries before Shen Kua's time in China. It seems to have developed under the influence of the Buddhists, who came from India. Since the Buddhists believed that the world was often destroyed and recreated, the Chinese took this notion and combined it with their observations of sea shells on mountain tops, to envisage cataclysmic geological changes. The key Chinese concept was of the sang t'ien, or 'mulberry grove'. This was the quaint phrase used to describe patches of dry land in the mountains which had once been under the sea. We find this phrase used by the alchemist Ko Hung about 320 AD in his book Lives of the Divine Hsien. (A hsien is a man who has become an immortal.) Ko Hung wrote of the legendary immortal Ma Ku, and had her say:

Since I was last invited here I have seen the Eastern Sea has turned into mulberry groves. This change has occurred three times. The last time I arrived at Mount P'eng-Lai [for an assembly of *hsien* immortals] I noticed that the sea was only half as deep as it had been at the

RIGHT (126) An aerial photograph taken in the province of Shensi, showing the drastic soil crosion in that area of loess soil. The Chinese were the first to appreciate the important part played by erosion in shaping the Earth's surface. As Shen Kua wrote in 1086: 'I think that for centuries the mountain torrents have rushed down, carrying away all sand and earth, thus leaving the hard rocks standing alone.'

previous meeting. It looks as if the sea will again be turned to mountains and dry land.

Fang P'ing laughed and said, 'The sages all maintained that where the sea is now the dust will one day be flying.'

If in 320 AD an author could say that the sages 'all maintained' this, then the tradition must be far more ancient. There is a reference to the idea in the official history of the Chin Dynasty, where Tu Yü (222–84 AD) is described:

Tu Yü often used to say that the high hills will become valleys and the deep valleys will become hills. So when he made monumental steles recording his successes he made them in duplicate. One was buried at the bottom of a mountain, and the other was placed on top. He considered that in subsequent centuries they would be likely to exchange their positions.

These concepts were a continuous part of Chinese literary, historical and philosophical tradition. The famous Neo-Confucian philosopher Chu Hsi (1130–1200 AD) wrote:

The waves roar and rock the world boundlessly, the frontiers of sea and land are always changing and moving, mountains suddenly arise and rivers are sunk and drowned. Human things become utterly extinguished and ancient traces entirely disappear; this is called the 'Great Waste-Land of the Generations'. I have seen on high mountains conchs and oyster shells, often embedded in the rocks. These rocks in ancient times were earth or mud, and the conchs and oysters lived in water. Subsequently everything that was at the bottom came to be at the top, and what was originally soft became solid and hard. One should meditate deeply on such matters, for these facts can be verified.

### PHOSPHORESCENT PAINT

TENTH CENTURY AD

The Chinese have been fascinated by natural luminescence since the earliest times. Fireflies appear in one of the oldest surviving texts, the *Book* 

of Odes, which dates from at least the early centuries of the first millennium BC. 'Flashing go the night-travellers', says an old folk-song in this work. A traditional story is preserved in an early official history of the impoverished but diligent student Ch'e Yin (who died about 397 AD). His family was too poor to buy oil for him to study at night, so he collected a bagful of fireflies each evening and read by their light.

The connection between the bio-luminescence of fireflies and the glowing of certain kinds of rotting vegetation was certainly made by the Chinese. By the seventh century BC, a book entitled the Monthly Ordinances of the Chon Dynasty provided the somewhat garbled observation that 'decaying grass becomes fireflies'. Luminescence was recognized as being common to the two, and perhaps at this period the Chinese actually thought that fireflies were engendered in this way. But the luminescence of decaying vegetation was clearly recognized in its own right, as we see from a book of the second century BC which states that 'old pieces of Sophora wood shine like fire', and the official history for 466 AD which tells us: 'In the time of the Emperor Ming ... a Taoist, Sheng-Tao, from a mountain temple ... reported that a pillar in an apartment next to the Hall of Salvation was spontaneously shining brightly in the dark. Thus wood had lost its natural properties. Some people said that when wood goes rotten it shines of itself."

A clear understanding of these phenomena was somewhat impeded and complicated by numerous accounts of marsh-fires. These may be caused by burning methane gas, though even today we are not certain what causes 'marsh lights'. The statesman and poet Chang Hua described in his *Records of Strange Things* (290 AD) both will-o'-the-wisps and static electricity:

These lights stick to the ground and to shrubs and trees like dew. As a rule they are invisible, but wayfarers come into contact with them sometimes; then they cling to their bodies and become luminous. When wiped away with the hand, they divide into innumerable other lights, giving out a soft crackling noise, as of peas being roasted. If the person stands still a good while, they disappear, but he may then suddenly become bewildered as if he had lost his reason, and not recover before the next day.

LEFT (127) A glow-worm (Lampyris noctiluca), whose glowing tail is visible at night over long distances. Glow-worms were described in 1596 by Li Shih-Chen. who correctly differentiated them from fireflies and other apparently luminous creatures such as mayflies or midges infected with luminous bacteria. Luntinescence and phosphorescence fascinated the Chinese for centuries, and were called 'yin fire'. As the poet Ts'ao T'ang wrote in the ninth century: 'Yin-fires are cool'. This is a fact well known to a culture which collected naturally phosphorescent whale eyes ('night-shining pearls') and glowing luminescent minerals, and was using phosphorescent paint by the tenth century.

Nowadays it happens that when people are combing their hair, or when dressing or undressing, such lights follow the comb, or appear at the buttons when they are done up or undone, accompanied likewise by a crackling sound.

Chang Hua gives good evidence of the meticulous empirical observational powers of the protoscientists of early China. This tradition led, by the eleventh century AD at the latest, to the exploitation of natural luminescence in the making of phosphorescent paintings. We are given this account of the acquisition of one of these rare objects in an obscure book called *Rustic Notes from Hsiang-Shan*, written at that time:

The Provincial Legate Hsu Chi was fond of collecting curios. He paid 50,000 mace [coins] to a barbarian merchant for a stuffed bird's head, very brightly coloured, which he used as a pillow. He also got hold of an extraordinary painting which he presented to Li Hour Chu [the third and last Emperor of the Southern T'ang Dynasty; this can be

dated to 977 AD]. This ruler upon the extinction of the Southern T'ang passed it on as tribute to the second Sung Emperor, T'ai Tsung. T'ai Tsung hung it up in the back garden of the palace in order to show it to the court. On the painting there was an ox which during the day appeared to be eating grass outside a pen, but at night seemed to be lying down inside it. None of the officials could offer any explanation for this phenomenon. Only the monk Tsan-Ning, however, said that he understood it.... [He] said that it would be found in a book called the Hai Wai I Chi written by Chang Ch'ien [a famous envoy of the second century BC]. Afterwards Tu Hao examined the collections in the imperial library, and found the reference in a manuscript dating from the Liu Ch'ao period [third to sixth centuries AD].

The first production of a phosphorescent substance in the West appears to have been in 1768 by John Canton, who used oyster shells to prepare an impure calcium sulphide by calcining the carbonate with sulphur. It became known as Canton's phosphorus, but appears to owe nothing to China.

# FRANSPORTATION AND EXPLOR

### THE KITE

FIFTH/FOURTH CENTURY BC

The kite was not known in Europe before the sixteenth century. It is first mentioned (as a 'flying sail') in 1589 by the scientist Giambattista della Porta in *Natural Magic*, which was a popular book of marvels and tricks. Kites existed in China, however, as early as the fifth or fourth centuries BC. The earliest record of the construction of a kite is semi-legendary, but is probably based on fact. A man named Lu Pan of the fifth century BC was the historical basis for a tutelary god of artisans, named in later ages Kungshu P'an. Kungshu P'an is reported to have made kites, and it is thought that this bears relation to something that the real historical figure, Lu Pan, actually did.

Kites were in any case certainly constructed in the fourth century BC by the philosopher Mo Ti. Kungshu P'an and Mo Ti (who died 380 BC) were actually contemporaries. The stories of their kite-making were famous in Chinese tradition. Kungshu P'an made kites shaped like birds which could fly for up to three days; he also made his kites do somersaults. Mo Ti is said to have spent three years building a special kite, and we may safely assume that his followers, the Mohists, were much concerned with kite design.

The Mohists were preoccupied with military technology, and consequently many of the earliest stories of kites in China concern military uses. Indeed, Kungshu P'an is said to have flown one of his kites over the city of Sung during a siege, though how he utilized it is unclear. From the book *Things Uniquely Strange*, which dates from the seventh or eighth century AD, we have this interesting account of the military uses of kites:

In the T'ai-Ch'ing reign-period [547–9 AD] of Liang Wu Ti, Hou Ching rebelled, and besieged T'ai-ch'eng [Nanking], isolating it from loyal forces far and near. Chien Wen [later emperor for one year in 550] and the crown prince Ta-Ch'i decided to use many kites flying in the sky to communicate knowledge of the emergency to the army leaders at a distance. The officers of Hou Ching told him that there was magic afoot, or that messages were being sent, and ordered archers to shoot at the kites. At first they all seemed to fall but then they changed into birds which flew away and disappeared.

This either refers to kites shaped as birds, which were very common, or implies that the besieged forces switched to carrier pigeons as their means of sending messages. An early example of an airborne 'leaflet drop' – perhaps the first in history – occurred in the year 1232 with the aid of kites. The Mongols were laying siege to the Chin Tartars at K'aifeng, and the official history describes it thus:

The besieged sent up paper kites with writing on them, and when these came over the northern [Mongol] lines, the strings were cut so that they fell among the Chin prisoners there. The messages incited them to revolt and escape.

OPPOSITE (128) A nineteenth-century Chinese painting showing a celebration where fireworks are being set off in a small (apparently brick) kiln. Above the testivities, two lanterns are suspended and ornamental kites are being flown. This may be intended to represent the annual Moon Festival, as a full moon is prominent in the twilit scene. (Bridgeman Art Library.)

The Chinese were always most ingenious in their use of kites. They developed a technique of using them for fishing. The hook and bait would be attached to a kite and flown from a boat on a wide river or a lake, and would come to rest at some distance sufficiently far from the boat's shadow to deceive even the canniest of fishes.

The variety of kites in China is extraordinary. Apart from the traditional bird shape there are kites in the forms of centipedes, frogs, butterflies, dragons and hundreds of other creatures, both real and imaginary. Some have rolling eyes or moving paws and tails.

Musical kites seem to have existed in China since the seventh or eighth century. They make whistling, moaning or harp-like sounds. A kite fixed with a single bamboo strip is a 'wind psalter', or a 'wind zither'. A kite with seven strings fixed across a gourd-shaped framework is called a 'hawk lute'. Such Aeolian harps and whistles are not peculiar to kites. Whistles are also often put into the tails of pigeons.

The use of kites in China was intimately connected with a concept of what Needham translates into English as the 'hard wind'. This idea of the Taoist philosophical school partly derived from the early shaman traditions, where mystical journeys through the air were 'experienced' either in trance or with the aid of drugs. In the early *Lieh Tzu* book, parts of which date from the fifth century BC, we read that: 'Lieh Tzu could ride upon the wind. Cool and skilfully sailing, he would go on for fifteen days before returning.'

Kite flying seems to have been a kind of meditative exercise for the early Taoists, and had a similar significance to that which archery had to the later Zen Buddhists. One may imagine an early Taoist meditating upon the Way of the Universe as he flew his kite. His reveries are combined with an intimate contact with the actual aerial phenomenon of the wind, and the need to keep altering the tension of the string and compensating for wind changes. The sage might regard this as an analogy for 'following the Way', which was also often compared to 'following the grain of the Universe', with the grain of wood as the analogy.

The subtle variations in air currents with which the sage would have developed familiarity would have been associated with his reveries and the 'imaginary flights' of his mind. We can thus understand how Lieh Tzu is described as depending upon the wind when he 'rides upon it' in his fancy. But there is the further possibility that the Taoists are referring at this early date to man-lifting kites.

In one of the two greatest classics of Taoism, the book called *Chuang Tzu* ('The Book of Master Chuang'), which dates from about 290 BC, we read of more soaring into the air, and are given some opinions about the nature of air, and how it bears things up:

In the Northern Ocean there is a fish, by the name of k'un, which is many thousand li in size. This fish metamorphoses into a bird by the name of p'eng, whose back is many thousand li in breadth. When the bird rouses itself and flies, its wings obscure the sky like clouds ... it flaps along the water for three thousand li. Then it ascends on a whirlwind up to a height of ninety thousand li, for a flight of six months' duration.... Without sufficient density, the wind would not be able to support the large wings. Therefore when the p'eng had ascended to ninety thousand li, the wind is all beneath it. Then ... no obstacle ahead of it, it mounts upon the wind and starts for the south.

This is the very bizarre myth with which the *Chuang Tzu* opens. The concept of air density is literally expressed as 'thickness of condensation'. Burton Watson, in his translation of the *Chuang Tzu*, renders it 'piled up deep enough'. The early Taoists were much preoccupied with the actual nature of air and wind, and they formulated a concept of the 'hard wind' to express the aerial capacity to lift a kite. It was in fact the pressure exerted by a moving airstream on the undersurface of an airfoil.

The Chinese did develop cambered-wing kites, with surfaces like wings, curved upwards at the top and either concave or flat underneath. But we cannot fix any date for this. We do not know whether or not the early Western designers of aircraft, such as Sir George Cayley in the nineteenth century, knew of Chinese cambered kites. But the chief influence of the kite on aviation was the invention in 1893 of the box kite by the Australian Lawrence Hargrave. Box kites were copied by bi-plane builders later. And until 1910, books on aviation generally began with introductory chapters on kites because of these origins. Early aviators even tended to use the slang term 'kites' to refer to their aircraft at the

beginning of this century. Such was the heritage of the kite, which the Chinese had for two thousand years before the Europeans.

### MANNED FLIGHT WITH KITES

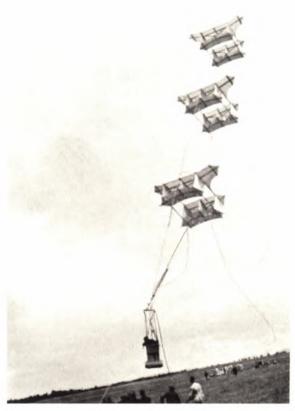

FOURTH CENTURY BC

The earliest specific description which gave physical details of manned flight with kites occurs in historical accounts of the short-lived and obscure Northern Ch'i Dynasty. This dynasty existed for only 27 years, between 550 and 577 AD. The incidents described here occurred at the end of a century of disintegration preceding the third unification of China and the start of what is generally thought of as its Golden Age; at this time Europe was still in the throes of the Dark Ages.

Our historical account of man-flying kites comes from a rather gruesome episode in history when the first emperor of the Northern Ch'i, Emperor Kao Yang, who reigned from 550 to 559, carried out a systematic extermination of the entire Yuan family (whose original surname was T'opa, which because it was not Chinese they changed to Yuan to facilitate social assimilation), who had controlled the previous Wei Dynasty. In the last year of his reign alone, no less than 721 members of the family were massacred on his orders. Many of these murders were carried out with a sinister ingenuity.

Having embraced Buddhism, the Emperor Kao Yang went to receive his ordination at the Tower of the Golden Phoenix, north-west of the capital city of Yeh near modern Lin-chang, north of the Yellow River. In the ancient Chinese exercise of piety called 'the liberation of living creatures', fish and birds were released after they had been caught. The Buddhists took on this practice, believing that it conferred merit on a pious man. In a typical example of the perverse and insane behavior of one of China's most evil emperors, Kao Yang celebrated his Buddhist ordination with a ceremony which he also called

ABOVE (129) *Left:* American aeronautical pioneer Colonel Samuel Franklin Cody's man-lifting kite, in England, 1905, carrying Sapper Moreton, officer of the British Royal Engineers. On this occasion, Moreton rose 2,600 feet and remained there for one hour. Cody (1867–1913) was the first person actually to fly in his own kite. *Right:* Lieutenant Bassel in a man-lifting multi-stage kite in France, 1909. (From E. Charles Vivian, *A. History of Aeronautics*, London, 1921.)

INSPORTATION AND EXPLORATION

'the liberation of living creatures'; but his version of it was somewhat different.

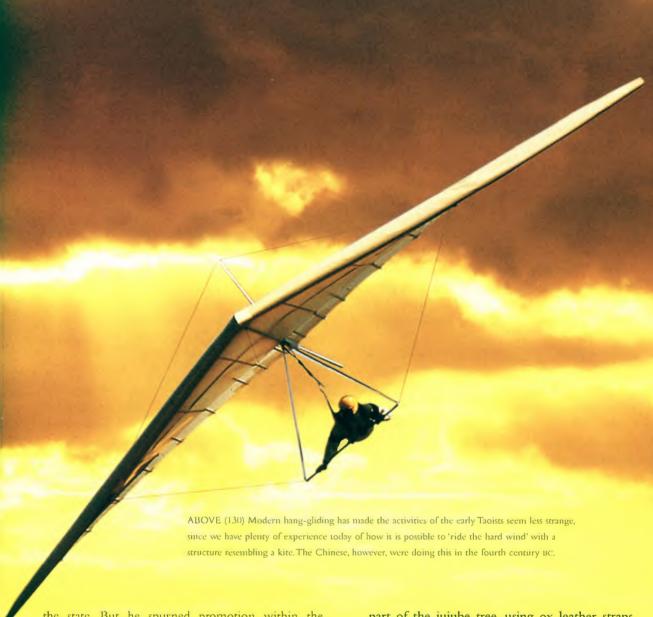

The creatures he decided to 'liberate' were his enemies, the T'opa and Yuan families, and his method was to throw them from the top of the 100-foot tower. As the official history tells us: 'He caused many prisoners condemned to death to be brought forward, had them harnessed with great bamboo mats as wings, and ordered them to fly to the ground from the top of the tower. This was called a "liberation of living creatures".' We are also told that 'All the prisoners died, but the Emperor contemplated the spectacle with enjoyment and much laughter.'

The Emperor's aerodynamic fancies then underwent a further development, and he became determined to carry his amusing experiments to more exciting lengths. By 559, the last year of his reign, he was regularly using condemned prisoners to jump from the Tower of the Golden Phoenix as test pilots for man-flying kites. Needham comments: 'The circumstances show that what was going on was not quite simply a cruel emperor's sport with prisoners, for the cables of the kites must have required manhandling on the ground with considerable skill, and with the intention of keeping the kites flying as long and as far as possible.' One prince of the Wei, a prominent member of the Yuan family, was able to

make a very successful flight for what seems to have been about two miles. The incident is described in a history of the period called the *Comprehensive Mirror* of History for Aid in Government, which was compiled from official documents of the time:

Kao Yang made Yuan Huang-T'ou and other prisoners take off from the Tower of the Golden Phoenix attached to paper kites in the form of owls. Yuan Huang-T'ou was the only one who succeeded in flying as far as the Purple Way, and there he came to earth. But then he was handed over to the President of the Censorate, Pi I-Yün, who had him starved to death.

The famous Taoist author Ko Hung (283–343 AD) is called by Needham 'the greatest alchemist of his age, and the greatest Chinese alchemical writer of any age'. Ko Hung was an all-round scientist who discussed natural phenomena of all kinds, and he greatly concerned himself with astronomy and geology. He had a love of the exotic and the strange, and repeatedly emphasized that conventional ideas about nature were inadequate. When younger he had achieved prominence and fame as a soldier, suppressing the rebellions of 303 AD. Many years later, he was given the title of Marquess for these early services to

the state. But he spurned promotion within the bureaucracy in order to pursue his scientific interests. He was friendly with the best scholars of his day.

Needham wrote of Ko Hung: 'His words about the series of different kinds of animals would be incomprehensible if we did not know well the perennial Chinese tradition of making kites in the shapes of animals. I have no doubt that what he was referring to were man-lifting kites.' Here is the passage, about manned flight in the fourth century, in which Ko Hung is referred to as the Master:

Someone asked the Master about the principles of mounting to dangerous heights and travelling into the vast inane. The Master said ... 'Some have made flying cars with wood from the inner

part of the jujube tree, using ox leather straps fastened to returning blades so as to set the machine in motion. Others have had the idea of making five snakes, six dragons, and three oxen to meet the "hard wind" and ride on it, not stopping until they have risen to a height of forty li [about 65,000 feet]. That region is called the Purest of Empty Space. There the ch'i [emanation of the sky, or perhaps wind] is extremely hard, so much so that it can overcome the strength of human beings. As the Teacher [we do not know who is meant by Ko Hung here, but perhaps he refers to the Taoist sage known as Chuang Tzu] says: "The kite [bird] flies higher and higher spirally, and then only needs to stretch its two wings, beating the air

no more, in order to go forward by itself. This is because it starts gliding on the 'hard wind'. Take dragons, for example; when they first rise they go up using the clouds as steps, and after they have attained a height of forty *li* then they rush forward effortlessly, gliding." This account comes from the adepts and is handed down to ordinary people, but they are not likely to understand it.'

As Needham says: 'For the beginning of the fourth century AD this is truly an astonishing passage.... There can be no doubt that the first plan which Ko Hung proposes for flight is the helicopter top; returning (or revolving) blades can hardly mean anything else, especially in close association with a belt or strap.

On the rest of the passage Needham goes on to say:

I have no doubt that what he was referring to were man-lifting kites, and though as yet we have no evidence that Ko Hung or any of his contemporaries constructed such large instruments, there would have been really nothing to prevent it. For people expert in kite-flying the possibility was obvious.... Lastly, what is to be said of Ko Hung's 'hard wind'? From the examples he gives of the gliding and soaring of birds, it is obviously nothing else than the property of 'air-lift', the beating or rising of the inclined aerofoil subjected to the forces of an airstream, whether natural or artificial.... Ko Hung applies the concept ... very clearly to gliding flight, as indeed had Chuang Chou [Chuang Tzu] before him, when he wrote [in the fourth century BC] about the wings of the giant p'eng bird being airborne upon the density of the wind beneath. Ko Hung ends by attributing to him the idea that flying things rise up 'using the clouds as steps', which may be more than a poetic metaphor, hinting as it does at the existence of those ascending air-currents which modern glider pilots have learnt so well to utilize. Something of these could probably have been observed in the behaviour of smoke, and particularly of the mists and clouds on the lofty mountain heights which the Taoists delighted to frequent.

The Taoists had been taking refuge in obscure mountain sanctuaries for centuries. There they passed on their traditions orally from master to pupil, leaving much of the more esoteric lore unwritten. Kite flying, and flying with the aid of kites, was not only suited to the high and windy locations where these early adepts of aviation lived, but was most probably a pursuit viewed as immensely important, and carried out in great secrecy. A sage would be no more inclined to impart the secrets of how he was imitating the birds and learning how to ascend bodily to heaven, than he would be likely to explain to the man in the street how to make an elixir of immortality, or how to make 'gold' in a secret cave laboratory. By virtue of these pursuits the Taoists are now thought to be the true proto-scientists of early China.

By the thirteenth century, man-lifting kites were widely used throughout China. A dramatic account of the practice was given by Marco Polo in a version of his book called the 'Z' Manuscript:

And so we will tell you how when any ship must go on a voyage, they prove whether her business will go well or ill. The men of the ship will have a hurdle, that is a grating, of withies [willow stems], and at each corner and side of this framework will be tied a cord, so that there be eight cords, and they will all be tied at the other end of a long rope. Next they will find some fool or drunkard and they will bind him on the hurdle, since no one in his right mind or with his wits about him would expose himself to that peril. And this is done when a strong wind prevails. Then the framework being set up opposite the wind, the wind lifts it and carries it up into the sky, while the men hold on by the long rope. And if while it is in the air the hurdle leans towards the way of the wind, they pull the rope to them a little so that it is set again upright, after which they let out some more rope and it rises higher. And if again it tips, once more they pull in the rope until the frame is upright and climbing, and then they yield rope again, so that in this manner it would rise so high that it could not be seen, if only the rope were long enough. The augury they interpret thus; if the hurdle going straight up makes for the sky, they say that the ship for which the test has been made will have a

quick and prosperous voyage.... But if the hurdle has not been able to go up, no merchant will be willing to enter the ship....

This must surely be one of the strangest forms of divination or fortune-telling in history!

In modern times, men have flown in kites. Since Pocock's attempts in 1895, many more have been made in Europe. B.F.S. Baden-Powell was the first European to achieve full success with man-flying kites in 1894. Therefore, if we take Yuan's successful flight in 559 AD as the first in the world from the point of view of historical record, we have a gap of 1335 years between the Chinese precedent and Europe's first flight.

Nowadays, the widespread use of hang-gliders by ordinary members of the public makes early Chinese manned flight in kites more credible than it would

ABOVE (131) A bronze incense-burner of the fourth or third century BC representing the mysterious mountain paradise of P'eng Lai, which the Chinese believed existed on the far side of the Pacific. It was customary to represent P'eng Lai in this way, with three-dimensional peaks and contours, often inlaid with precious or semi-precious stones. Such censers were a powerful influence in the development of relief maps during the third century BC. The earliest relief map in Europe dates from 1510. (Freer Gallery of Art, Smithsonian Institution, Washington D.C.)

have been even a few decades ago. Skilled hang-glider pilots understand the nature of the air currents referred to by Ko Hung, and know how to use an ascending current of hot air to rise to over 2000 feet, simply by spiraling up with it. This is, in other words, 'using the clouds as steps' and 'flying higher and higher spirally', as described by Ko Hung, even if his figure of 65,000 feet must be a gross exaggeration. It would appear that the early Taoists did achieve dramatic success in manned kite-flying long before Ko Hung – rising to at least 2,000 feet – and probably over two thousand years ago. But even if we take the generation before Ko Hung as a conservative estimate for the date of the first attempt, we must still acknowledge the existence of manned flight with kites as having been no later than 250 AD - or well over seventeen hundred years ago.

### THE FIRST RELIEF MAPS

THIRD CENTURY BC

The Chinese were the first to use relief maps, where the contours of the terrain were represented in models. Relief maps in China go back at least to the third century BC. In the great historical classic, the Shih Chi (Historical Records) of Ssuma Ch'ien (90 BC), there is preserved an account of probably the most famous relief map ever made. It was built in 210 BC for the tomb of the unifier of China, the megalomaniac emperor Ch'in Shih Huang Ti, and showed his conquests and empire. The history says:

In the tomb-chamber the hundred water-courses, the Yangtze River and the Yellow River, together with the great sea, were all imitated by means of flowing mercury, and there were machines which made it flow and circulate. Above [on the ceiling] the celestial bodies were all represented; below [presumably on the floor or on some kind of table] the geography of the earth was depicted.

In the mid-1980s, the tomb of this emperor was located, but it has not yet been opened and its investigation has been postponed for some time. Traces of mercury have been found in the soil around what is thought to be the entrance. Archeologists have already suggested that this is the

LEFT (132) Relief maps led to two-dimensional contour maps like the one on the left. This is a representation of the sacred T'ai Shan mountain range from a seventeenth-century edition of a much older book, Map of the Tine Topography of the Fire Sacred Mountains. To far left, for comparison, is a modern contour map.

very mercury which circulated in the relief map described above. If this be so, we may be on the verge of one of the most exciting archeological discoveries ever made, for the ancient relief map will presumably still be largely intact. The descriptions which survive state that it was carved out of solid rock by the labour of 700,000 convicts. It was therefore absolutely enormous. Automatically triggered crossbows were set up to fire at intruders, and if the strings have survived these would still be in working order.

The Chinese had a curious and persistent legend about an island mountain paradise, named P'eng-Lai, in the Eastern Seas (that is, the Pacific). It was said to be an abode of sages and a heaven upon earth, frequented by the mysterious immortals who, on drinking elixirs of life, had etherealized their bodies, become 'feathered', and were able to soar into the sky. Expeditions were sometimes sent to P'eng-Lai, and at least one full-scale naval task force went in search of the paradise but failed to return. We may never know for certain where this legend originated; perhaps P'eng-Lai was Tahiti, or Hawaii, or even America, but it was often depicted in relief on Han Dynasty pots and censers, dating from the third century BC. One such 'relief map' jar may be seen in Plate 131 (page 195). These jars had a powerful influence in developing relief map techniques.

A description survives of strategic relief maps made by the general Ma Yüan in 32 AD. The valleys and mountains were represented by modeling in rice. Such military relief maps were so useful that Chiang Fang wrote a special book entirely on the subject, entitled *Essay on the Art of Constructing Mountains with Rice* (c. 845).

Relief maps were also carved in wood. This led to what appears to be the invention of the jigsaw puzzle. We have this description of a 'jigsaw map' in the official history of the Liu Sung Dynasty:

Hsieh Chuang (421–66) made a wooden map 10 feet square, on which mountains, water-courses and the configuration of the earth were all well shown. When one separated the parts of the map then all the districts were divided and the provinces isolated; when one put them together again, the whole empire then once more formed a unity.

The great scientist Shen Kua wrote the following interesting account in his book, *Dream Pool Essays*, of 1086:

When I went to a government official to inspect the frontier, I made for the first time

a wooden map upon which I represented the mountains, rivers and roads. After having explored personally the mountains and rivers [of the region], I mixed sawdust with wheatflour paste [modelling it] to represent the configuration of the terrain upon a kind of wooden base. But afterwards when the weather grew cold, the sawdust and paste froze and was no longer usable, so I employed melted wax instead. The choice of these materials was dictated by the necessity of making something light which would not be difficult to transport. When I got back to my office [in the capital] I caused [the relief map] to be carved in wood, and then presented it to the emperor. The emperor invited all the high officials to come and see it, and later gave orders that similar wooden maps should be prepared by all prefects of frontier regions. These were sent up to the capital and conserved in the imperial archives.

A wooden relief map was also made by Huang Shang in 1130, which later attracted the attention of one of China's greatest Confucian philosophers, Chu Hsi, who was born in that year and died in 1200. He attempted to find the relief map so that he could study it, and made his own ones, using clay as well as wood. The quaintly named book *Jade Dew from the Forest of Cranes* preserves this description of one of his maps:

Chu Hsi also made a wooden map of the countries of the Chinese and Barbarians, upon which the convexities and concavities of mountains and rivers were carved. Eight pieces of wood were used, with hinges to connect them together. The map could be folded and one person could carry it. Whenever he travelled, he took this along with him. But it was never really completed.

It is quite likely that the idea of making relief maps was transmitted to the Arabs from the Chinese, and thence eventually to Europe. The earliest certain relief map in Europe was made in 1510 by Paul Dox, showing the neighborhood of Kufstein in Austria. The Arab Ibn Battutah (1304–77) gave an account of a relief or raised map which he saw at Gibraltar. Nothing earlier than this is known outside China.

# THE FIRST CONTOUR TRANSPORT CANAL

THIRD CENTURY BC

The Chinese built the world's first contour transport canal (that is, exploiting and following the contour of the land as a way around or over hills) in the third century BC. There is no question that the Chinese were the greatest civil hydraulic engineers in history until modern times. A few facts about the Grand Canal, that gigantic artery for transport by barge, are sufficient to make the point. The Grand Canal was built over many centuries. It extends nearly 10 degrees of latitude on the globe, attaining a length of nearly 1100 miles, and achieves a summit height of 138 feet above sea level. A good way to envisage it is to imagine a broad canal extending from London to Tangiers or from New York to Florida. This great engineering feat was complete by the year 1327.

Nothing remotely approaching the Chinese canal systems existed in Europe until the four great seventeenth-century canals in France, the last of which was not finished until 1775. But none of these

ABOVE (133) The headworks of the Magic Canal. North is at the top left-hand corner. The waters of the Hsiang River flow in from the right, and meet the 'Spade Snout', which divides the waters into two channels. The 'Spade Snout' is flanked on either side by large spillways, to drain away some of the water and reduce the force of the current. The Hsiang continues along the northwards course, and the Magic Canal commences with the channel running along the bottom of the diagram. Massive embankments and walls of dressed stone line the length of the canal. Further spillways keep the water level under control. The canal is 15 feet wide and the water is 3 feet deep. The canal's length is just over 20 miles. It links two rivers flowing in opposite directions, thus making possible continuous inland navigation for a distance of 1250 miles, from the latitude of Peking to Canton. This canal was thus a major economic and military development for China, foreshadowing the later Grand Canal, which runs for nearly 1100 miles.

was longer than 150 miles. There were only 630 miles of canals in all France by the end of the eighteenth century, and even by 1893 the total mileage of French canals had only reached three times the length of China's Grand Canal alone in 1300. The Grand Canal is between 10 and 30 feet deep and often 100 feet broad, whereas the early nineteenth-century canals of England were only 5 feet deep and 45 feet broad. Needham estimates that 'the canals of all Europe probably still fall short of the Chinese artificial navigable waterways in mileage.'

There is no doubt that the ancient Babylonians were highly advanced in irrigation canals, but we are uncertain to what extent they had progressed in transport canals, sluice gates, and so on. Evidence for the use of sluice-gates by the Phoenicians goes back to the second millennium BC in the harbour at Sidon. As regards non-Babylonian canals, an Egyptian canal connecting the Nile with the Red Sea was commenced by Necho (610-595 BC), but was only completed under Ptolemy Philadelphus about 280 BC. There was a slipway across the Isthmus of Corinth by the early sixth century BC which remained in use until the ninth century AD; it was not a canal, and ships were pulled on slipways at either end and carried on wheeled cradles along a masonry road for most of the length. Ancient Egyptian waterworks connected with the Nile were seasonal and intended to help with both irrigation and silt deposition, rather than to act as transport arteries.

The greatest canal of Middle Eastern antiquity was apparently the Nahrawan Canal of about the third century AD, which ran for about 250 miles with an impressive breadth of 400 feet, emanating from and

then rejoining the Tigris river. The Babylonian area had much earlier seen vast networks of irrigation canals radiating outwards from the rivers attempting to ensure perennial water supply and to transform the river valleys into artificial deltas. There may have been canals built specifically for transport, but they would not have been contour ones, rather glorified irrigation canals in a flat landscape. We must also not ignore

India, and must acknowledge that Nandivardhana constructed a transport waterway in the fifth century BC. Unfortunately, the history of these ancient non-Chinese constructions is still buried in considerable obscurity because of the lack of surviving evidence.

In China, the Hung Kou transport canal is thought to have been the first to be constructed. It was apparently built in the sixth century BC. However, what is of particular interest to us is the world's first contour transport canal, of the third century BC, the Magic Canal (Ling Ch'ü). This was indeed a most impressive pioneering achievement. It was constructed by the engineer Shih Lu on the orders of the Emperor Ch'in Shih Huang Ti, the tyrannical and superstitious monster who first unified China. The impetus for this innovative type of canal was to assist in supplying the emperor's armies sent south in 219 BC to conquer the people of Yüeh. We are told by the great historian Ssuma-Ch'ien that:

[the emperor] sent the Commanders (Chao) T'o and T'u Chu to lead forces of fightingmen on boats with deck-castles to the south to conquer the countries of the hundred tribes of Yüeh. He also ordered the Superintendent (Shih) Lu to cut a canal so that supplies of grain could be sent forward far into the region of Yüeh.

The Magic Canal, which is still used today, is just over 20 miles long. Its chief interest is thus not its length, which is unexceptional. The construction of the Magic Canal, linking as it did two rivers flowing in opposite directions, made possible the continuous

RIGHT (134) A view of the Magic Canal, with one of the boats currently in use on it.

LEFT (135) A spillway of the world's oldest contour transport canal, the Ling Ch'u, or Magic Canal, which connects the River Li and the River Hsiang and was constructed in the third century BC (though since restored and improved).

inland navigation of barge transport for a distance of 1250 miles in a direct line, from the fortieth to the twenty-second parallel. One could thus sail inland from the latitude of Peking in the north as far as Canton and the sea – to what is today Hong Kong. The Magic Canal was the final link in the chain.

The problem that had to be overcome was that the River Hsiang, with its source at Mount Haiyangshan, flowed northwards, while the nearby River Li flowed southwards. If only one could get a boat from one to the other! – for the Hsiang led eventually to the Yangtze and the Li joined a tributary of the West River and led to Canton. Near the little village of Hsing-an, the Hsiang and the Li, in a landscape of limestone hills, are only three miles apart. Simply joining them was not sufficient. Another solution had to be found.

There was a saddle in the hills at this point along which a canal could be dug. The rivers themselves were unruly and a lateral transport canal had to be dug alongside the Hsiang river for 1½ miles at a more even gradient than the river itself had. At the other end, 171/2 miles of the Li river had to be canalized in order to regulate it and make navigation possible. Only with the two rivers 'tamed' at either end like this could a 3-mile canal then be dug to join them. A mound shaped like a snout was constructed in the middle of the swiftly running Hsiang to divide its flow, and lead off much of the rushing water. It was backed up by two spillways, and further spillways were made lower down. Several bridges at Hsing-an were constructed to cross the canal, which was 3 feet deep and 15 feet wide. The system of division of the waters and spillways resulted in only about three-tenths of the water from the Hsiang entering the connecting canal, so that it was not overwhelmed.

By being built along the contours of the saddle in the hills, the canal was nearly level. Eighteen flash-lock gates were there by the ninth century at the latest, reducing the number of towers needed for barges by regulating the level and the flow. They

were changed to pound-locks by the tenth or eleventh century. The Magic Canal came to be considered a sacred waterway, with a dragon as its governing spirit. The dragon's emissaries were said to be blue snakes called 'dragon colts', which coiled playfully in the hands of visitors. A modern railway bridge goes right over the old Magic Canal, which is still used. Unless one knows its importance, it does not seem particularly impressive, and can easily be missed. But no comparable canal seems to have been built in Europe until the beginning of the thirteenth century.

#### THE PARACHUTE

SECOND CENTURY BC

Most people know that Leonardo da Vinci left sketches of the parachute, which was the first appearance of the idea in Europe. However, the Chinese seem to have invented the parachute and actually used it well over 1500 years before Leonardo.

The first textual evidence we have for this is in the famous *Historical Records* of China's greatest historian, Ssuma Ch'ien, which was completed about 90 BC. We can therefore safely consider the parachute as dating from at least the second century BC. Ssuma Ch'ien had access to vast archives, and the fact that he attributed the parachute to such remote antiquity means that its origins may well have been some centuries before this time.

As the story goes, the legendary hero, Emperor Shun, was fleeing from his father, who wanted to kill him. He took refuge in a large granary tower, and his father set fire to it, hoping to burn him to death.

ABOVE (136) This is a famous sketch of a man descending on a parachute, drawn by Leonardo da Vinci (1452–1519) in his notebooks. Until the Chinese invention of the parachute 1,500 years earlier was recognised, people thought that the original inventor must have been da Vinci himself. It is conceivable that da Vinci had heard of parachutes in China. Marco Polo (1254–1324) had not only visited China, along with other Italians, two centuries earlier, but had left a detailed description of a man-flying kite in his own memoirs so that such things were 'in the air'.

But Shun tied a number of large conical straw hats together and jumped, using them as a parachute. From this we can assume that there was indeed a jump by someone and that over the years the tale became attached to a legendary episode in the life of Shun. There was a commentary on the story in the eighth century AD by Ssuma Chen (a different person from the historian just mentioned), who remarked that the hats acted like the wings of a bird, making Shun's body light and bringing him safely to the ground.

Needham brings forward a medieval mention of the use of the parachute, from a book called *Lacquer Table History* by Yo K'o. This book was published in 1214 and recounts events witnessed at Canton in 1192. In Canton at that time there was a large Arab community of merchants, who had their own mosques, one of which had a 'grey cloud-piercing minaret like a pointed silver pen' with a spiral staircase inside. At the very top was a huge golden cock, which was missing one leg. The leg had been stolen in 1180 by a cunning thief who had escaped by parachute. The robber's own account is preserved, for he seems to have been something of a local hero. He describes the escape as follows: 'I descended by

holding onto two umbrellas without handles. After I jumped into the air the high wind kept them fully open, making them like wings for me, and so I reached the ground without any injury.'

We have documentary evidence that the first construction and use of a parachute in Europe was due to a report of a visitor to Thailand, who witnessed its use by Chinese and Siamese acrobats. The account was written by Simon de la Loubère, appointed Ambassador to Siam by King Louis XIV of France from 1687 to 1688. In his *Historical Relation* he wrote:

There dyed [died] one, some Years since, who leap'd from the Hoop, supporting himself only by two Umbrella's, the hands of which were firmly fix'd to his Girdle; the Wind carry'd him accidentally sometimes to the Ground, sometimes on Trees or Houses, and sometimes into the River. He so exceedingly diverted the King of Siam, that this Prince had made him a great Lord; he had lodged him in the Palace, and had given him a great Title; or, as they say, a great Name.

The historian J. Duhem has established that L.S. Lenormand read this passage a century later, was stimulated to make trials, jumping from the tops of trees and buildings, and was quite successful. In 1783, Lenormand gave the invention its name of 'parachute'.

Lenormand told the brothers Joseph and Etienne Montgolfier about it, and the famous pioneering balloonists were then responsible for A.J. Garnerin's jump from a balloon with a parachute in 1797. This was a direct result of a Westerner having witnessed Chinese parachutes. Needham remarks, aptly: 'There are not many cases in which so clear a line of transmission is detectable.'

It should be noted that the parachutes used in Siam in 1687 were just the same as the one that had been used by the thief at Canton 500 years earlier, namely, a pair of umbrellas. It is quite possible that the Cantonese thief was himself a professional acrobat, and therefore knew how to use the parachute successfully — and even more important, had the confidence to jump. Probably the pair of umbrellas was a stock-in-trade of the highest calibre acrobats for hundreds of years.

In June 1985 a woman named Yang You-hsiang of Liao-chiao in Hopei Province in China was carried 550 yards in the air by a tornado. She landed safely because she had been carrying an open umbrella, which acted as a parachute. Her only injuries were from hailstones. (London *Daily Telegraph*, 22 June 1985.) Clearly very much in the national tradition!

#### MINIATURE HOT-AIR BALLOONS

SECOND CENTURY BC

By the second century BC, the Chinese were making miniature hot-air balloons using eggshells. A book that was written at that time, The Ten Thousand Infallible Arts of the Prince of Huai-Nan, mentions this pastime: 'Eggs can be made to fly in the air by the aid of burning tinder.'

An ancient commentary added to the text explains further: 'Take an egg and remove the contents from the shell, then ignite a little mugwort tinder inside the hole so as to cause a strong air current. The egg will of itself rise in the air and fly away.' Mugwort (Artemisia vulgaris) is a very common weed, the long, dried stalks of which were used in China as tinder for lighting fires, and powdered as a flammable element in incense sticks.

Few references are found in Chinese writings to the use of the hot-air balloon principle. Perhaps it was for a long time not thought worthy of much attention, but by medieval times the military possibilities were being exploited. There are several references in European chronicles to the use of hotair balloons, shaped like dragons, either for signaling or as standards by the Mongol Army at the Battle of Liegnitz in 1241. The principle was in all probability obtained from the Chinese; the Mongol Dynasty finally established full sway over all of China only 19 years after this.

Needham has pointed out that paper was available in China so many centuries before anywhere else (from the second century BC) that 'the development of the classical globular lanterns would have encouraged experimentation. When their upper openings were too small and the source of light and heat unusually strong, they must sometimes have shown a tendency to rise and float free of support.'

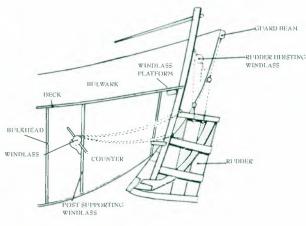

A vivid eyewitness description of the use of hotair balloons in the form of paper lanterns is provided by Peter Goullart, who lived between 1939 and 1949 in the Lichiang region of Yunnan Province in the south of China:

July, which was the critical month before the rainy season, had several festivals. With the rice already planted, the people did not have much to do and the evenings were devoted by the younger set to dancing and to flying the kounmingtengs - the lighted balloons. During the day one could see the young men ... pasting together the oiled sheets of rough paper to form the structure of a balloon. These balloons were then dried in the sun and were ready for use in the evening. Crowds gathered to watch. A bunch of burning mingtzes was tied underneath; the balloon swelled and quickly rose into the air to the shouts of excited spectators. The higher it rose the more good luck it promised to its owner. Some went up very high indeed and floated in the sky like red stars for several minutes. At the end they burst into flames and fell, sometimes causing fires by setting light to straw in unwatched farm-houses. Sometimes there were as many as twenty of these balloons floating through the dark sky. Balloon flying lasted for about a couple of weeks and it was great fun.

ABOVE (138) The stern of a Hong Kong fishing boat in dry dock, showing the 'fenestrated' rudder. The holes make it easier to turn the rudder through the water, but do not diminish the steering function. This Chinese invention was introduced to Europe in 1901. (Waters Collection, National Maritime Museum, London.)

ABOVE RIGHT (139) The rudder and tiller of a Hangchow Bay freighter. This is a 'balanced' rudder, that is, it curves round somewhat in front of the post (to the left in the diagram). It is also 'slung' by a tackle, which can be raised or lowered by the hoisting windlass. It is thus possible to pull the rudder entirely up above water level and pass over shallows without damaging the rudder.

LEFT (140)
The world's oldest depiction of a ship's rudder, on a pottery model of a ship dating from the first century AD.
(Kuangchow Historical Museum, Canton.)

### THE RUDDER

FIRST CENTURY AD

Until Europeans adopted the rudder from the Chinese, Western ships had to make do with steering oars. This meant that long voyages of discovery by Europeans were impossible. The famous voyages of Christopher Columbus, Vasco da Gama, and others of their time were only made possible by the adoption of Chinese nautical technology. The oldest Western evidence for rudders is found in church carvings of about the year 1180. This is within a few years of the first European evidence for the ship's compass. Rudders and compasses thus seem to have reached Europe at about the same time, which is hardly surprising, since they were so closely associated. The rudder enables one to steer a ship properly, and the compass helped one to decide where to steer it.

The world's oldest representation of a rudder may be seen in Plate 140 (left). This is a pottery model of a Chinese ship excavated from a tomb dated to the first century AD. The model is about 1 foot 10 inches long, and its rope slinging tackle has long since rotted away. But a slung axial rudder may clearly be seen. (A slung rudder is one which can be raised and lowered by rope tackle or chains; when entering shallows, it is often desirable to pull the rudder up so that it will not be snapped off.)

Chinese seagoing rudders grew to many times the size of a man. Huge ships with enormous rudders were used on the Chinese voyages of discovery which preceded the European ones. The Chinese sailed round the Cape of Good Hope in the opposite direction to

that taken by the Europeans and at an earlier time. They were also first to discover Australia, landing at the site now called Port Darwin. Chinese trade with the Philippines and Indonesia was common; and trade with the eastern coast of Africa was so extensive that pieces of broken Chinese porcelain are to be found scattered all up and down the beaches of Tanzania and Mozambique, dating back for centuries. The Chinese also made voyages to the American continents, though it is questionable whether they were return voyages. Many Asian influences have been identified in ancient America by Needham and others. But the Chinese who arrived were quite possibly stranded, unable to return home, owing to the greater difficulty of sailing westwards across the Pacific.

Another traditional Chinese invention was the 'fenestrated rudder', which put simply is a rudder with holes made in it (see Plate 138 (opposite)). The Chinese soon discovered that while easing the task of turning the rudder through the water, the holes did not appreciably diminish its steering function. However, it was not until 1901 that fenestrated rudders were introduced to the West. Until that time, a coal-fired torpedo boat travelling at 30 knots was unable to turn its rudder at speed. Fenestration made this possible.

The earliest rudders in China were what is called 'balanced' rudders. This means that part of the blade projected in front of the post. Such rudders are easier to use, but Europeans did not adopt them until the nineteenth century.

RIGHT (141) A Yangchiang fishing junk becalined. Note that the masts are staggered thwartwise, with the mast in the front being further to the left, and the masts behind being successively further to the right. This ingenious Chinese technique of preventing the sails from becalining each other was never adopted in the West. (Waters Collection, National Maritime Museum, London.)

One of the earliest ships to use such a rudder was the *Great Britain* of 1843. The British were in the forefront when it came to adopting Chinese inventions for naval use, with this as well as the square-pallet chain pump as a bilge pump (see page 63) and watertight compartments in hulls (see page 211). It is no exaggeration to say that the superiority of the British Navy was to a large extent due to its readiness to adopt Chinese inventions more rapidly than other European powers.

### MASTS AND SAILING

SECOND CENTURY AD

It could probably be safely said that the Chinese were the greatest sailors in history. For nearly two millennia they had ships and sailing techniques so far in advance of the rest of the world that comparisons are embarrassing. When the West finally did catch up with them, it was only by adapting their inventions in one way or another. For most of history, Europeans used ships which were drastically inferior to Chinese ships in every respect imaginable. They had no rudders, no leeboards, no watertight compartments, single masts, and square sails,

ABOVE (142) A three-masted sea-going Chinese junk of modern times, though few using only sails now remain, as engines have been widely adopted for convenience. This photo shows particularly clearly how the lug sails extend in front of the masts (that is, the front edge of the sail, known as 'the luff', is not behind the mast), which was a Chinese innovation, and that the sails are aligned parallel with the boat's long axis (not its keel, because Chinese junks do not have keels), rather than at right angles to it, as was the inefficient Western tradition. This fore and aft rigging enables a ship to tack into the wind, which Western ships were incapable of doing with their square sails at right angles to the boat's long axis, until the adoption of Chinese sailing techniques in the fifteenth century (which then enabled such explorers as Columbus to make their long voyages of discovery).

which left them at the mercy of the winds to an extent which today we would consider ludicrous. This continued to be the case even into the nineteenth century. As Needham says: 'As late as 1800 they sometimes had to wait as long as three months at Hamoaze in order to get into Plymouth Sound, and this was long after the introduction of a lateen sail on the mizzen mast.'

Chinese sails were innately superior to Western ones. Apparently commencing with sailing rafts, the Chinese had recourse to their native bamboo to aid sail construction. This led to the use of sails consisting of bamboo battens with matting stretched between them. Such sails could be hauled up and down like a set of open venetian blinds covered with cloth. Sailing in this way was easier than with Western canvas sails, for it was not necessary for sailors to climb along yard-arms to furl or unfurl the sails when the wind changed: everything could be done from the deck with windlasses and halyards. Furthermore, a sail with battens could be used

with as many battens exposed as one wished; in a gale, one could let two battens' worth of sail be exposed, but in a light breeze, the whole sail could be exposed to catch it. This added greatly to control of the vessel. Battens were not used in Western sails until modern racing yachts partially adopted them.

Bamboo and mat sails have another advantage: a ship can sail even if half of the sail consists of holes which have been torn in it, or which have appeared from rotting or other deterioration. A Western canvas sail could not work with so many holes. Also, the battens held Chinese sails taut, which was more efficient aerodynamically. There is unnecessary wind turbulence caused by sails which belly too much in the wind: this reduces speed. Even today, modern racing yachts are thought by some to have insufficiently taut sails and to allow far too much bellying. It is likely that there is still more to be learnt from Chinese sails amongst the yachtracing fraternity.

However, the greatest advance of Chinese sails was to pass from the basic square sail to the fore-and-aft rig (which enables one to sail into the wind) using a lug sail. This is the sail which everyone has seen in pictures of Chinese junks (see Plates 141 and 142 (pages 205 and opposite)). It has been said that the batten-strengthened lug sail of the Chinese junk is the finest sail ever invented. A modern version of it is the gaff sail; the forward edge (called 'luff by mariners) has been pushed back to commence at the mast rather than slightly in front of it.

Modern yachts have a gaff and a 'leg of mutton' or 'Bermuda rig' sail, the latter being more or less the hind half of a lug sail – an upright triangle. It is by no means certain that a modern yacht could outperform a comparable Chinese junk built for racing and using lug sails with battens in the classic manner. A race between two such vessels would be interesting. The junk is the direct ancestor of the yacht, but may still be better.

Fore-and-aft rigs with lug sails must have existed in the second-century AD China: by the third century they are clearly described in the book *Strange Things of the South* by Wan Chen, on ships capable of carrying the staggering amount of 700 people and 260 tons of cargo! Wan Chen describes these ships as having four masts, and says:

The four sails do not face directly forwards, but are set obliquely, and so arranged that they can all be fixed in the same direction (parallel to each other), to receive the wind and to spill it. Those sails which are behind the most windward one receiving the pressure of the wind, throw it from one to the other, so that they all profit from its force. If it is violent, [the sailors] diminish or augment the surface of the sails according to the conditions. This oblique rig, which permits the sails to receive from one another the breath of the wind, obviates the anxiety attendant upon having high masts. Thus these ships sail without avoiding strong winds and dashing waves, by the aid of which they can make great speed.

Another book of 260 AD by K'ang T'ai describes ships with as many as seven masts, used for sailing to Syria. The use of multiple masts was rendered easy and natural in Chinese ships due to the bulkhead construction of their hulls, which have a whole series of obvious crosstimbers capable of providing bases for masts. Wan Chen

makes clear that as early as the third century, the Chinese were already well aware, in the region around Canton, of the best way to avoid one sail being becalmed by another behind it. They positioned the masts not directly in a row along the centre of the ship lengthwise, but staggered thwartwise from one side to the other. This brilliant idea was never adopted in the West; even the fastest Yankee Clippers, of which Europe was once so proud, had the pedantic feature of the masts marching along straight above the keel, so the rear sails becalmed the fore sails.

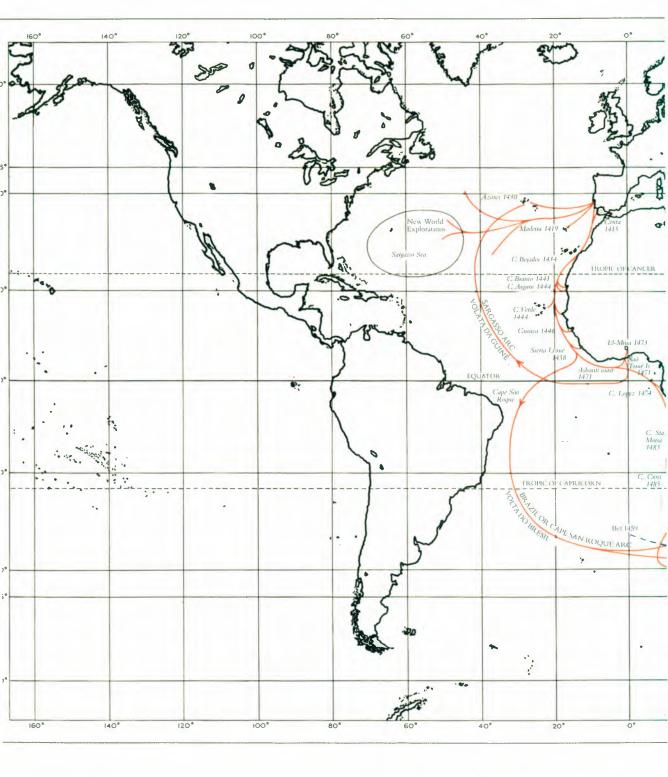

The only way to sail into the wind is by freeing oneself from the fixed notion that a sail must be the traditional square sail whose basic position is at right angles to the boat. It is true that there is a tedious process known as 'wearing', by which square-sailed boats loop round over and over again and slowly creep into the wind. But the only efficient method is what is called 'tacking', and this cannot be done with a square sail.

What is needed in order to tack into the wind is a fore-and-aft rig: a sail whose axis is essentially *along* the long axis of the boat, rather than at right angles to it. On such a rig, the mast is no longer just a long pole holding up the square sail, but becomes a pivot for the sail to swing to one side and then to the other to catch the wind on alternate sides as the ship tacks. This the Chinese did.

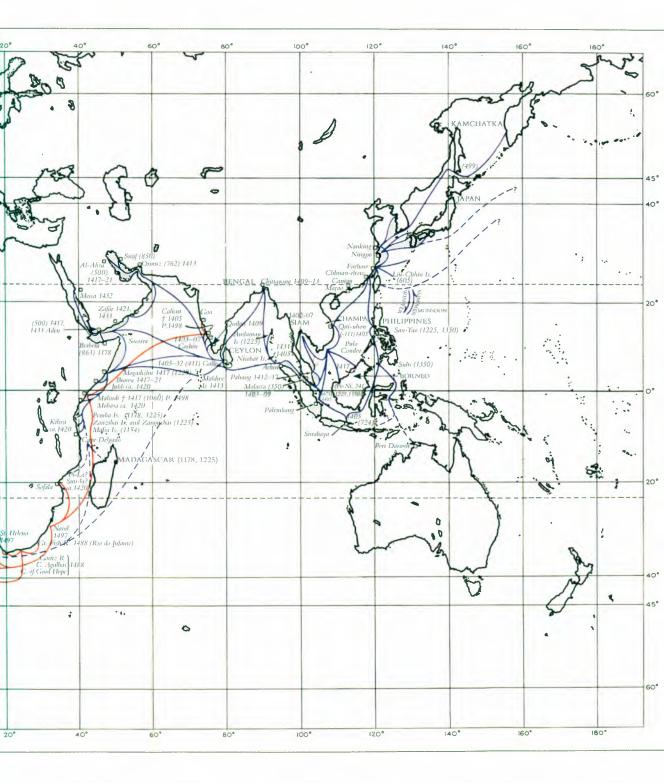

When sailing into the wind, a tacking ship can experience a great deal of leeward drift, blowing the ship too much sideways and making too little progress forward. The Chinese therefore invented the leeboard to prevent this. This is basically a board lowered into the water on the lee side of the ship (opposite the direction of the wind) to exert pressure on the water and prevent drift in that direction; it also helps to hold the ship upright. Sometimes the leeboard would be lowered from a slot in the centre of the ship, in which case it can be called a centre-board.

Leeboards existed in China from at least the eighth century. In a book by Li Ch'üan of 759 AD entitled Manual of the White and Gloomy Planet [of War; Venus], we are told of leeboards on certain warships that they 'held the ships, so that even when wind and wave arise in fury, they are neither driven sideways, nor overturn'. Leeboards did not appear in Europe before about 1570, however, when they were adopted by the Dutch and Portuguese who were then trading with China.

When Europeans eventually made their way to China and saw the Chinese ships, with their many masts

ABOVE (143) This elaborate map of sea voyages was prepared under the personal supervision of Joseph Needham, on the basis of many years of research. The red lines show fifteenth-century Portuguese voyages (extending as far east as Goa); the blue lines show fifteenth-century Chinese voyages for comparison. When the lines are dotted, it indicates that the voyages are conjectural and not proven. Chinese dates of earliest proven visits to the locations are bracketed if they are taken from textual evidence prior to the fifteenth century. The two blue lines emanating out into the Pacific Ocean and ending in question marks represent the unknown fates of convoy voyages heading in the direction of America, which never returned. Needham wrote an entire book on the subject of trans-Pacific sea contacts, and believed that it was possible that the Chinese had reached America more than once but were unable to return home and were thus essentially marooned, leading to possible cultural influence on ancient American civilisations.

Although the pre-European Chinese voyage to Port Darwin in Australia is shown as conjectural for lack of conclusive proof, Needham was firmly of the opinion that it had occurred and that it was the Chinese who had 'discovered Australia'. Such vast quantities of Chinese pottery have been found littering the East African coast that East Africa has been proven to be a frequent and routine trade destination for the Chinese, and African giraffes were even transported back to the Emperor for his private zoo, and Chinese paintings of them survive. The Chinese sailed as far north-west as Arabia and many centuries earlier even had an ambassador resident at Rome (on which the sinologist Homer Dubs wrote an entire book). Chinese trade with the whole of South-east Asia, India, Ceylou, and the Philippines was frequent and routine, supplying the Chinese with exotic products of the south, such as spices, colourful feathers, tropical wood, Burmese jade, strange fruits, vegetables and plants.

and their fore-and-aft rigs, they were immensely impressed. The first attempt to copy what they saw was the adoption in Europe of multiple masts on ships, with square sails on the fore masts but a fore-and-aft rig for the mizzen mast at the rear of the ship. Since the Arab lateen sail was ready to hand, it was the lateen which was fitted to the mizzen of the European three-masters commencing about 1304, not long after Marco Polo's time in China. But the idea was slow to be assimilated, and only a couple of centuries later did such ships really come into their own.

In 1492 Christopher Columbus sailed such a ship to America. All the Western three-masters of the sixteenth and seventeenth centuries carried lateen sails aft. After that, the more efficient gaff sail replaced the lateen on the mizzen mast of European vessels. The actual Chinese lug sail apparently did not make an appearance there before the sixteenth century in the Adriatic. Certain traditional Venetian boats with lug sails appear to be direct copies of Chinese vessels in other respects as well, having nearly flat bottoms and enormous Chinese-style rudders.

The nautical historian H. Warington Smyth said that these Venetian craft are 'one of the finest forms of seagoing lugger in the world'. They are thought to have derived from designs of Chinese ships brought back by Marco Polo and his Italian peers. But the luggers remained regional, the main line of European development taking the idea of the Chinese ship rather than the design. This was undoubtedly a mistake, for the great European sailing ships were truly inefficient compared to sea-going junks, of which Smyth had this to say: 'As an engine for carrying man and his commerce upon the high and stormy seas as well as on vast inland waterways, it is doubtful if any class of vessel is more suited or better adapted to its purpose than the Chinese junk, and it is certain that for flatness of sail and for handiness, the Chinese rig is unsurpassed.' Needham adds: 'The Chinese balance lug ranks indeed among

RIGHT (144) An illustration of a small Chinese fighting ship of the Ming Dynasty or earlier, published about 1700. The wood block for the plate probably dates from at least 1500, and must have appeared in earlier printings. Mid-battle, one man is shooting an arrow as others fight on deck with swords or spears. Particularly clear are the bamboo mat sails with their battens, which could be raised or lowered like blinds according to the wind, work unimpeded by holes, and were so aerodynamically efficient that the little attack boats could manoeuvre round the bigger ships like swooping swallows. It was for lack of such battens that Western ships were so inferior, partially because of the unavailability of bamboo in the West (no suitable material for battens was ready to hand, and battens were therefore never thought of). (Collection of Robert Temple.)

the foremost achievements in man's use of wind power.'

It is probably a lack of bamboo for battens which held back the adoption of the lug sail in Europe except in small localities like the Adriatic, or amongst the Portuguese on their *lorchas* of the sixteenth century. The Chinese stimulus to European sailing was therefore not as powerful as it might have been if direct copying had taken place in rigs, and with masts. But in summing up the situation, it might be well to quote the views of another nautical historian, G.S. Laird Clowes:

In 1400 AD northern ships were entirely dependent on a fair wind, and were quite unable, indeed never attempted, to make headway against an adverse one. Before 1500 AD European ships had been able to make the long ocean voyages which had resulted in Columbus' discovery of America, Dias' doubling of the Cape of Good Hope, and the opening of the Indian Ocean trade route by Vasco da Gama. Other scientific advances, such as the introduction of the mariner's compass from China, bore their part in making such voyages possible, but without the far-reaching improvements in masts and sails the great discoverers could never have accomplished their work.

LEFT (145) A junk under repair in dry dock in Hong Kong. Four or five transverse bulkheads can be seen inside the ship and various ribs or frames are also visible. The habit of building hulls like this meant that watertight compartments were possible. If a leak occurred in one section, it could be sealed off from the rest and the ship remained afloat. Chinese ships had watertight compartments from at least the second century AD, but the idea only caught on in the West at the end of the eighteenth century. (Waters Collection, National Maritime Museum, London.)

After a gap of at least 1300 years, Europeans thus adopted Chinese concepts of rigging. In every way, whether for navigation, propulsion, or steering, Europeans were dependent upon Chinese ideas in order to be capable of the Great Voyages of Discovery. The great colonial powers of the West, the Portuguese, British, French, and other Empires, were the direct result of the adoption by Europeans of Chinese technology on the high seas.

# WATERTIGHT COMPARTMENTS IN SHIPS

SECOND CENTURY AD

From at least the second century AD, if a traditional Chinese ship received a hole of any kind in its hull, the ship would not sink. This is because the Chinese constructed hulls on the bulkhead principle. A bulkhead is an upright partition separating compartments. A typical medium-sized freighter had fifteen bulk-heads and thirty-seven rib frames. What would happen would merely be that one of the sixteen bulkhead compartments would flood, but the other fifteen, being sealed off from it, would remain dry and the ship would continue to float. There is no way of ascertaining how many thousands of lives would have been saved if Western ships had been built on such sensible principles; but they were not.

Just how novel this technique was only 200 years ago may be seen from a letter written in 1787 by Benjamin Franklin about the mail packets which were envisaged between the United States and France: 'As these vessels are not to be laden with goods, their holds may without inconvenience be divided into separate apartments, after the Chinese manner, and each of these apartments caulked tight so as to keep out water.'

The idea of watertight compartments for ships' hulls was brought to Europe from China by Sir Samuel Bentham (1757–1831), long-time chief engineer and architect of the British Navy. As a young man in 1782, he travelled through Siberia to China and studied Chinese ship construction. He campaigned in Europe for bulkheads, so that by 1795 the Lords Commissioners of the Admiralty asked him to design and build six sailing ships of a new design with 'partitions contributing to strength, and securing the ship against foundering, as practised by the Chinese of the present day'.

As late as 1824, naval writers were still breathlessly expostulating upon the miracle of this simple technique. In that year, a report in Mechanics' Magazine stated: 'There is a method of making it almost impossible to sink ships which ... is now employed by the Chinese. The hold is divided into a number of compartments, so that if the ship spring a leak, or her sides are stove in, she will remain afloat.'

What is surprising is that these ideas were clearly described by Marco Polo in 1295, but no one paid any attention. They were repeated in 1444 by Nicolo de Conti in his own *Travels*, where he said: 'These Shippes are made with Chambers, after such a sorte, that if one of them should breake, the others may goe and finish the Voyage.' But so conservative were European shipbuilders and sailors that it took 500 years after the principles of watertight compartments were made known to the West for them to be adopted.

A small exception to this must be mentioned. In about 1712, some English fishermen adopted the Chinese principle of a sealed hull compartment which could be free-flooded under controlled conditions (recorded in a Chinese text of the fifth century AD and doubtless much earlier than that). The purpose of this 'wet-well' in a ship called a 'wellsmack' was to enable fishermen to bring their fish to port fresh, still swimming in water. This is a traditional Chinese practice. In China, such free-flooding compartments were also used to raise and lower the level of a boat when shooting rapids in rivers, giving the captain control over the amount of waterresistance of his ship by acquiring and discharging water ballast. The flooded compartments would be emptied by bilge pumps using the square-pallet chain-pump design, which the British Navy also adopted directly from the Chinese.

The bulkhead construction of ship hulls was a natural notion which the Chinese derived from copying the bamboo, which has transverse septa dividing the stem into a series of compartments. Since Europe did not have bamboo, this inspiration was not to hand.

The use of bulkheads afforded an obvious multiplicity of strong cross-timbers in the hull capable of receiving masts. This not surprisingly resulted in the adoption of multiple masts in Chinese ships, which caused such amazement to Westerners in medieval times and led to the adoption of multiple masts in Europe.

A highly conservative estimate for the adoption of transverse bulkheads in Chinese ship hulls would be the second century AD. Although rafts and coracles were in profuse use at that time, there is no reason to believe that proper ships did not exist before then, whose bulkheads were effectively watertight (if not by design, then at least as a result of the way the hulls were constructed). The bulkhead construction principle may therefore be much older.

# THE HELICOPTER ROTOR AND THE PROPELLER

FOURTH CENTURY AD

A description of a helicopter top dating from the fourth century AD was mentioned by the philosopher and alchemist Ko Hung (see the account of manned flight with kites, page 191). By then, helicopter tops seem to have been common toys in China, one of the names most generally used for them being 'bamboo dragonfly'. The top was an axis with a cord wound round it, and with blades sticking out from the axis and set at an angle. One pulled the cord, and the top went climbing up into the air. This simple but fundamental toy had a very important effect on the European pioneers of aviation.

Sir George Cayley, the father of modern aeronautics, studied the Chinese helicopter top in 1809. It had two sets of rotor blades (using feathers, in this case), and a winding device using a spring. This Chinese 'bamboo dragonfly' could rise 20–25 feet in the air. Cayley set about trying to make an improved version. His drawings of 1853 portray his own helicopter top, which could mount 90 feet in the air. Encountering the Chinese helicopter top in 1792 (by way of two Frenchmen, Launoy and Bienvenu) had stimulated Cayley to take an interest in the possibilities of aviation in the first place.

The helicopter top was the model for what became the propeller of modern aircraft. But the Chinese had also preceded Europe in vertically mounting these rotors, as was necessary for use in airplanes. Early in the seventeenth century, kite-flying was temporarily banned in China. Liu T'ung tells us in his book of that time, Descriptions of Things and Customs at the Imperial Capital, that people turned instead to vertically mounted 'wind-wheels', which amused people by their pretty red and green colours, which flashed rapidly as the wheels turned in the wind. The wind-wheel could be either set stationary or carried in the hand on sticks. There were also pinwheel varieties, which were able to perform work by depressing a lever and beating a drum. Some of the Chinese wind-wheels may be seen in a painting made in 1310 by Wang Chen-P'eng. We also know of wind-wheels being attached to cambered kites, set vertically mounted, but spinning in the wind 'just for joy'. The Chinese were thus amusing themselves with actual miniature airplanes with proper airfoil wings and propellers, but merely letting them flit about in the wind. There is no record of their having

attempted to harness a power source to the propeller and make the kite fly by becoming a real airplane. Thus, the Chinese invention of the helicopter top led in China to nothing but amusement and pleasure. But its influence in the West 1400 years later was to be one of the key elements in the birth of modern aeronautics and manned flight.

# THE PADDLE-WHEEL BOAT FIFTH CENTURY AD

The idea of the paddle-wheel boat did apparently occur to one early European inventor, though it seems never to have been constructed, and involved a

very unwieldy power source. An anonymous manuscript entitled *De Rebus Bellicus*, which is thought to date from the late fourth century, contains the suggested design for a ship with three pairs of paddle wheels powered by six oxen walking round and round on the deck, as in grinding a mill. It is considered unlikely that the vessel existed, but we must acknowledge that as far as the paddle-wheel boat is concerned, the original idea seems to have been European, but the first execution Chinese, with no connection between the two. In Europe, therefore, the idea led to nothing, while in China it led to the building of hundreds or thousands of ships.

The first record of the existence of paddle-wheel boats occurs in a Chinese account of a naval action

under the command of Wang Chen-O, one of the admirals of the Liu Sung Dynasty, in 418 AD. This is described in *The History of the Southern Dynasties* (compiled in 670):

Ming Dynasty paddle-wheel battleship dates from about 1500. but this printing comes from the 1883 Beijing publication Strategy for Governing the Country, which specifically states that it re-used ancient woodblocks that had been carefully stored by the imperial authorities. If the match for the steam-powered ones of the British Navy, it is no wonder that they suffered such lumiliation in battle. In any case, these no longer even existed, but wheeler the Climese were still building by that time was one in stone (see Plate 147 (page Robert Temple.)

ABOVE (147) The Empress-Dowager Tz'u-Hsi built this folly in 1889 in the pleasure-gardens of the Summer Palace near Peking. It is a marble boat with paddle wheels on each side. Paddle-wheel boats were invented in China in the fifth century AD. By the twelfth century they had reached lengths of 300 feet, and could carry eight hundred men. Some at that time had as many as ten separate decks.

Wang Chen-O's forces sailed in covered swooping assault craft and small war-junks. The men propelling the boats were all hidden inside the vessels. The Ch'iang [barbarians] saw the ships advancing up the Wei [river] but could not see anyone on board making them move. As the northerners had never encountered such boats before, every one of them was sore afraid, and thought that it was the work of spirits.

An improved version was made by Tsu Ch'ung-Chih between 494 and 497. His boat was called the 'thousand-league boat', and was tested on the Hsin-T'ing river, south of modern Nanking. It could travel enormous distances in a single day without the aid of wind, and must have represented a considerable refinement of the earlier designs.

An admiral of the Liang Dynasty, Hsü Shih-P'u, used a number of paddle-wheel boats in his campaign against the rebel Hou Ching in 552. His paddle-wheel boats were called 'water-wheel boats'. And in another campaign against the same rebel, the admiral Wang Seng-Pien is described as having in his fleet 'ships which had two dragons on the sides to enable them to go very fast'. The text is thought to have become confused, and originally to have stated 'two wheels'. And at the siege of Li-Yang in 573, another admiral, Huang Fa-Ch'iu, who was also a distinguished military engineer, built and used a number of 'foot-boats', which were obviously paddle-wheelers operated by foot treadles.

Between 782 and 785, Li Kao, prince of T'ang, was Governor of Hungchow. The official history of the time tells us that:

Li Kao, always eager about ingenious machines, caused naval vessels to be constructed, each of which had two wheels attached to the side of the boat, and made to revolve by treadmills. These ships moved like the wind, raising waves as if sails were set. As for the method of construction it was simple and robust so that the boats did not wear out.

We are also told of these ships that their speed was 'faster than a charging horse'.

During the medieval Sung Dynasty the paddlewheel warships really came into their own. They were often rudderless and manoeuvred swiftly and with breathtaking agility by means of a complex system of using varying combinations of their paddle wheels – perhaps three out of six on one side, then two on the other, and so on. They were able to dart in and out between other ships and wreak great havoc. Some of them had rammers fitted to their prows.

The admiral Shih Cheng-Chih in 1168 is recorded as having constructed a 100-ton warship propelled by a single twelve-bladed wheel. This means that some of the paddle-wheel boats were stern-wheelers. And when boats are described, as they often were, as having odd numbers of wheels, one would have been at the stern and the others in opposite pair formation along the sides. However, even though the wheels would have been opposite each other, they would almost certainly have worked quite independently, so that one could stop and the opposite one rotate. This seems to have been the method of steering.

We have an account from 1130 of the construction of some naval paddle-wheel ships:

Kao Hsüan, who had formerly been Chief Carpenter of the Yellow River Naval Guard Force, and of the Pai-p'o Vehicular Transport Bureau of the Directorate of Waterways, submitted a specification for wheeled ships which he claimed could cope with the enemy.... He first built an eight-wheel boat as a model, completing it in a few days. Men were ordered to pedal the wheels of this boat up and down the river; it proved speedy and easy to handle whether going forwards or backwards. It had planks on both sides to protect the wheels so that they themselves were not visible. Seeing the boat move by itself like a dragon, onlookers thought it miraculous.

Gradually the number and size of the wheels were increased until large ships were built which had twenty to twenty-three wheels and could carry two or three hundred men. The pirate boats, being small, could not withstand them.

By this time, the paddle-wheelers came to be called 'wheel ships', and the terminological confusion which had existed for several centuries, when a wide variety of colourful names were used for them, settled down to a standard term. Technological improvements on the 'wheel ships' went on apace. Not long afterwards, Ch'eng Ch'ang-Yü constructed 'wheel ships' up to 300 feet long, capable of carrying between seven and eight hundred men!

The rebels ('enemies') mentioned above captured some of the 'wheel ships', together with the engineer Kao Hsüan. Thus commenced an arms race, with the rebels for a time building bigger and better 'wheel ships' than the Southern Sung Dynasty against which they were in revolt. As we are told in a contemporary history, 'Within two months the pirate bases had over ten many-decked wheel ships that were stronger and better constructed than the government ships.'

At the height of the conflict, the rebel fleet had several hundred 'wheel ships' of this type in operation. It must be emphasized that these ships were quite unsuitable for sea operations, and all the naval engagements took place on rivers and lakes. At a later period of history, under the Mongol Dynasty, when naval operations concerned the sea rather than inland waters, the use of paddle-wheelers went into serious decline. But at the culmination of the Sung period's conflict with the rebels in the twelfth century, paddle-wheelers reached what was probably their most extreme form.

The imperial forces in their turn imitated the paddle-wheel ships of the rebels but made them larger - as much as 360 feet in length, 41 feet in the beam, and with masts 72½ feet high. The largest number of men on record for working treadles on a 'wheel boat' is two hundred. Needham believes that the medieval paddle-wheelers of the Chinese could generate 50 horsepower and would have averaged a speed between 3½ and 4 knots. After this time, paddle-wheelers diminished in size, and also in importance. But they were still around until modern times, and saw naval action against the British in 1841 during the Opium Wars. The British believed them to be rapidly constructed copies of the British Navy's own paddlewheelers, unaware that the Chinese had been using such ships for sixteen centuries by that time. Indeed, as recently as 1929, paddle-wheelers were still in use for carrying passengers up and down the Pearl River near Canton, though none is known to survive.

#### LAND SAILING

SIXTH CENTURY AD

Land sailing, particularly on beaches, has become a popular sport today in the West. It originated in sixth-century China. About 550 AD, the Liang Emperor Luan (552-4), a Taoist scholar, wrote his *Book of the Golden Hall Master*. In it he recorded:

Kaots'ang Wu-Shu succeeded in making a wind-driven carriage which could carry thirty men, and in a single day could travel several hundred *li* [hundreds of miles].

These developments continued, and we have the following account, from a book called Continuation of the New Discourses on the Talk of the Times, of a very large vehicle built for the Emperor Yang of the Sui Dynasty about 610. It is thought that the account, though obviously exaggerated, describes a genuine sailing vehicle, or at least a vehicle whose progress was significantly assisted by sails, whatever other form of propulsion or haulage it may also have had:

Yuwen K'ai built for Sui Yang Ti a 'Mobile Wind-Facing Palace'; it carried guards upon its upper deck, and there was room for several hundred persons to circulate in it. Below there were wheels and axles, and when pushed along it moved quite easily as if by the help of spirits. Among those who saw it there was no one who was not amazed.

One notices that the vehicle was *pushed along* by some normal means, and sails fitted to the vehicle rendered it astonishingly light, so that this was a semi-sailing carriage, or sail-aided carriage. Such assistance from sails in later times even came to be applied to ploughs. It must have made quite a sight to have farmers going up and down their fields with their ploughs pulled by wind power. But this always seems to have been something of a rarity, unlike the commonplace nature of sailing wheelbarrows.

The Chinese invented the wheelbarrow by the first century BC (page 95). At some unknown time after the first application of the sail to land travel, as just described, sails were put onto wheelbarrows. A.E. van Braam Houckgeest inspected a native Chinese sailing wheelbarrow closely and did a careful drawing of one, which he published in 1798 in his book An Authentic Account of the Embassy of the Dutch East-India Company to the Court of the Emperor of China in the Years 1794 and 1795. It has the batten sails and multiple sheets which were so characteristic of Chinese ships.

Sailing wheelbarrows, known as sailing carriages to Western visitors, caused a sensation in the West when they became known to the public, from the sixteenth century. From that date for about two centuries, an imaginary view of a sailing carriage

ABOVE (148) 'Flora's Wagon of Idiots' by Hendrik Gerritszoon Pot (1585–1657). This painting is loosely copied from an earlier engraving by Chrispijn van de Passe, but there were many such pictures at this time showing the sailing wagons introduced into Europe from China by Simon Stevin. This painting is satirical in intent, attacking the wave of mass hysteria which swept over Holland at this time and which has gone down in history as 'tulipomania' — one of the strangest phenomena in European history, when there was such excitement over tulips that people would commit murder to get the bulbs. (Franz Halsmuseum, Haarlem.)

was drawn on nearly every atlas map which showed China. Milton even mentioned them in *Paradise Lost* in 1665, speaking 'Of Sericana, where Chineses drive With Sails and Wind their canie Waggons light' (III, 431).

Jan Huyghen van Linschoten in his *Itinerario* of 1598 wrote:

The men of China are great and cunning workemen, as may well bee scene by the Workmanship that commeth from thence. They make and use (waggons or) cartes with sayles (like Boates) and with wheeles so subtilly made, that being in the Fielde they goe and are driven forwards by the Winde as if they were in the Water....

Less frequently seen, since they were in less accessible localities, were the Chinese ice-yachts, which ran along the ice on wheels by sail power. Contemporary

ice-yachts were in use in 1935 on the Liao River, near Ying-k'ou in the cold region of Manchuria.

The great Dutch scientist and mathematician Simon Stevin actually constructed a Chinese sailing carriage in the autumn of 1600. Stevin was deeply influenced by Chinese science, and helped to transmit to the West the Chinese inventions of decimal fractions and equal temperament in music (see pages 157 and 234). Stevin's land-sailer carried Prince Maurice of Nassau, the young scholar Grotius and many dignitaries along a beach at great speed. It covered a distance of nearly 60 miles in less than 2 hours, so that its average speed was 30 miles per hour, and it must have reached 40. This gave Europeans their very first taste of real speed, and is thought to have exerted a profound psychological effect which lasted in various subtle ways and helped prepare for the 'modern age'. We are fortunate to have a vivid description, written six years later, by Gassendi:

RIGHT (149) Land sailing was being practised in China from the sixth century AD. The most useful form of it was in the attachment of a sail to a wheelbarrow, so that the wind took part of the load. Here we see an engraving from A.E. van Braam Houckgeest's book of 1797, An Authentic Account of the Embassy of the Dutch East-India Company to ... China. The sail is a batten sail with multiple sheets (rigging), of the sort used on Chinese junks. The wheelbarrow is of the typical Chinese form with a central wheel, which can carry far greater loads than Western forms. Also he stept aside to Scheveling, to make triall of the carriage and swiftnesse of the waggon, which some yeers before was made with such Art, that it would run swiftly with sails upon the

land, as a ship does in the sea. For he had heard how Grave Maurice, after the victory at Nieuport, for triall sake, got up into it, with Don

Francisco Mendoza taken in the fight, and within two hours was carried to Putten which was 54 miles from Scheveling. He therefore would needs try the same, and was wont to tell us, how he was amazed, when being driven by a very strong gale of wind, yet he perceived it not (for he went as quick as the wind), and when he saw how they flew over the ditches he met with, and skimmed along upon the surface only, of standing waters which were frequently in the way; how men which ran before seemed to run backwards, and how places which seemed an huge way off, were passed by almost in a moment; and some other such like passages.

#### THE CANAL POUND-LOCK

TENTH CENTURY AD

Everyone who has seen a modern canal will be familiar with the pound-lock. It has two gates. The boat enters by one, which closes behind it. The water level in the lock then either rises or falls to match the level of the water towards which the boat is sailing. When it has done so, the further gate opens and lets the boat through. The first certain date for a poundlock in Europe is 1373.

The canal pound-lock was invented in China in 984 AD. The inventor was Ch'iao Wei-Yo, who, in 983, had been appointed Assistant Commissioner of Transport for Huainan. The impetus for his invention

was a concern over the enormous amounts of grain which were being stolen during canal transport at that time. Grain was the normal tax payment throughout China's history. Movement of the grain to central repositories and warehouses was the lifeblood of the Empire, and therefore any substantial interruption of this process was a very serious social and political problem.

Until 984, boats could only move between lower and higher water levels in canals over double slipways. Chinese boats had no keels, and were nearly flatbottomed. A form of portage had been developed in China, therefore, whereby spillways originally designed to regulate water flow were elongated in gentle ramps both front and back, leading into the water. A boat would come along and be attached to ropes turned by ox-powered capstans. Within two or three minutes, the boat would be hauled up a ramp to the higher level, and for a moment would balance precariously in the air. Then it would shoot forward like an arrow out of a bow and scud along the canal at a level several feet higher than it had started. Passengers and crew had to lash themselves tightly to the boat to avoid being hurled into the air and injured. The great disadvantage of this ingenious technique was that boats often split apart or were seriously damaged by the wear and tear of being dragged up the stone ramps. Whenever a boat broke up on a ramp, the contents would promptly be stolen by organized gangs - including corrupt officials - who waited for just such an occurrence. Sometimes, apparently, the

ships were roughly handled on purpose, or were artificially weakened or had even been chosen for their weaknesses so that an 'accident' of this kind could be brought about intentionally.

Ch'iao Wei-Yo was determined to wipe out this practice. He therefore invented the pound-lock so that double slipways would not be needed. Here is how the official history of the time relates the story:

Ch'iao Wei-Yo therefore first ordered the construction of two gates at the third dam along the West River (near Huai-yin). The distance between the two gates was rather more than 50 paces [250 feet], and the whole space was covered over with a great roof like a shed. The gates were 'hanging gates'; when they were closed the water accumulated like a tide until the required level was reached, and then when the time came it was allowed to flow out.

He also built a horizontal bridge between the banks, and added dykes of earth with stone revetments to protect their foundations. After this was done to all the double slipways the previous corruption was completely eliminated, and the passage of the boats went on without the slightest impediment.

Pound-locks made true summit canals possible. Water levels could differ by 4 or 5 feet at each lock without any problem at all. Over a stretch of territory, therefore, a canal could rise more than 100 feet above

sea level, as was the case with the Grand Canal for instance (rising 138 feet above sea level). This made possible a vast extension of the canal network and freed hydraulic engineers from many awkward topographical restrictions. Pound-locks were fitted into the Magic Canal (page 198) by the tenth or eleventh century.

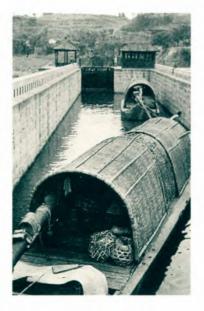

The use of pound-locks meant that precious water could be saved. Many of the Chinese canals went dry in the summer, and days might have to pass before enough water had accumulated from the length of a canal for a flash-gate to be opened to let boats through. There

could be hundreds of boats waiting at any given gate. But with the pound-lock, only the one lockful of water was used each time. This meant that the canals, by saving water, could extend the months of their usefulness. Also, Shen Kua tells us in his *Dream Pool Essays* of 1086 of a single canal:

It was found that the work of 500 labourers was saved each year, and miscellaneous expenditure amounting to 1,250,000 cash as well. With the old method of hauling the boats over, burdens of not more than 21 tons of rice per vessel could be transported, but after the double gates were completed, boats carrying 28 tons were brought into use, and later on the cargo weights increased more and more. Nowadays Government boats carry up to 49 tons, and private boats as much as 800 bags weighing 113 tons.

Pound-lock gates later went largely out of use in China, owing to social changes. The Mongols shifted the capital to Peking, making it impossible for the whole of the imperial grain tribute to be transported by canal. Much of the transport of grain was shifted to the sea routes – sometimes more than half of the entire annual grain supplies. As time went on, the need for large barges on the canals diminished, a larger number of smaller vessels came into use, and the pound-locks were allowed to fall into disrepair and eventual decay. By the time the Chinese pound-lock found its way to Europe, it was on the wane in

its country of origin, and the fact that it came from China was increasingly easy for not only Europeans but for the Chinese themselves to forget.

LEFT (150) A photograph taken by Cecil Beaton during the Second World War, showing two Chinese sampans in a modern pound-lock. The pound-lock was invented by Ch'iao Wei-Yo in 984 AD, but the first European one was not constructed until 1373 at Vreeswijk in Holland, at a point where the canal from Utrecht joined the River Lek. Shortly afterwards, another was built at Spaarndam. The idea must have been brought from China to Holland by Dutch traders.

### THE LARGE TUNED BELL

SIXTH CENTURY BC

The Chinese invented, developed and perfected tuned bells long before anyone else. Indeed, they went on to base their entire system of measurements - length, width, weight, volume - on musical pitches of tuned bells. At first, bells were just noise-making instruments. But by the sixth century BC at the latest, and probably long before, finely tuned bells were being manufactured, which when struck emitted precise notes.

The bell seems to have originated from metal grain measures. It evolved into two forms of hand bell - the to, which faced upwards, and the chung, which faced downwards, and the latter became the basis for Chinese measurements. The ancient book, Kuo Yii, dating from several centuries BC, states that:

The ancient kings made as their standard the chung vessel, and decreed that the magnitude of its pitch should not exceed that produced also by the string of the chiin [7-foot tuner], and that its weight should not exceed 120 catties. The measures of pitch, length, capacity, and weight originate in this standard vessel.

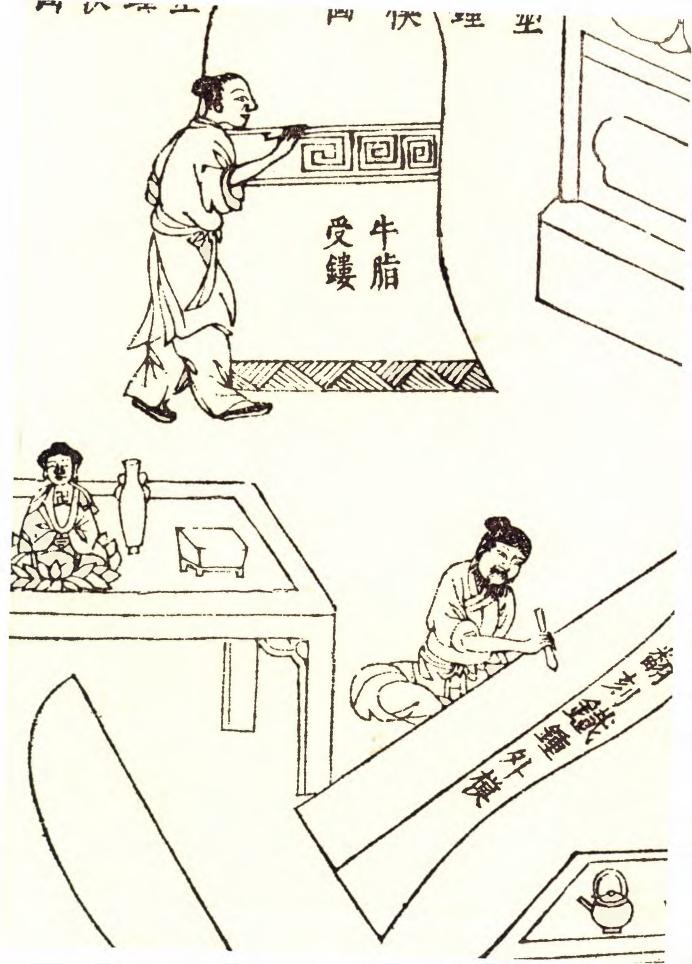

It is doubtful if any other civilization in history based all its measurements on the musical pitches of bells. This system certainly gave an impetus to the development and perfection of the tuned bell in China, since if perfectly tuned bells did not exist, then all would fall into confusion. No standards of measure would exist, cheating and corruption would spread, commercial disagreements could not be avoided, the disruption of trade would ensue, and riots and rebellions might follow. These were real, not imagined dangers. It was imperative that the authorities kept the measures in order by regulating the pitches of the bells. This was one of the most urgent concerns of all ancient Chinese governments. The very safety of the state might have been at stake.

The way in which pitches of bells were transformed into standard measures of length was by way of the duin, a stringed tuner 7 feet long. The pitch of the bell would be matched by tuning of the string, which would then be measured, giving a specific length. (Strings composed of identical material and under the same tension give out different notes when plucked according to their different lengths. A sliding bridge may be moved along under a string to alter its effective length when plucked, the resulting length being precisely measurable.) This process could then be reversed, so that a standard length given by a bell at the capital could give the pitch of a string of a duin in a distant city, which could then be matched by a bell cast there. The Chinese divided the octave into twelve notes. Consequently, there came to be official sets of twelve bells giving out these fundamental notes, and from them all other instruments would be tuned. Also, at the beginning of any piece of music, the appropriate bell would be sounded to give the key.

OPPOSITE (151) The casting of a giant timed bell. The man in the foreground is working on one half of the mould, the other half lying bottom left. The bell which has emerged from this mould is being burmshed in the background. This illustration comes from The Creations of Nature and Man (T'ien-kung K'ai-Wii) of 1637. Its text says: For casting iron bells without the expenditure of too much fat and wax, an outer layer of the mould is first made from earth, which is then cut into two sections either longitudinally or crosswise. Dowel pins are used to insure the positive alignment of these two sections when the mould is closed.... After the words are engraved, the surface is spread over with a thin layer of ox fat, so that later the bell casting will not stick to the mould. The cope is then laid over the core, and the separate sections are sealed together with mud. The mould is then ready for casting! (Chinese text translated by Sun E-Tu Zen and Sun Shiou-chuan.)

At first the bells did not have clappers and had to be struck to give out their notes. Chinese clapperless bells date from about the sixth century BC. These would have been struck to give the note which would then be the keynote of the musical scale for an orchestra. In music, ancient Chinese bells seem to have been used to stop and start performances, rather than as actual instruments. They essentially served as ancient tuning-forks.

One of the extraordinary features of most ancient Chinese bells is that they were constructed so as to give out not only one note, but two. If struck in the centre they would give out one note, and if struck to one side, near the edge, they would give out another. The intervals between the notes included major and minor seconds, thirds and fourths, and minor sixths.

After some time, the set of twelve bells came often to be replaced by a set of twelve pitch-pipes, which served the same purpose and were much easier to construct. Using pitch-pipes, it was also possible to extend the measures of capacity and volume. The bells had always given measures of grain, having, after all, originated as grain-scoops. But now pitch-pipes were closely studied and the precise number of grains of millet which would fit into them were counted. An imperial history for the first century BC reveals how 'The basis of the linear measure is the length of the *Huang-chung* pitch-pipe [which gave the fundamental note]. Using grains of medium-sized black millet the length of *Huang-chung* is 90 *fen*, one *fen* being equal to the width of a grain of millet.... Using grains of medium-sized millet twelve

hundred grains fill its tube....The contents of one *Huang-chung* tube, i.e., twelve hundred grains of millet, weigh 12 *chu* [half an ounce].'

As Needham has remarked, this was a clever system, for though 'millet-grains might vary individually, when large numbers of one given species were used a fairly consistent average would be struck (large and small grains aberrant in size being rejected). This method of ensuring against the loss of standard measures was probably as practical as any that could have been devised.'

The achievement of the ancient Chinese with regard to bells was a truly remarkable feat of early technology. Even today, the proper tuning of bells is considered difficult and highly intricate. To manufacture a bell giving

BELOW (152) The largest set of ancient chime bells ever found in China. It was excavated in 1978 at Sui Hsian in northern Hupei Province, from the tomb of Marquess Yi of the State of Cheng, who was buried in the late fifth century BC. Sixty-four bronze bells make up the chime set, which is mounted on wooden beams with bronze supports and fittings, and stood intact in the tomb for 2400 years. The bases and warrior figures included in the supports together weigh over 150 pounds. The largest of the bells alone weighs over 100 pounds. It is believed that five performers were needed to play the set. As for the notes of the bells, forty-seven of them produce two notes with major third intervals, and sixteen produce two notes with major third intervals. Each bell bears a lengthy and meticulous inscription describing precisely what notes it gives forth, how they fit into a scale, and how that scale relates to other scales employed by other feudal states of the period. (Hupei Provincial Museum, Wuhan.)

RIGHT (153) A large bell dating from the fifth century BC. It was cast to give two precise musical notes; it would give out one if struck in the centre, and another if struck on one side, near the edge. Bells like this are generally about 8 feet high, and some are much larger. However, as late as 1000 AD, no bell more than 2 feet high had been seen or heard in Europe. Western church bells are thus essentially an idea imported from China. (Victoria and Albert Museum, London.)

out a particular sound, one must consider the proportions of metals in the alloy, the elasticity and thickness of the material, the specific gravity, the diameters at different points, the contours of the curves, the temperature at which the alloy stands when it is poured, the rate at which it cools,

and so on. Even when all these things are considered, the resulting sound still may not be right. It is common to have to file bells down in places in order to improve their sounds. Apparently, few ancient Chinese bells show signs of filing. Such was the mastery of bronze and iron casting of the ancient Chinese, that perfect bells were produced at the first attempt.

As late as the year 1000 AD, no bell more than 2 feet high had been seen or heard in Europe. But a cast iron bell precisely dated to 1079 still exists at P'ingting in Shansi, in China, which is four or five times this size. Chinese bronze bells have been excavated which date back to at least the fourteenth century BC. While bells of the sixth century BC were just under 2 feet high, no bell higher than 8 inches seems to be known from any ancient Western civilization.

### TUNED DRUMS

SECOND CENTERY BO

Drums have existed from time immemorial, and are common among most tribal peoples. But the tribal drums are not tuned. The Chinese appear to have been the first to develop tuned drums. For this they used stretched leather hides, and they were doing so by the second century BC at the latest. An ancient treatise on drums survives, entitled *Chieh Ku Lu* ('On the History and Use of Drums'), written by Nan Cho in the year 848 AD, but it has not yet been studied by any scholar.

In the most ancient Chinese music, a prime concern was the regulating of ritual dances and mimes, which by sympathetic magic were thought RIGHT (154) A previously unpublished photograph by Ernst Boerschmann, taken about 1900, showing a huge, ancient dung bell with a scalloped rim. This bell, resting on its side on the earth, bears lengthy inscriptions, but nothing is recorded of them or of the location of the bell, which appears to have been discarded. It is probably one of the countless old bells which now no longer exist, having been melted down as scrap.

to affect the weather, communicate and resonate with the spirit world of the ancestors, and regulate the mood and behavior of the people. Bells were not sufficient to control the movements, and a combination of drums and bells was common. An ancient book, *The Music Record*, written in the first century BC, describes how:

In the ancient times the dancers advanced in ranks, keeping together with perfect precision, like a military unit. The strings, gourds, and reed-tongued organs all waited together for the sound of the tambourines and drums. The music was started by a note from a pacific instrument [drum]. Conclusions were marked by a note from a martial instrument [bell]. These interruptions were controlled by means of the *hsiang* drum. The pace was regulated by means of the *ya* drum.

We can see from this that various kinds of drum served different purposes. And the one which 'started the music' must have been a tuned drum, serving, as a bell had earlier done, to set the key. The tuning must have been very precise in order to satisfy the requirements of the Chinese. However, drums have an appalling timbre. They lack resonant higher harmonics, and it is just as well that their notes cannot linger long, for if they did, only noise and uncomfortable dissonance would be heard. A drum is an instrument fit only for momentary hearing. Perhaps the rapid dying away of the initial drum sound was found more convenient for the beginning of a piece of music than the lingering

resonance of the bell, which may have caused some dissonance with the proceedings of the orchestra.

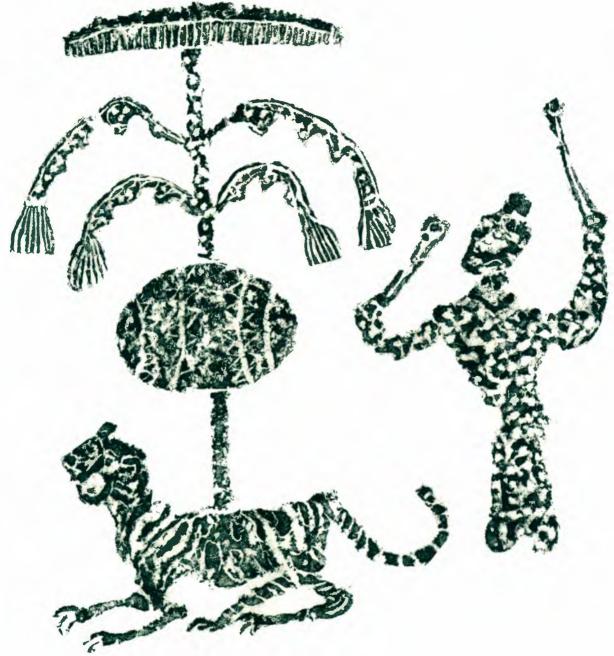

The drum additionally had a solemn and sacred role at one of the great religious state ceremonies of the year. Every 21 December, the drum was used to announce at the winter solstice that the Sun had 'turned round' and begun its advance once more.

Chinese knowledge and understanding of the drum was so advanced that it was used as an analogy of the human eardrum. The Chinese understood that sound was vibration and that it was carried as waves through the air to the ear. As the Taoist T'an Ch'iao wrote in the tenth century: 'An ear is a small hollow.... It is not the ear which listens to sound but sound which of itself makes its way into the ear.' But much earlier, about 742 AD, the earlier Taoist T'ien T'ung-Hsiu wrote about hearing: 'It is like striking a drum with a drumstick. The shape of the drum is possessed in

RIGHT (155)
A previously unpublished photograph by Ernst Boerschmann, taken about 1900. This tuned drum stands outside a Taoist temple and is protected by an ormaniental canopy.

my person in the form of the ear. The sound of a drum is a matter of my responding to it.'

Needham says of this: 'To expand the analogue slightly, it seems that he believed that sounds strike the inner ear, in fact the eardrum, just as drumsticks strike an actual drum; that is to say, they exert pressure. Nevertheless, it is the response of a sentient being which enables one to describe this process as sound.'

T'an Ch'iao even anticipated in a vague way the possibility of sound amplification, for he envisaged this in principle, saying that under certain imagined

circumstances 'even the tiny noises of mosquitoes and flies would be able to reach everywhere.' And his description of the cause of the sound of thunder also came very close to the truth. All this as Needham says, 'is rather remarkable for the tenth century AD'.

ABOVE (157) Large tuned drums hang suspended in a monastery temple, ornamented with swirling patterns based upon the Taoist yin—yang symbol. The temple is at the Derge Gonchen Gompa Monastery of the Sakya school of Tibetan Buddhism (a form of Buddhism especially popular with the Manchu emperors of the Ch'ing Dynasty) in Szechuan Province.

## HERMETICALLY SEALED RESEARCH LABORATORIES

FIRST CENTURY BC

The Chinese preoccupation with musical pitch led to what is probably the strangest of all the protoscientific activities of the ancient Chinese. There is possibly no more bizarre story in China's history than how the world's first attempt at a hermetically sealed research laboratory came about, and what the rationale – or rather irrationale – behind this endeavour was.

In order to explain this properly, we have to understand the concept of ch'i, a word which is essentially untranslatable. Various meanings of ch'i may be conveyed by the following English words: subtle matter, matter-energy, emanation, ether, subtle fluid, rarefied air, aerial or atmospheric disturbance or perturbation, subtle pervasive force, material emanation (such as the 'earthly ch'i' which rose from the Earth), energy present in organized form. The Greek word pneuma bears some resemblance in its meaning to the Chinese concept of ch'i. Similarly, certain mystical uses of the Greek word logos, 'word', resemble the meaning of ch'i, as in the Bible where logos refers to Christ in the sentence: 'The Word was made flesh, and dwelt among us,' in the Gospel of St John.

All living beings inherently possess *ch'i* in addition to their other properties. The Taoists even developed a highly elaborate theory and practice for 'circulating the *ch'i* throughout the human body, which was related to concepts of acupuncture, and was the basis of health and longevity. In the human body, there were particular forms of *ch'i*; there was, for instance the '*ch'i* of the blood'.

It would be possible to continue at great length, but this is sufficient to show that the concept of ch'i was fundamental to the ancient Chinese understanding of nature, life and the cosmos. Different forms of ch'i were conceived of as emanating from just about everyone and everything. If a person influenced another, his ch'i was predominant. Intimately associated with concepts of ch'i were the phenomena of pitch, timbre and resonance. Armies were conceived of as having a peculiar group-ch'i, which was thought of as an energy field floating over their heads, and was sometimes visible as a cloud or haze as they marched into battle. There were no strict cut-off points or boundaries between the spiritual ch'i and physical matter; to the ancient Chinese, not only did the two

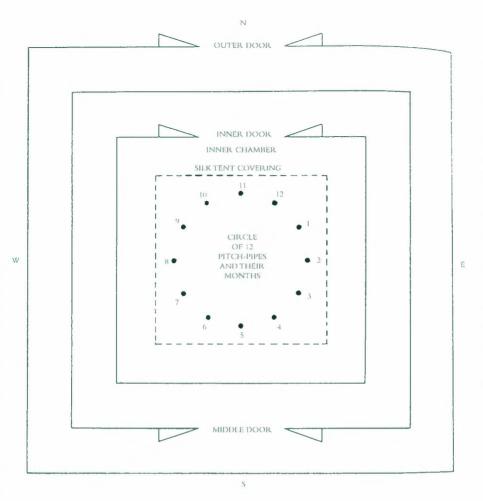

overlap, they intermingled, which gave explanations for countless natural phenomena.

To detect the nature of the group-ch'i of an army, a kind of musical shaman would blow on special pitch pipes, and from the character of the resulting sound would pronounce his conclusions: a note which was weak and did not have sufficient timbre would indicate a weak and vacillating ch'i, and would thus foretell defeat or disaster for the army concerned. Pitch-pipe soundings by shamans were taken for the 'home' army upon its marching off on campaign, and for the opposing army as it stood arrayed for battle in the distance. Sometimes, depending on the musical enquiries of the shaman, a battle would be called off, a retreat ordered, or an immediate attack launched. Music, therefore, was a serious business upon which tens of thousands of lives regularly depended.

The Chinese preoccupation with matters of pitch and timbre became a full-fledged obsession. A dreadful anxiety persisted that somehow the true fundamental pitches might become altered in passage of time or through the loss of certain bells and pipes during civil and military disturbances (which were so frequent throughout China's history); so a custom was instituted to safeguard the pitches which was one of the strangest rituals in history. In order to introduce this peculiar tale, a fairly lengthy quotation from the ancient Taoist book of the philosopher Chuang Tzu (c. 290 BC) sets the scene:

'The breath of the Universe', said Tzu-Ch'i, 'is called wind. At times it is inactive. But when it rises, then from a myriad apertures there issues its excited noise. Have you never listened to its deafening roar? On a bluff in a mountain forest, in the huge trees, 100 spans round, the apertures and orifices are like nostrils, mouths or ears, like beam-sockets, cups, mortars, or pools and puddles. And the wind goes rushing through them, like swirling torrents or singing arrows, bellowing, sousing, trilling, wailing, roaring, purling, whistling in front and echoing behind, now soft with the cool breeze, now shrill with the whirlwind, till the tempest and the apertures are all empty and still. Have you never observed how the trees and branches shake and quiver, twist and twirl?'

Tzu-Yu said, 'The notes of Earth then are simply those which come from its myriad apertures, and the notes of man may be compared

LEFT (FIG. 7) A diagram by Professor Derk Bodde of one of the 'hermetically sealed research laboratories' used from the first century BC onwards to watch for 'blowing of the ashes' under the influence of imaginary earth forces. In order to protect the interior from any possible light, draft or other influence of the elements, an arrangement of imbricated corridors was made, resembling a modern photographic darkroom. One came in by the outer door, walked to the far end of the structure to enter the middle door, and walked to the other end to enter the inner door. Then one entered a tent, inside which were further protective coverings.

to those which issue from tubes of bamboo - allow me to ask about the notes of heaven?'

Tzu-Ch'i replied, 'When the wind blows, the sounds from the myriad apertures are each different, and its cessation makes them stop of themselves. Both these things arise from themselves – what other agency could there be exciting them?'

This early passage shows us with poetic fullness the way in which all of nature was conceived of as emitting musical notes analogous to those of the pitch-pipes. It will help us to understand how the following strange procedure was instituted, and how such a thing could possibly occur to any sensible human being.

In order to verify the correct lengths of the standard pitch-pipes, and thus confirm the pitches emitted by them, which formed the basis for all measurement, by the first century BC the procedure known as 'observing the *ch'i'*, or 'the blowing of the ashes', was instituted. As Needham says: 'Some ancient

nature-philosophers set out to trap the *ch'i* ... which rose up from the earth combining with the *ch'i* which descended from heaven to produce the different types of wind that blew at different seasons of the year.'

There were, as we have seen previously, twelve basic pitches, and a set of twelve standard pitch-pipes to emit them. But since there were twelve months, the Chinese, who loved to correlate things, assigned one pitch-pipe to each month of the year. As the official history of the first century BC tells us: 'The *ch'i* of heaven and earth combine and produce wind. The windy *ch'i* of heaven and earth correct the twelve pitch fixations.' How did they do this?

An obscure author known as 'Humble Tsan', whose real name is thought to be Yu Tsan, He Tsan or Fu Tsan, writing at some date prior to the end of the fourth century AD, gives the traditional explanation: 'The *ch'i* associated with wind being correct, the *ch'i* for each of the twelve months causes a sympathetic reaction in the pitch-pipes; the pitch-pipes related serially to the months never go astray in their serial order.'

This makes clear that experimental standard pitch-pipes, twelve in number, were somehow 'activated' by subtle *ch'i* forces month by month, the appropriate pitch-pipe being 'activated' in its corresponding month. But what was the technique for accomplishing this, and how was the 'experiment' set up? 'Ts'ai Yung (c. 178 AD) gives the details:

The standard practice is to make a singleroomed building with three layers [concentric draught-proof walls]. The doors can be closed and barred off from the world outside, and the walls are carefully plastered so as to leave no cracks. In the inner chamber curtains of orange-coloured silk are spread out forming a tent over the pitch-pipes, and certain stands are made out of wood. Each pitch-pipe has its own particular stand, set slanting so that the inner side is low and the outer side high, all the pipes being arranged round the circle of compass-points in their proper corresponding positions. The upper ends of the pitch-pipes are stuffed with the ashes of reeds, and a watch kept upon them according to the calendar. When the emanation [ch'i] for a given month arrives, the ashes of the appropriate pitch-pipe fly out and the tube is cleared.

The official history for the first and second centuries AD adds:

They rely on calendrical calculation and so await the coming of the emanation [ch'i]; when it arrives the ashes are dispelled; that it is the emanation [ch'i] which does this is shown by the fact that its ashes are scattered. If blown by human breath or ordinary wind its ashes would remain together.

Thus do we see the full lunacy of the 'observing the ch'i'. This procedure was practised for at least 1700 years, from the first century BC or earlier, up to the sixteenth century AD, when it was finally discredited as ridiculous. As Needham says: 'We are tempted to feel that there must have been some genuine natural phenomenon, even if only once observed, which sufficed to keep this strange technique living for a dozen centuries. However that may be, no rational basis for the system can be suggested...

But as a by-product of the obsessive need to take precautions to safeguard the correct 'observation of the *ch'i'* and its effects on the pitch-pipes (which in the palace were all made of jade), we find that there arose what was genuinely the world's first attempt at a hermetically sealed research laboratory. Needham has summarized the matter thus:

The most interesting part of this strange experiment is the care which seems to have been taken to ensure that no ordinary wind could enter the sealed chamber. This sealing is perhaps really the most significant technical feature of the whole story. The precautions against chance breaths of wind and other disturbances reached their greatest degree of elaboration by the middle of the sixth century AD. Besides the tent of orange silk, gauze covers were fitted for each pitch-pipe individually. According to the descriptions, the stands or holders for the pipes were rather like our retort-stands. And the walls were so arranged that the doors of the inner and outer walls were at the south, while the door of the middle wall was at the north. Thus there were imbricated corridors exactly as in modern photographic dark-room practice. These remarkable details of the pursuit of an essentially unreal phenomenon may be found in the commentary of the Yüeh Ling written by Hsiung An-Sheng about 570 AD, and in the Yo Shu Chu T'u Fa (Commentary and Illustrations for the Book of Acoustics and Music), due to the eminent mathematician and astronomer Hsintu Fang, his older contemporary.

Never until modern times can such elaborate procedures have been adopted, foreshadowing as they did the modern hermetically sealed research laboratory, as in the pursuit of the fantastic illusion of the supposed 'blowing of the ashes' in ancient China — an imaginary phenomenon of imaginary forces. It all goes to show that in the pursuit of the most irrational aims, the most rational of means may be developed and adopted.

Before leaving this bizarre subject, it is perhaps worth while taking note of some attempts to explain it made by Chinese skeptics of the sixteenth century. These have been studied by Professor Derk Bodde, who in his essay on the subject speaks of 'watching

for the ethers' rather than 'observing the *ch'i*'. Sometimes fans were meant to revolve with the *ch'i* when the ashes were blown out of the successive pitch-pipes. Bodde quotes a scathing attack by Hsing Yün-lu in 1580:

I understand it! The movements of the fans and flying of the ashes were all based on mechanisms ... with men operating these mechanisms, the fans would move and the ashes would fly without fail, at the appointed times. These false things were secretly done in order to deceive the [emperor]. Unto the present day, officials of the Imperial Board of Astronomy ... using mechanisms, manufacture a false watching for the ethers with ashes.

Another skeptic pointed out that if the pitch-pipe in the north of the laboratory were meant to respond with an appropriate blowing of the ashes because it was north, one could move the laboratory a few yards further north until the exact same pitch-pipe location had become the south. Would a pitch-pipe in precisely the same patch of ground then not be activated? And if so, then clearly the *ch'i* was not rising from the Earth in the way claimed.

In the end, the curious saga of the hermetically sealed research laboratory helped to bring about a rise in rational thought in China by offering the opportunity for sharper minds to explode what was either a superstitious absurdity or a long-standing case of fraud by the emperor's scientists.

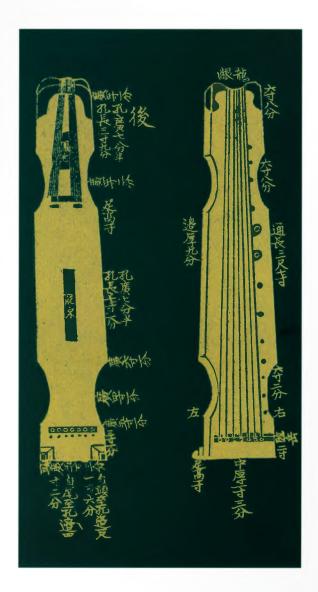

# THE FIRST UNDERSTANDING OF MUSICAL TIMBRE

THIRD CENTURY AD

We have already mentioned timbre. It is sometimes called the 'quality' of a musical note. It may be defined as the original fundamental note sounded, together with the overtones present with it. A tuning-fork has no timbre, because it merely sounds the fundamental note free of overtones; but the rich and resonant sounds produced by a modern piano are a triumph of the art of production of harmonious timbre. The only sources of harmonious timbre possible in non-electronic musical instruments are vibrating strings and vibrating columns of air (as in pipes or flutes). Bells can be acceptably harmonious in their

timbre, but percussion instruments have bad timbre.

The Chinese achieved a deep and profound understanding of timbre, and went further than any other culture, before or since, in exploiting it for musical purposes. The ancient Chinese zither known as the *ku ch'in*, or just simply *ch'in* (sometimes called the classical Chinese lute, though it is in reality a half-tube zither, usually of seven strings but originally of five and occasionally of nine) is, as Needham tells us, 'the only

ABOVE (158) A woodcut from the Korean encyclopedia, *Patterns in Musicology*, published in 1493, showing the seven-stringed Chinese zither called the *ku ch'in*, the world's only stringed instrument with no frets. The underside, showing the attachments of the silk strings, is on the left. The *ku ch'in*, or often just *ch'in*, relies for its music upon changes in timbre of its seven notes. These are both highly subtle and surprisingly varied.

ABOVE (159) A Chinese scholar sits reflectively at his table with his *ku ch'in*, which he is strumming with his left hand. Because the instrument has no frets, two hands are not absolutely necessary. His attendant seems riveted by the scene. Watercolour on paper, eighteenth century. (Nottingham Castle Art Gallery; Bridgeman Art Library.)

musical instrument in any culture which has no frets and actually marks the nodes of vibration on the board'. The very fact that there can be such a thing as a stringed instrument whose only musical purpose is the production of timbre variations is astonishing in itself.

The point of this instrument was that the strings were not played in such a way as ever to change their pitch, as happens when a string is pressed onto a fret in other instruments, such as the guitar or the violin. The *ch'in* was played with each string remaining at the same pitch at all times, and the art of playing was the production of different timbres of each string at constant pitch. This is so subtle that many Westerners might balk and question whether the result would strictly be music at all. But it is in fact a wonderfully rich and satisfying music.

The strings of the *ch'in* are all of silk. The traditional manner of playing them involved more than twenty-six different 'touches' or means of plucking or stroking them, for vibrato alone. R.H. van Gulik describes one vibrato technique in *The Lore of the Chinese Lute*, published in 1940, as follows:

Remarkable is the *ting yin*, where the vacillating movement of the finger should be so subtle as to be hardly noticeable. Some handbooks say that one should not move the finger at all, but let the timbre be influenced by the pulsation of the blood in the fingertip, pressing the string down on the board a little more fully and heavily than usual.

Needham comments on 'the infinite subtlety with which any given note could be played,' and remarks: 'Indeed, even today an expert *ch'in* player will himself remain intently listening long after a note has become inaudible to other listeners. As Taoist thought put it (in the Book of Lao Tzu): "The greatest music has the most tenuous notes."

The subtleties of the *ch'in* caused it to appeal to the Chinese literati, who ended by monopolizing it. At first it was the only musical instrument which a gentleman considered worthy of his playing. Then, so fashionable did it become that every educated man thought it best to have one hanging on his wall, whether he used it or not. And finally, only gentlemen were supposed to play the *ch'in*. This led to a decline in musical standards, since the educated classes naively believed that the

qualification for playing the instrument was not musical ability or skill but whether one knew classical literature and poetry and were 'refined'. One direct result was that ch'in music became less musical, and was less employed for accompanying singing. The emphasis shifted to the production of the different sorts of timbre for their own sake, rather than as part of musical compositions. Literati would sit and listen to series of subtle timbre variations almost without melodic line. So little did melody matter that the great compilation of ch'in music containing 468 tunes was actually lost, at the very time when the numbers of instruments was increasing dramatically. But whereas the musicality declined, the scientific understanding of timbre increased. The adoption of this instrument by the literati therefore both preserved the instrument into an era (the seventeenth century onwards) when it might otherwise have become extinct like the Great Lute, and at the same time advanced musical theory considerably.

The playing of the *ch'in* obviously required a musical notation different from usual. Musical notation for this instrument took the form of instructions, not only on which strings were to be used, note by note, but on the 'touch' by which the fingers were to play each note. Many pieces of music for this instrument also survive which additionally indicate that the rising or falling intonation of the words sung by the singer were to be accompanied by the zither; the change in voice intonation was matched by the variations in timbre of the instrument — a particularly subtle musical technique.

Chinese understanding of the nature of sound as vibration was much increased by studying the production of timbre on the strings of the ch'in. When a string vibrates, a wave is manifested in the string, and there are points called 'nodes' where the string remains stationary. Players of the ch'in would have become aware that touching a vibrating string at a node has no effect on the vibration, but touching it anywhere else causes the vibration to cease. And the many 'touches' used in playing the ch'in exploited these phenomena to the full, in the manipulation of timbre. Since timbre is the sum total of the fundamental note and its higher harmonics, which are of varying consonance and dissonance, the elimination of various of the overtones while leaving others could have a substantial effect.

octaves up.

We can reproduce the essentials of *ch'in* playing on common stringed instruments, and skilled violinists often do this. But if we turn to the piano, let us play the note middle C. If while the string vibrates, we then touch it precisely in the mid-point, we silence the fundamental tone (the note itself) as well as the overtones G of the next octave and E of the octave above that. But the two C notes at one and two octaves removed from the original will continue to sound from the touched string, as will the note G three

We can thus 'select out' various overtones and higher harmonics, while leaving others. This is a manipulation of the timbre of a single string such as was practised with elaborate and manifold skill by the *ch'in* players. And in the study and manipulation of timbre, the stretched string, with its utter precision, is the perfect medium. For its higher harmonics are described by simple numerical relations. These overtones theoretically continue to infinity; indeed, in that triumph of resonance, the modern piano, no less than forty-two overtones have been recorded and detected from the vibration of a single string.

The silken strings of the *ch'in* could not be subjected to sufficient tension to be capable of such enormous feats, but they did very well, for silk is extremely strong, and the strings were made of intertwined silken threads sometimes numbering seventy or eighty per string.

The understanding of timbre, overtones and higher harmonics meant that the Chinese were able to contemplate those phenomena of consonance and dissonance which eventually led them to invent the equally tempered musical scales (described in the next account), which most musicians believe to have been invented in the West. One incitement to invent the equal temperament of scales is to avoid certain sounds regarded as dissonant, and knowledge and appreciation of such dissonances partially comes from understanding timbre. For instance, in a vibrating string, the overtones represented mathematically by odd numbers occurring above the fifth are generally considered dissonant sounds to the fundamental note.

The observations of vibration of stretched strings in China were scientifically just about as advanced by the third century AD (when we know for certain that the techniques of the *ch'in* had reached a refined stage) as they were by the nineteenth century in Europe.

### EQUAL TEMPERAMENT IN MUSIC

SIXTEENTH CENTURY AD

The inventor of equal temperament in music was Chu Tsai-Yü, who published his invention in 1584. The first mention of Chu Tsai-Yü's invention was in the unpublished papers of the great mathematician Simon Stevin (died 1620). Chu Tsai-Yü was born in 1536, a prince of the Ming Dynasty. But he turned his back on his princely rank and concentrated instead on studying music, mathematics and the science of the calendar. His system of equal temperament appeared in his book *A New Account of the Science of the Pitch-Pipes*, published in 1584. The Chinese did not pay much attention to the new system, but the Europeans quickly saw its advantages.

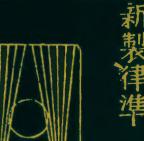

Two years earlier, the great Chinese scholar of the Jesuits, Matte Ricci, commenced his studies at Macao. From 1580, the Viceroy of the Cantonese province had established biannual 'radio fairs' lasting several weeks, at which Chinese and Westerners exchanged ideas and goods. The interchange between East and West was intense just at the moment when Chu Tsai-Yü went into print with his new theory. It is a case of perfect timing which gives one the feeling that it was 'fated' to happen. We do not know the exact mode of transmission of the idea to Europe; there can be no doubt that Western music was to be totally conquered by the Ming prince, for within 52 years of Chum's publication, his ideas were published by Père Marin Mersenne. The Ming Dynasty ended eight years later, but Ming music today blares from every transistor radio in the world.

The first published reference to the mathematical basis for equal temperament in Europe was by Mersenne in one of his many books of musical theory, entitled *Harmonie Universelle*, issued in 1636. Werkmeister later popularized equal temperament, and Johann Sebastian Bach took up the cudgels on its behalf by composing a series of pieces, collectively entitled *Das Wohl-temperierte Klavier (The Well-Tempered Clavier)*, consisting of 'preludes and fugues in all the tones and semitones ... for the use and practice of young musicians who desire to learn, as well as by way of amusement, for those who are already skilled in this study'.

This epochal work was published in 1722. Yet probably only a few of all those who have ever listened to or played these pieces have had any idea of

ABOVE (160) A painting of a girl playing to an emperor on the lute. His intent stare is not meant to be intimidating: it is evidence of the extreme seriousness with which music was often viewed at court. Such attitudes were partially responsible for the Ming Prince Chu Tsai-Yü's many years spent on the study of musical theory, resulting in his original idea of equal temperament. (British Museum, London.)

正面小樣

Bach's underlying intentions. The Well-Tempered Clavier was a work of propaganda. Bach had adopted equal temperament with a passion later to be matched by that of his fellow-composer Giuseppe Tartini's opposition to it. Equal temperament allows one to modulate fluently from key to key consecutively in the composition and performance of music. It was passionately adopted by those who thought the practical advantages of this were paramount, and was as passionately opposed by those who thought that purity of tone and other substantial factors should not be sacrificed to such base utility. These frenzied debates and disagreements have died down now in the West, at least for the moment. Equal temperament, so hugely aided by the prestige of Bach, triumphed utterly during the nineteenth century, yet many of today's musical experts do not really understand its principles, and no more than a handful of Westerners can now appreciate what music would sound like without it.

The only way for the reader to appreciate the magnitude of this subject is for us to consider the underlying problem which makes perfection of tone in all musical composition impossible. It is one of the most fascinating but least known of the fundamental enigmas of the Universe. There is no music conceivable, on whatever planet, in whatever galaxy, where the dilemma could be escaped.

Let us illustrate the matter in a simple way by discussing a piano. Most people know that a note struck simultaneously with a note eight notes higher (in a scale) is an 'octave'. The low note and the high note are the same (say a C), except that the high note is 'C an octave higher than the lower C'. The higher one is double the frequency of the lower one. This is true whatever note is played; an 'octave' is defined as a note of a particular frequency sounded with a note of twice that frequency. Octaves are quite simple. They are also rather boring, because the same notes sounded an octave apart have no variety. There is neither consonance nor dissonance; there is just

OPPOSITE (161) Prince Chu Tsai-Yü invented equal temperament in music, and published the idea in 1584 in his *New Account of the Science of the Pitch-Pipes*. This woodcut of his personal tuning instrument is from the book, in which he proudly stated: 'I have founded a new system.' Little could he have realized that his system would be universally adopted in the West. Johann Sebastian Bach was its leading promoter.

uniformity. An octave is like a man standing and staring at a photograph of himself which he holds in his hand: a simple double image. How much more interesting it would be if the man were to stand with his arm around a woman whom he loves, or were to be scowling at one whom he hates. The first would be a consonance, and the second would be a dissonance. The interest of life is in variety and juxtaposition; hence, a C played with any other note than another C takes on greater interest to us than the octave.

The most pleasing consonance of two notes sounded together is what is called a 'fifth'. This is not simply subjective; an analysis of the sound waves involved shows that the higher harmonics of the notes have consonant beats with one another. But there does remain a mystery about the preference human beings find for harmony and the annoyance they experience upon hearing dissonance. Sir James Jeans has written: 'It must be admitted, however, that [there] is a defect of most theories of discord. Innumerable theories are ready to tell us the origin of the annoyance we feel on hearing a discord, but none even attempts to tell us the origin of the pleasure we feel on hearing harmony; indeed, ridiculous though it may seem, this latter remains one of the unsolved problems of music.'

What, then, is this most pleasing and harmonic of all joint sounds, the fifth? For it was the fifth rather than the octave which was the basis for Chinese music. A typical example would be the chord CG. If you then play successive fifths, using the top note of one fifth as the bottom note of a new fifth, you do not come to a C again for quite some time (CGDAEBF#C#AbEbBbFC). In fact, you have a succession of twelve fifths before reaching another.

Musical theorists like to speak of the ascending fifths as a 'spiral of fifths', and they draw them in a diagram spiraling upwards. If you count the number of octaves between the first and last note in a spiral of twelve fifths, you will find that there are seven. As the spiral has gone round, it has repeatedly missed the higher octave notes of the original note, until finally after twelve fifths it hits the seventh octave of the original note. Then and only then do the two separate ascending series meet.

An upward (or downward) spiral of fifths and an upward (or downward) spiral of octaves thus only meet up when twelve fifths and seven octaves end on the same note. Until then, on their upward or downward courses, the two means of proceeding

have been quite separate. It is as if two runners were running the same distance on two separate tracks which went over and under one another repeatedly until they reached the same finishing post, at a point where the separate tracks met for the first time since the start.

This is important, for upon examining this more closely we find that it is not as simple as it seems there is something curiously wrong. The problem is this: musical tones are very precisely measurable in the laboratory, and an exact number is assigned to every note as its frequency. Now, when one plays a C seven octaves higher than another C, we find that its frequency is 128 times that of the original. (Every octave doubles the frequency, and if you progressively double something seven times you have in fact made it 128 times its original self.) But if you want to have a sequence of fifths which increase by 1.5 times the original frequency (which is what fifths do) twelve times over, you will achieve a final result not exactly equal to the 128 of seven octaves, but equal instead to the slightly different amount of 129.75, which is the value of  $(1.5)^{12}$ .

The fact is that the mathematics of the fifth is incommensurable with the mathematics of the octave. A note which is a *fifth* higher than another note has a measurable frequency one-and-a-half times that of the lower note. And the number 1.5 is arithmetically incommensurable with the number 2 (which expresses the doubling of the frequency of a note when raised an octave). So the fifth and the octave are out of joint with each other on fundamental arithmetical

grounds. The spiral of fifths comes to

a stop at a point which is 1.0136 times the sequence of octaves.

(Or, the frequency 129.75 is 1.0136th that of 128). This value, 1.0136, is known as 'the comma of Pythagoras', after the Greek philosopher who discussed it.

The different keys are established in Chinese music by the twelve different notes of e spiral of fifths, and these twelve notes are all

the spiral of fifths, and these twelve notes are all found within the compass of a single fundamental octave. The spiral of fifths ascends from C to G to D to A to E to B to F# to C# to Ab to Eb to Bb to F back to C (except, as just mentioned, this C is not absolutely precise). It will be appreciated that all of these notes fall between one C and the higher or lower C, and give the twelve keys. These twelve

notes also give the complete chromatic scale of modern music.

Equal temperament is an artificial system created to get round the fact that the spiral of fifths ends on a note slightly off the end of the sequence of octaves. The tiny fraction of 0.0136 is divided into twelve equal parts, and each part is subtracted from one of the twelve notes into which an octave is divided. This means that the gap between a note and its 'fifth' is no longer precisely 1.5, but is instead a tiny fraction less, namely 1.4983. This 'violence' done to all the fifths squeezes them into the tinier space of a pure octave. All twelve steps in the octave are now precisely equal, and are called semitones. In order to accomplish this, each fifth has been artificially but evenly rendered flat by about one forty-eighth of a semitone. All equally tempered music is thus uniformly and unremittingly 'flat'. But it provides a regular and reliable structure so that one can modulate from key to key, for as much richness and variety of composition as one could desire.

This is not to say that much has not been lost – sacrificed on the altar of utility. Our modern ears have been so debased by hearing only equally tempered music that we no longer know a pure tone. We send for a piano tuner to tune our piano, but in fact he comes and tunes it flat, note by note, as relentlessly as ants march forth from their nest. We are thus subjected, from birth to death, to nothing but flat notes. We never so much as hear a pure tone.

Before equal temperament, in both China and the West, there were various 'modes' of untempered music. For the sake of simplicity, we can speak as well of the ancient Greek ones, which have less difficult names, though they all have Chinese equivalents. There were the Ionian, Dorian, Phrygian, Lydian, Mixo-Lydian, Aeolian and Locrian modes. Instruments could be tuned to only one mode at a time. Some of the modes were happy and carefree, while others were sad and mournful. They represented a vast richness of emotional intensity and experience which has now completely and utterly vanished from the music known to us today. It is impossible to describe them: the colourations and subtleties of the differing modes were somewhat like the difference which we know between major and minor keys, multiplied several times. In the absence of these old modes, not a single person in the entire Western world unafflicted by deafness can avoid hearing at every turn music fashioned from an imported Chinese theory.

# CHEMICAL WARFARE, POISON GAS, SMOKE BOMBS AND TEAR GAS

FOURTH CENTURY BC

Chemical warfare using poison gas goes back to at least the early fourth century BC in China. It is described in writings of that date by the sect known as the Mohists, founded by a philosopher and social reformer called Mo Ti. In the early Mohist writings, we read of the use of bellows to pump poison gas down into the tunnels of enemies besieging cities. The bellows were made of ox hide and connected to furnaces in which balls of dried mustard and other toxic vegetable matter were burnt – anticipating the mustard gas of the trenches in the First World War by 2300 years.

The use of poison gas was a natural development from the traditional Chinese custom of fumigation of houses, known to be practised in the seventh century BC. Fumigation was also widely practised to kill bookworms; this function was exploited after the introduction of paper (page 92). Even the virtues of steam were appreciated as early as the tenth century AD, when the Chinese seem to have realized that steam could sterilize. Lu Tsan-Ning wrote in his book *Simple Discourses on the Investigation of Things* in 980:

When there is an epidemic of a feverish disease, let the clothes of the sick person be collected as soon as possible after the onset of the malady and thoroughly steamed; in this way the rest of the family will escape infection.

The earliest use of poisons in warfare was obviously the poison-tipped arrow, which was already widespread in many corners of the world, its origins rooted in indefinite antiquity. The next step was the systematic Chinese use of poison gas. The Chinese appreciation of the properties of many gases was perhaps aided by the fact that, unlike Westerners, Chinese did not draw hard and fast distinctions between spirit and matter. For the Chinese, all matter faded into ever subtler gradations of tenuous, ethereal matter. They even believed in a genuine physical immortality of tenuous, ethereal human bodies: if a sage lost weight and appeared to be wasting away before one's eyes (often as the result of poisons in his elixirs), this was looked upon as a marvellous process. He was 'lightening' and was on his way towards physical immortality in the form of a spirit - that spirit being considered entirely material, but at the same time, merely tenuous. Belief in this sort of thing obviously led the Chinese to take great interest in tenuous matter of whatever kind, and drew their attention towards gases. The property of evaporation was even seen as an analogy to what humans could look forward to if they were fortunate and took the right potions.

Elsewhere, in the account of the origin of gunpowder (page 250), mention is made of the tradition of incorporating the poison arsenic in many gunpowder mixtures. This may have arisen from an association of arsenic preparation with the first inadvertent discovery of gunpowder. But it was not simply habit and tradition

OPPOSITE (163) The Chinese were using poison gas, including the smoke of burning dried mustard, by the fourth century BC in warfare. Here mustard gas is being used by the Germans against the Allies during the First World War, 2300 years later.

which were involved. Bizarre and terrible poisons were mixed together in a very large proportion of the bombs and grenades of the Chinese (for which, see page 256). One of the most disgusting must certainly have been the medieval excrement bomb, for which we have the recipe:

Ingredients:	Weight in Ounces
Human excrement,	
dried, powdered	
and sifted very fine	240 (15 lb)
Wolfsbane	8
Aconite	8
Croton oil	8
Soap-bean pods	
(to create black smoke)	8
Arsenious oxide	8
Arsenic sulphide	8
Cantharides beetles	
(Mylabris cinchorii)	4
Ashes	16
Tung oil (from either	
Aleurites fordii or	
Perilla nankingensis)	8
Total for one bomb:	316 oz (19.75 lb

This would have created a stink bomb spreading excrement dust combined with some pretty deadly poisons all over the enemy. All of the above ingredients were either surrounded by or combined with a gunpowder mixture, wrapped in layers of paper which were tied with hemp string and covered with melted resin. This deadly packet would be hurled by a piece of artillery called a trebuchet, which held the bomb on a sling which would be whipped up in the air on an arm. A lighted fuse would cause the bomb to ignite either over the heads of the enemy, or shortly after landing, when it would have burnt fiercely and spread its foul smoke in thick clouds.

Directions also survive as to how to mix poison bomb recipes. For instance, sulphur and saltpetre were pounded together and passed through a sieve. Arsenic and white lead would be ground together. Dried lacquer would be pounded separately into a powder (it was a powerful chemical irritant). Yellow wax, pine resin and various oils would be boiled together into a paste, and the powdered chemicals added to turn it into a thick soupy mass, constantly and carefully stirred. Smaller poison bombs with lighted fuses could be fired from bows or crossbows. In the fourth century BC the Mohists had burnt poisons in a furnace, drawn the deadly smoke off in pipes and blown it with bellows down tunnels constructed by the enemy. But by medieval times, poison bombs were let down and exploded in the tunnels instead. Bamboo fans were used to drive smoke and flame down the tunnels, to stifle and burn the enemy.

The equivalent of our modern tear gas was a blinding smoke, created by bellows blowing out finely powdered lime, which made the eyes run profusely. Yang Wan-Li in his book *Rhapsodic Ode on the Sea-eel Paddle-Wheel Warships* describes a sea fight of 1161 where tear gas was used effectively:

In the Shao-Hsing reign-period, the rebels of Wanyen Liang came to the north bank of the River in force ... but our fleet was hidden.... Then all of a sudden a thunderclap bomb was let off. It was made with paper carton and filled with lime and sulphur. Launched from trebuchets these thunderclap bombs came dropping down from the air, and upon meeting the water exploded with a noise like thunder, the sulphur bursting into flames. The carton case rebounded and broke, scattering the lime to form a smoky fog which blinded the eyes of men and horses so that they could see nothing. Our ships then went forward to attack theirs, and their men and horses were all drowned, so that they were utterly defeated.

We have better descriptions of these tear gas bombs in an account of the campaign of the Sung general Yo Fei against the bandit chief Yang Yao in 1135:

...the army also made 'lime-bombs'. Very thin and brittle earthenware containers were filled with poisonous chemicals, powdered lime, and iron calthrops [sharp pointed objects to injure feet]. In combat they were used to assail the enemy's ships. The lime formed clouds of fog in the air, so that the rebel soldiers could not open their eyes. They wished to make the same kinds of things themselves, but their potters were not able to produce them, so they suffered great defeats.

Chinese tear gas was in fact in use by the second century AD at the latest. The dynastic history relates this suppression of a peasant revolt in the year 178:

The bandits were numerous, and Yang's forces very weak, so his men were filled with alarm and despondency. But he organized several horse-drawn vehicles carrying bellows to blow powdered lime strongly forth, he caused incendiary rags to be tied to the tails of a number of horses, and he prepared other vehicles full of bowmen and crossbowmen. The lime chariots went forward first, and as the bellows were plied the smoke was blown forwards according to the wind, then the rags were kindled and the frightened horses rushed forwards throwing the enemy lines into confusion, after which the bowmen and crossbowmen opened fire, and drums and gongs were sounded, and the terrified enemy was utterly destroyed and dispersed. Many were killed and wounded, and their commander beheaded.

Sometimes the recipes for poison bombs are positively gleeful at the hideous effects caused. One fourteenth-century bomb described in *The Fire-Drake Artillery Manual* of 1412 is the 'bee swarm bomb', producing a burning fire which 'comes forth (and) can stick to the enemy's person and still burn.'The book adds dolefully that (unfortunately) 'it can be extinguished with water.' And from the same book we hear also of the 'flying-sand magic bomb releasing ten thousand fires'. It consisted of a tube of gunpowder put into an earthenware pot containing quicklime, resin, and alcoholic extracts of poisonous plants. It was thrown down from city walls, and its explosion released the deadly poisons.

Poisons, poisonous gases, and tear gas were not only delivered by bombs and grenades. They were fired from guns and proto-guns, as described elsewhere (page 266). An early proto-cannon in the fourteenth century was called the 'poison-fog magic-smoke eruptor', and *The Fire-Drake Artillery Manual* recounts its amazing properties:

RIGHT (164) A medieval artillery piece, known as 'the heavenrumbling thunderclap fierce fire eruptor', which fired poison smoke shells at the enemy. If blinding gunpowder, flying gunpowder, poison gunpowder, and spurting gunpowder are filled into a shell and fired at the top of a city wall, fire will break out and smoke will spread in all directions as the shell explodes. Enemy soldiers will get their faces and eyes burnt, and the smoke will attack their noses, mouths and eyes. If the right moment is chosen, no defenders can withstand such an attack.

Among the many sorts of gunpowder whose formulae are given by the early Chinese, several are specified as tear gas mixtures or poison gas producers. A classic tear gas mixture was called 'five-league fog'. It contained a mere 27.8 per cent saltpetre, the same amount of sulphur, and 44.3 per cent carbon. It must have burned slowly, and contained arsenic, sawdust, resin, human hair and chicken, wolf and human excrement. A poison gas bomb called 'soul-hunting fog' contained a very strong explosive with 83 per cent saltpetre, a mere 8.3 per cent sulphur, and 8.4 per cent carbon, together with arsenic sulphides and deadly animal poisons. These bombs are at the two extremes of slow burning and strongly explosive. Practically every animal, plant and mineral poison imaginable was combined in one or another mixture

by the Chinese. There hardly seemed to be a deadly substance unknown to them.

They were also informed as to the various effects of the different poisons. A text of 1606 tells us that certain ones will 'cause the enemy's flesh to rot until the bone shows', whereas with dolphin oil, Szechuan varnish and arum poison the enemy will be struck dumb. It adds: 'Smoke from burning wolf excrement, which looks red both in the daytime and on dark nights, can be used for sending warning signals.'

The development of rockets for warfare (see page 262) added a new method of delivering poisonous bombs. The 'free-flying enemy-pounding thunder-crash bomb' used this method. When its rocket charge had exhausted itself the fuse was lit and the bomb fell, releasing a poisonous and irritating smoke even though the bomb was only 5½ inches in diameter.

When did these deadly practices reach Europe? In 1540, Vanoccio Biringuccio in his book *Pirotechnia* described typical Chinese formulae for use in firelances. They contained arsenic and the usual poisons. He remarked that when lighted, they sent out 'a very hot tongue of flame more than 2 or 3 yards long, full of explosions and horror'. Even earlier, Leonardo da Vinci had envisaged attacking the enemy with sulphurous smokes, fumes of burnt feathers, sulphur and arsenic, and even toad and tarantula venoms mixed with rabid saliva and conveyed by bombs. That was about 1500. And until 1580 arsenic was a great favourite in Europe. But it was replaced by mercury smoke balls in the seventeenth century. Such, then, is one of China's more baleful gifts to the world.

#### THE CROSSBOW

FOURTH CENTURY BC

For more than two millennia the crossbow was the standard weapon of Chinese armies. In fact, it was used by the Chinese as recently as 1895, by which time, of course, it was largely ineffective against modern European guns. The crossbow was invented in China in its form as an actual weapon, but the original idea for it came from the primitive bow-trap used by aboriginal peoples to kill game. When a person holds an ordinary bow, he holds it vertically. In setting a bow-trap, however, the bow must be laid horizontal. Furthermore, a stick or long piece of wood must be placed against the bow, at the far end of which the bowstring is pulled taut. Then when an

animal comes along and knocks the trip-wire with its foot, the stick is pulled away and the bow fires its arrow at the animal, which is collected by the hunter later as he makes his rounds. Thus, the form of the crossbow was implicit in these primitive beginnings from earliest times.

It later appeared in Europe at two widely separated times; each transmission of the invention is thought to have been from China. Even in neighboring India, though the bow-trap was commonly used in Bengal against tigers, the actual crossbow was only introduced for the first time by the Mogul conquerors of the Middle Ages.

A Chinese text compiled from earlier materials in the second century AD credits the invention of the crossbow to a Mr Ch'in of Ch'u, who was an archery student of Feng Meng. If Feng Meng really existed and was not just a mythical personage, then this date would be the seventh century BC. Unfortunately, we have too few texts from these early periods to be certain of such things. During the Han Dynasty, around the time of Christ, an archery manual by Feng Meng existed — though it has since been lost. This may or may not have been the real name of the author, and he may or may not have been the teacher of Mr Ch'in. This is what we are told about Mr Ch'in himself:

Mr Ch'in considered, however, that the bow and arrow was no longer sufficient to keep the world in obedience, for in his time all the feudal lords were fighting against one another with weapons, and could not be controlled by ordinary archery. He therefore added at rightangles to the bow a stock and established a trigger-mechanism within a box or housing, thus increasing its strength. In this way all the feudal lords could be subdued. Mr Ch'in transmitted his invention to the Three Lords of Ch'u ... and it was from them that Ling Wang [reigned 539-527 BC] got it. As he himself said, before their time the men of Ch'u had for several generations guarded their frontiers only with bows of peachwood and arrows of thorn.

There is additional evidence to indicate that the crossbow was indeed invented in the kingdom of Ch'u, and it would appear that Mr Ch'in may have been a real person who did indeed live in Ch'u in the century before Confucius. However, Needham suggests that what Mr Ch'in may really have invented

RIGHT (165) A repeating or 'machine-gun' crossbow, capable of firing eleven bolts in fifteen seconds. The magazine resting on top can carry ten bolts. Three of the bolts are displayed beside the weapon. Such repeating crossbows were invented about the eleventh century and were common by the year 1600 in China. They had an effective range of about 80 yards with an extreme range of 200 yards. They provided the earliest form of 'reconnaissance by fire', such as was practised in the Vietnam War (by shooting a spray of bullets). Large numbers of these fired at once could deter most 'human wave' attacks of soldiers. The length of this weapon is 39 inches, with the bolts 14½ inches long. (Simon Archery Foundation, Manchester Museum, University of Manchester.)

was a trigger-mechanism. An earlier form of the crossbow may already have existed. The earliest textual evidence of the crossbow is from a book called *Master Sun's Art of War*, which dates from at least 345 BC and is reputed to date from 498 BC. This book says that 'energy may be likened to the bending of a crossbow, decision to the releasing of the trigger'. The use of such an image can have had little point unless crossbows were sufficiently familiar to the reader for the statement to make sense.

By the fourth century BC the use of crossbows in battle is recorded by Sun Pin, a descendant of Master Sun, who wrote that: 'A very strong body of crossbowmen' was decisive in a victory obtained in that century at the Battle of Ma Ling. Elsewhere, in 336 BC, the official Su Ch'in was recorded as boasting that the Prince of Han has '10,000 suits of armour and the strongest bows and crossbows in the world'.

Dr E.M. Grosser has published a very detailed account of what may be the earliest surviving crossbow. It is a pistol-crossbow, to be held in the hand like a modern handgun. The design on top has been attributed, on stylistic grounds, to the early Chou Dynasty, which might place this excavated bronze pistol-crossbow in the eighth or ninth century BC, or even earlier. However, the earliest certain archeological evidence for crossbows are depictions of them on inlaid bronze vessels, which apparently date from the beginning of the fourth century BC. Further textual evidence from that century exists in the Mohist texts

on fortification engineering in *The Book of Master Mo*, which speaks not only of ordinary crossbows but also of large multiple-bolt *arcuballistae* (crossbow-cannons) used for sieges.

By the third century BC textual references to crossbows become abundant. Master Lu's Spring and Autumn Annals of 239 BC says: If the mechanism of a crossbow-trigger is out of alignment by no more than the size of a rice-grain, it will not work.' This is perfectly true. Indeed, the perfection of the bronze trigger-mechanisms is the most impressive of the Chinese achievements in developing the crossbow. The trigger-box was inset into the stock like a tenon into mortise, and had a groove on its upper surface for the arrow or bolt. The trigger (called 'hanging knife' by the ancient Chinese, since that is what it resembled) hangs down below the housing case rather like that of a modern gun. Despite the lack of metal lathes, the earliest surviving trigger-mechanisms manufactured to an incredible degree of machined accuracy, and even more impressive than their quality is the standardization that must have been required for their mass-production. A crossbow trigger-mechanism is a complicated device which contains within its housing three moving pieces on two shafts, each finely cast in bronze and machined to a precision which is difficult to imagine.

In order to appreciate the feat of protoindustrialization which this represented, we must know something of the quantities of crossbows RIGHT (166) A traditional Chinese crossbow, thought to be of the nineteenth century. The stock is 33½ inches long, constructed of wood, horn and sinew, with an inlay of rosettes and small discs of ivory, and painted paper underneath. The string is of gut. A sight is mounted on the front. (Simon Archery Foundation, Manchester Museum, University of Manchester.)

which had to be produced. In 209 BC, the Emperor Erh Shih had crossbow regiments numbering 50,000 men and a similar number of crossbowmen also served under the emperor Wen Ti in 177 BC. But lest we think that this meant that only a few tens of thousands of crossbows existed at this time, we are informed by China's great historian, Ssuma Ch'ien, that in about 157 BC, the prince Liang Hsiao Wang was in charge of arsenals containing several hundred thousand crossbows. This means that twenty-one centuries ago, the Chinese were capable of mass-producing complicated mechanisms which were first cast, then machined to a fine standard, and then assembled, in numbers of approximately half a million.

Surely this massive arms production in ancient times is an industrial achievement of the first order. The scholar Homer Dubs observed that the Chinese crossbow trigger-mechanism 'was almost as complicated as that of a modern rifle bolt, and could only be reproduced by very competent mechanics'. So complex were the mechanisms that the Huns were unable to assemble them or copy them. Crossbow arrows were also useless because they were too short for use with a long bow. Therefore, both the weapon and its ammunition were 'capture-proof', in the sense that even if captured they were guaranteed to be useless to the enemy.

The Chinese well appreciated their own advantage in armaments. Here is what Tseng Kung-Liang said in his book *Collection of the Most Important Military Techniques* published in 1044:

The crossbow is the strongest weapon of China and what the four kinds of barbarians most fear and obey.... The crossbow is the most efficient weapon of any, even at distances as small as 5 feet. The crossbowmen are mustered in separate companies, and when they shoot, nothing can stand in front of them, no enemy formation can keep its order. If attacked by cavalry, the crossbowmen will be as solid as a mountain, shooting off such volleys that nothing can remain alive before them. Although the charge may be impetuous it will not reach them. Therefore the barbarians fear the crossbow. Truly for struggling around strategic points among mountains and rivers and defiles, overcoming men who do not lack bravery, the crossbow is indispensable.

Regarding the method of using the crossbow, it cannot be mixed up with hand-to-hand weapons, and it is most beneficial when shot from high ground facing downwards. It only needs to be used so that the men within the formation are loading while the men in the front line of the formation are shooting. As they come forward they use shields to protect their flanks. Thus each in their turn they draw their crossbows and come up; then as soon as they have shot their bolts they return again into the formation. Thus the sound of the crossbows is incessant and the enemy can hardly even flee. Therefore we have the following drill:

shooting rank advancing rank loading rank. Such praise of the crossbow was traditional in China. Twelve centuries earlier, a eulogy of the weapon was recorded in the imperial official history for 169 BC, part of which says:

...the drill of crossbowmen alternately advancing to shoot and retiring to load; this is something which the Huns cannot even face. The troops with crossbows ride forward and shoot off their bolts in one direction; this is something which the leather armour and wooden shields of the Huns cannot resist. Then the horse-archers dismount and fight forward on foot with sword and bill; this is something which the Huns do not know how to do. Such are the merits of the Chinese.

Manufacture of crossbows was by division of labour. Most crossbow trigger-mechanisms which have been found have been inscribed by their makers, often giving dates. One was excavated in the eleventh century and examined by the writer Shen Kua. He wrote, mournfully, 'We never could find out what dynasty this crossbow mechanism belonged to', but it bore the inscription 'Stock by Yü Shih, rear work of the crossbar by mechanic Chang Jou'.

By the second century BC there was an imperial ban on the exportation of crossbows out of China, and in 125 BC barriers were set up at the frontiers to ensure that this could not happen. But these measures were too late, for crossbows had already been taken out of China. In the first century BC we know that they were to be found in Korea and as far west as Sogdiana in Central Asia. Within China, crossbow manufacture was a state monopoly and it was carried out with all the security precautions familiar to us with modern weapons manufacture today. Candidates for the civil service, in about the year 1030, had to answer a question in their examination, 'What would you do to detect and punish people who kept privately armour and crossbows in their homes?' Presumably only those who gave sufficiently harsh replies were allowed to join the imperial civil service.

Although crossbows came in all sizes, from pistol ones to huge artillery pieces, the problem was always one of arming them. It took a great deal of strength, so that the earlier crossbownnen had to be very strong in order to arm the weapons by brute strength alone, which involved standing on the bows and pulling the strings back with mighty heaves and grunts. Better

arming techniques were developed as time went on. Since China was the land where the stirrup was invented (see page 101), it is not so surprising that crossbows were eventually produced with stirrups attached to them, so that one could put one's foot in a stirrup to hold the bow down when rearming. (Standing on a bow was not possible in marshy ground, for instance.) Crossbow stirrups were standard issue to troops by at least the eleventh century. A later improvement was a double-pronged claw for the crossbowman's belt so that he could stand and draw the string of his weapon by the muscular power of leg and back alone, leaving his hands free to hold it, and manipulate the trigger-catch. This was called 'waistarming'. This technique was thought to have been used in the third century, and then lost for several centuries until revived in the Middle Ages. Rotary arming methods were also used. All of the great crossbowcannons were armed by winches which pulled back the strings, since no human being alone could possibly have done it. These seem to have been used as early as the eighth century, though relatively rarely, and in connection with sieges. (Regarding winches, it is worth remembering that it was the Chinese who invented the crank handle: see page 49.)

Grid-sights for aiming crossbows were invented in China by the first century AD. These grid-sights were the first in the world, and were similar to the ones used on modern photographic cameras and anti-aircraft guns. Mounted on both rear and forward ends of the stocks, the sights consisted of vertical and horizontal fine wires crossing each other in grids. A third-century text speaks of 'the forester, with his finger on the trigger, and his bow drawn, [who] aims at the target embraced in the graduations of his sights and lets fly'. An even earlier ranging device on the crossbow was a series of graduated notches on the lug of the trigger-mechanism, which goes back to at least the third century BC.

How powerful actually were these Chinese crossbows? A version developed by Li Ting in the eleventh century was made of mulberry wood with the body of brass and the string of hemp. It was presented to the emperor in the year 1068. This remarkable weapon 'could pierce a large elm from a distance of 140 paces.' This was very quickly made standard issue. A crossbow catapult, which took several persons to draw its string and consisted of two bows tied together, could shoot several arrows simultaneously, killing ten persons at a time. The extreme range of a large winch-armed Chinese crossbow was, according to

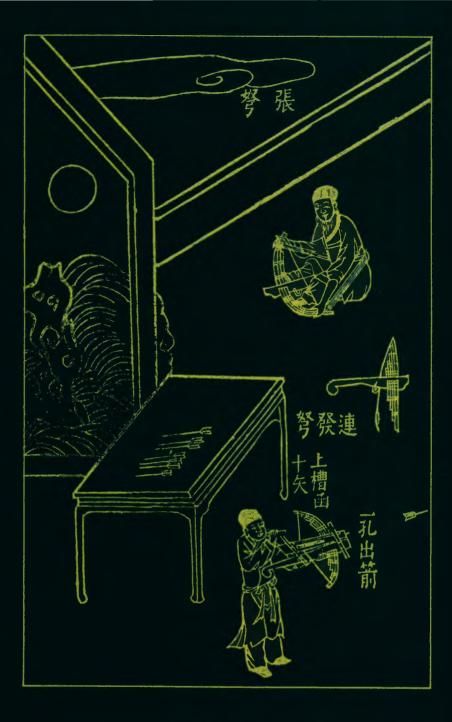

RIGHT (167) Mass manufactur of crossbows during the Ming Dynasty: the original production line, centuries before Henry Ford, and the real beginning of 'the military industrial complex' As early as 209 nc, 50,000 crossbows were used in a single battle on one side alone. Teams of a hundred archers could each fire 2000 rounds in 15 seconds. This engraving showing crossbows under construction was published in 1637 in The Greations of Nature and Man Theoretical Country in the Creations of Nature and Man

Needham, 1160 yards. This is only 600 yards short of a mile! It is all the more incredible that the date of this weapon was the eighth century. And at that time, the extreme range of a hand-held crossbow was 500 yards, and that of one fired from horseback was 330 yards.

Although crossbows were very accurate when fired at their extreme ranges from the ground, the necessity of raising the weapon in the air meant that one could not use the sights, and sacrificed accuracy of aim. The Chinese always preferred to use their crossbows from above, firing down

upon the enemy. For genuine accuracy at ground level, the range would be only about half the extreme range.

Some crossbows had tubes through which either arrows or bullets were fired. These tubes derived from the bow-tube used by longbowmen for sniping, with the arrow fired through a tube held as an arrow-guide (but this is dangerous, many an experienced bowman having fired an arrow right through his bow thumb by mistake). The word 'musket' is derived from the use of

old Italian crossbows with barrels which fired little bullets called *muschettae* ('gadflies'). The word passed from crossbows to barrel guns.

One of the reasons for the lethal effects of the crossbow was that poisoned arrows were commonly used. The poisons used were some of the most deadly in nature, and that meant that if a crossbow bolt scraped past a man's arm, or if he even pricked his finger by picking one up on the battlefield, he quickly

died. But since a properly aimed crossbow bolt could pierce through two suits of metal armour with ease, no one was safe.

The desire to enhance the fire-power of the crossbow led to the invention of machine-gun crossbows in about the eleventh or twelfth century. This development overcame the difficulty of arming the crossbow, which proceeded too slowly for rapid refiring. A magazine of bolts was fitted above the arrow-groove in the stock of the crossbow, and as each bolt was fired, another would drop into its place. The mechanism for firing a repeating crossbow was different from usual. The trigger was absent, and a lever was fixed permanently to the stock between the bowstave and the furthest rear position reached by the string when drawn. Pivoted to this lever was the magazine, which usually contained ten or twelve arrows. The lowest arrow rested upon the arrowgroove and against the string. There was a short barrel at the front. Upon pushing the lever forward as far as possible, the string fell into a slot at the rear end of the longitudinal slit along the base of the magazine, remaining caught in it while the lever was drawn backwards to its fullest extent, thus arming the weapon. At this stage the arrow would have dropped fully into the arrow-groove for firing. An 'automatic trigger', in the form of a short vertical hardwood pin moving up and down in the base of the magazine below the string slot, would be forced upwards by contact with the stock, and would release the string and hence the arrow.

This could be repeated so quickly that a dozen arrows could be fired within moments. Replicas have been constructed and tested, and it has been found that using these repeating crossbows, the Chinese could have one hundred men discharge 2000 arrows in 15 seconds. The ranges of repeating crossbows were less, the extreme being 200 yards, but with an effective range of 80 yards. Although the power of the weapon was diluted, such vast, rapid and continuous showers of bolts raining down on an enemy were said to be extremely demoralizing, especially when one considers that the bolts were usually poison-tipped. Machinegun crossbows were widespread in China by the year 1600 and many examples survive in museums. One may be seen in Plate 165 (page 245).

In Europe, crossbow-type artillery pieces were known to the ancient Greeks, who used them to fire bolts in sieges, and they were used in 397 BC at Syracuse. A Pythagorean named Zopyros of Tarentum

in Sicily developed some of these devices at approximately that time, two years after the death of Socrates. It is difficult to know what to conclude about these early crossbow devices in Europe, but Needham believes they were introduced from China. Sicily, which was within easy sailing distance of Carthage, had Carthaginian colonies, and there were at least four prominent Pythagoreans from Carthage who were presumably known to Zopyros. And since the Carthaginians traded continually with the region of what is today Syria and Lebanon, there was certainly a route for transmission. Syria was known to the Chinese as Ta Ch'in, and trade existed between the two lands. Perhaps a Chinese crossbow arcuballista was smuggled out of China and sold at a high price as a hightechnology secret weapon. Or perhaps just a description of one was passed along the trade routes and copied by the Greeks (what is called 'stimulus-diffusion'). Or the Greeks may even have made the invention entirely independently, drawing inspiration as the Chinese had done from the simple bow-trap.

Heron of Alexandria has left an elaborate description of a crossbow artillery piece, though only the Germans have translated this fascinating work entitled *Belopeika*. Two ancient authors who wrote about these devices were Biton and E Vegetius Renatus (fourth century AD). But with the decline of Rome as a power, the crossbow principle fell into disuse and seems to have been more or less forgotten. The Romans had certainly used hand-held crossbows for hunting, but in the eleventh century the Byzantines were horrified to encounter their first crossbow in the hands of the first Crusaders. The Byzantine historian, the princess Anna Comnena, wrote of this new weapon, called the *tzaggra*:

The *tzaggra* is a barbarian bow hitherto quite unknown to the Greeks. [Description omitted.] ... They will pierce the stoutest metal armour, and sometimes wholly imbed themselves in a stone wall or other such obstacle when they strike it. In short, the *tzaggra* is a diabolical and murderous instrument, which fells men to the ground with such a shock that they do not even know what hit them.

The crossbow had made its appearance again in western Europe in the tenth century, after a gap of 500 years, and it is believed to have been used at the Battle of Hastings. So shocked were those who lived in the

Mediterranean region, that the Second Lateran Council of 1139 condemned crossbows under anathema of the Church, except for use against infidels. But 50 years later, Richard I (Lion Heart) took many of them on his Third Crusade. In 1521, Cortes used crossbows as one of his main weapons in subjugating what is now Mexico.

It is curious that the crossbow should have been used, though rarely, at an early period in Europe, and then have disappeared. This perhaps demonstrates something about the disruptions and lack of continuity of the European Dark Ages. The device may have survived as a hunting weapon for five centuries in the far west of Europe, to re-emerge in the tenth century as a weapon of war. Or it may, as Needham suspects, have been reintroduced a second time from China, perhaps through the Central Asian people known as the Khazars.

#### **GUNPOWDER**

NINTH CENTURY AD

Gunpowder first came to the attention of the West in the late twelfth century. By that time, the Chinese had carried its development through many stages and even perfected the barrel gun and the cannon. The evolution of gunpowder and its uses was therefore essentially complete before Europe had even heard of it.

Gunpowder was invented in China not by people seeking better weapons or even explosives, but by alchemists seeking the elixir of immortality. What greater irony could there be than that men wishing to find a drug to enable them to live for ever should instead find a simple substance destined to kill millions of people?

Before gunpowder could be developed, first it was necessary to recognize and obtain the most important of its three ingredients. This is saltpetre, the chemical name for which is potassium nitrate. It was completely unknown in the West until the Middle Ages, and because it generally forms natural deposits only in hot climates there is a considerable shortage of it in Europe, while China always had abundant local supplies of it. But it is not something which is just sitting there waiting to be used; it has to be recognized for what it is, differentiated from all other similar-looking chemical salts, and purified.

How is it possible to know when one has real

saltpetre, which looks more or less like any number of other chemicals? The potassium flame test is crucial for detecting saltpetre, because it burns with a violet or purple flame. This was being used to test for true saltpetre in China by at least the third century AD (2000) years before the West), the test being performed by putting a sample of the saltpetre on a piece of charcoal and watching it burn. Later, an even more important test was developed, which is described by Sheng Hsüan Tzu in his book of 1150, Illustrated Manual on the Subduing of Mercury (as quoted by the later scientist Li Shih-chen of the Ming Dynasty in the chapter on minerals in his famous 52-volume work, Compendium of Materia Medica):

If you heat a piece of white quartz and then put a drop of the saltpetre on it, it will sink in. The Taoist books say that saltpetre from Wu-Ch'ang (Udyana) can liquefy or dissolve all metals and minerals. If consumed it can prolong life. The places where it is produced have an extremely loathsome smell, so that birds cannot fly over them.... Pieces shaped like little goose quills are the best kind ... some of the saltpetre used nowadays is not natural saltpetre.... At Shang-ch'en and at Huai Chou and Wei Chou, all in Hopei Province [but nowadays in modern Henan Province], as Tsui Fang records in his book Wai Tan Pen Tsao, people scrape it up from the salty soil, and make it from the filtered drippings ... it is named 'solve-stone' because it can dissolve and transform all kinds of ores and minerals.

Here we see its initial attraction to the Chinese. Long before anyone had any idea that saltpetre could be used as an ingredient of the then still unknown gunpowder mixture, it was prized for its ability to liquefy ores and to dissolve otherwise indissoluble minerals, such as cinnabar, into watery solutions. Saltpetre was used for this purpose at least by the second century BC, as well as acting as a flux to promote metallurgical processes. Since the name 'solve-stone' goes back to the fourth century BC, it is likely that saltpetre's uses were appreciated then, though they were not specified in surviving texts until the second century BC.

When saltpetre finally came to the knowledge of the West, the Arabs (who were the first to learn of it) called it 'Chinese snow'. The oldest surviving mention

ABOVE (168) The figure on the right is firing a bombard, and this cave carving is the oldest known depiction of a gun in the world, dating back to 1128. I visited this carving together with Joseph Needham and Lu Gwei-Djen in 1986, in the extensive Buddhist cave complex at Dazu in Szechuan Province. It is in an extremely remote country area reached by ten hours of driving over rough dirt roads.

of it is in an Arab book of 1240 called *The Book of the Assembly of Medical Simples* by Abu Mohammed al-Malaqi Ibn al-Baitar. Although knowledge of gunpowder reached the West in the twelfth century, the formula for it was somewhat delayed and it was the end of the thirteenth century before saltpetre's use in gunpowder was known to the Arabs, and hence the Europeans. Until the eighteenth century, when sources in India were opened up by the British, saltpetre was in such short supply in Europe that the uses of gunpowder were much curtailed.

Another essential constituent of gunpowder is sulphur, and this too the Chinese were able to purify. Pure sulphur is mentioned in the Chinese book of the second century AD, *Pharmacopoeia of the Heavenly Husbandman*. Evidence from the eleventh century indicates that by that time the method of obtaining pure sulphur was by roasting iron pyrites ('fools' gold') piled up with coal briquettes in an earthen furnace. A still-head sent over the sulphur as vapour, after which it solidified and crystallized (from the conversion of the sulphide to oxide). The emperor issued an edict in 1067 banning the sale to foreigners of either

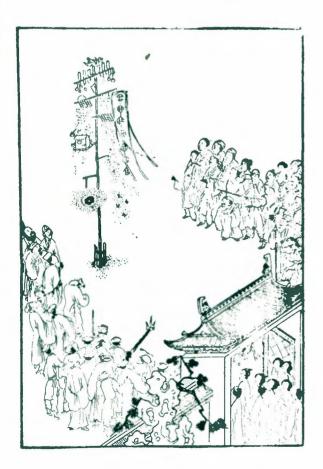

sulphur or saltpetre, and banning all private transactions in both commodities altogether. Large private enterprises in those commodities were thus put out of business, and the usual Chinese practice of nationalizing major industries and forming government monopolies was followed.

In the gunpowder mixture, whatever the proportions (which vary widely), it is the sulphur which lowers the ignition temperature to 250°C and, on combustion, raises the temperature to the fusion point of saltpetre (335°C). It also helps to increase the speed of combustion, but the explosive element in gunpowder may be said to be saltpetre, which burns merrily even on its own. This chemical contains much oxygen; whereas ordinary fires burn, that is, oxidize the fuel, by taking oxygen from the air, gunpowder burns by taking oxygen from the saltpetre within it, and which is ready to hand. And the more saltpetre in the gunpowder, the more explosive it becomes. Early Chinese gunpowders tended to contain about 50 per cent saltpetre, and thus were not truly explosive. For a really big explosion, about 75 per cent saltpetre is needed. The Chinese slowly edged their way upwards towards this daring proportion, which would eventually enable them to have all the bombs, grenades, land and sea mines which are described below (page 256).

With saltpetre, sulphur and the readily available carbon of charcoal and other substances all in their hands continually, it was inevitable that the alchemists would eventually put the three together and stumble upon gunpowder. Indeed, by the third century AD we find evidence that saltpetre and sulphur were being combined in the search for artificial gold. The famous alchemist Ko Hung produced a recipe in around 300 AD for mixing half a pound of sulphur with a pound each of saltpetre, mica, hematite, clay, and so forth, and heating them together to form a mysterious 'purple powder' which by projection would turn molten lead into gold, or something like it. And, he says, 'the same purple powder will at once turn heated mercury in an iron vessel into silver.' What the purple powder was remains uncertain, but one thing is certain - sulphur and saltpetre were both ingredients in an alchemist's formula at the beginning of the fourth century.

Even more to the point, Ko Hung gave a recipe for getting elementary metallic arsenic, which was also isolated by the Chinese centuries before its isolation in Europe. In this process, saltpetre, sulphur and carbonaceous material were all combined, getting very close to proto-gunpowder. The saltpetre oxidized the realgar (arsenic disulphide) into arsenious oxide, and the carbonaceous material then reduced this to volatile elementary arsenic vapours which, Ko Hung said, 'will arise like wisps of cloth, and arsenic sublimes as white as ice.' Needham believes that these early associations with arsenic may have been responsible for setting a pattern, whereby arsenic was routinely incorporated into Chinese gunpowder in later centuries, where its presence in bombs acted as a poison adding to the destructive effect of the explosions.

No textual evidence survives of any approximation to gunpowder mixtures for another 350 years. A book called *Methods of the Various Schools of Magical Elixir Preparations* records that around 650 the alchemist Sun Ssu-Mo made some preparations which included sulphur and saltpetre, and which were inflammable. But another 150 years were to pass before more such mixtures appeared. Chao Nai-An compiled a book about the year 808 entitled *Complete Compendium on the Perfect Treasure of Lead, Mercury, Wood and Metal* which mentioned a 'Method of subduing alum by fire'

involving the mixing together of two ounces each of sulphur and saltpetre with a third of an ounce of dried birthwort herb (Aristolochia). The dried herb would have contained sufficient carbon to make this mixture liable to ignite suddenly and burst into flames, though it would not actually have exploded. This has been confirmed by a modern experiment where the mixture was prepared. It may be that over the centuries since 300 AD, such inflammable mixtures were continually found and just as continually avoided as being too dangerous, and hence did not enter into the texts, which were concerned with useful (or ostensibly useful) recipes. But this is speculation. The fact is that five-and-a-half centuries passed after Ko Hung before Chinese alchemists recorded a formula which can be genuinely described as a gunpowder mixture. And so it is that we set 850 AD as the approximate date for the invention of gunpowder.

The first textual recording of a proto-gunpowder formula is found in a book entitled Classified Essentials of the Mysterions Tao of the True Origin of Things, preserved in the great collection of Taoist classics. It was attributed to Cheng Yin, the teacher of Ko Hung, but this is believed to be a fictional authorship, and the book is dated to about 850. The book contains thirty-five elixir formulae which are to be avoided as wrong or dangerous, three of these involving saltpetre. But the crucial passage reads:

Some have heated together sulphur, realgar (arsenic disulphide), and saltpetre with honey; smoke and flames result, so that their hands and faces have been burnt, and even the whole house where they were working burned down. Evidently this only brings Taoism into discredit, and Taoist alchemists are thus warned clearly not to do it.

It should be noted that the honey would have contained carbon, and the drier the honey the more the carbon. We do not know how long this sort of thing had been going on, but Needham takes the date

LEFT (169) A woodcut published in the 1643 edition of the popular novel *Chin P'ing Mei* (named after its three main female characters), showing a public fireworks display. To the left of the pole near the bottom is a spinning catherine-wheel. Fireworks were the first form of Chinese gunpowder to reach the West, in the late twelfth century. The Chinese knew how to make them in a wide variety of different colours.

ABOVE (170) The Chinese passion for fireworks has been continuous for about a thousand years. Here we see a display in modern Hong Kong during the National Day celebrations.

of this book, 850 AD, as the date of the first true appearance of what the Chinese called the 'fire-chemical', that is, gunpowder.

It was around the year 1040 that Tseng Kung-Liang published a true gunpowder formula for the first time in history. Certainly true gunpowder and its uses had been known by this time for at least a century. Tseng gives three gunpowder formulae for three different weapons: a quasi-explosive bomb to be hurled by a kind of catapult, a burning bomb with hooks which could catch onto wooden structures and set them on fire, and a poison-smoke ball for chemical warfare. The gunpowder in these was not explosive but rather what is called 'deflagrative', that is, it burned 'with a sudden and sparkling combustion, producing a "whoosh" like a rocket'. The bombs did

not yet contain enough saltpetre to explode. This would come later.

The first use of gunpowder in war was not, however, in anything so dramatic as an incendiary bomb. Around 919, we find it used in the form of a gunpowder-impregnated slow-match fuse for the ignition chamber of the flame-thrower. This hideous device (see page 254) sprayed enemies with burning gasoline. As it passed from the pump it was ignited by the gunpowder-impregnated fuse, so that sheets of flame descended upon them.

When explosive gunpowder did come, truly explosive bombs, rather than merely incendiary bombs, were produced in vast quantities. As the proportion of saltpetre in the mixture is increased, a point is reached where 75 per cent of the gunpowder is saltpetre – more or less the proportions found in 'modern' gunpowder. It is now past the point of mere explosion; one now gets detonation. When this stage was reached in China, barrel guns and cannon became

possible (see page 266). Upon ignition, gunpowder of this type suddenly produces 3000 times its bulk in gas, reaching temperatures of the order of 3880°C. The rapidity of the phenomenon is made possible by the fact that the oxygen is in the saltpetre within the mixture, so that no oxygen needs to be sucked in from the surrounding air.

All these stages, from alchemical accidents and singed Taoist beards through to the true barrel gun and cannon, had been reached by the Chinese before anyone in the West had ever even heard of gunpowder, let alone seen it in use. But what Westerners lacked in initial knowledge, they made up for in later enthusiasm.

#### THE FLAME-THROWER

TENTH CENTURY AD

The flame-thrower was not invented in the twentieth century, as most people would naturally assume. If one considers a flame-thrower to be a device capable of emitting a continuous stream of flame in warfare, it was invented by the Chinese by the tenth century AD. An earlier form, which might more properly be called a 'flame-squirter', was used in 675 by Callinicus in defence of Byzantium.

It had a 'siphon' which apparently pumped flame by means of a single-acting force-pump which was rather like a large syringe (invented in the West by Ctesibius in the third century BC). The proto-flame-thrower of the Byzantines was apparently incapable of ejecting a continuous stream of flame; it sent out a burst of flame, was repumped, and then gave another burst.

The reason for the superiority of the Chinese device, and the reason we consider it to be the first genuine flame-thrower, was the continuous stream of flame made possible by the Chinese invention of the double-acting piston bellows (see page 46), which was also used in chemical warfare by the early fourth century BC for spraying soldiers with clouds of poison gas (page 240). The superiority of Chinese metallurgy was also apparent here, as the flame-thrower was made of the very best cartridge-quality brass, containing 70 per cent copper.

What was it that the flame-thrower actually threw? What was burnt to make this stream of fire? According to Needham, it was either gasoline or kerosene, in other words, a 'distilled light fraction of petroleum'. The Chinese had stills for manufacturing this and they certainly used petroleum products (see page 89).

But there is no need to think that the Chinese actually

invented this, for J.R. Partington in his *History of Greek Fire and Gunpowder* (1960) concluded that the 'Greek Fire' used by the Byzantines in their flamethrower was the same substance. And Needham points out that 'Greek Fire came into China by about 900 AD.'

The first use of 'Greek Fire' in a flame-thrower in China appears to be in the year 904. Lu Chen, in his Historical Memoir of the Nine States, recounts an engagement of that date and says: 'Cheng Fan's men let off flying fire machines, which burnt the Lung-sha Gate...'. We have a far clearer account of flame-throwers in a description of the naval battle on the Yangtze River in 975, preserved by Shih Hsü-Pai in his book Talks at Fisherman's Rock:

Chu Ling-Pin as Admiral was attacked by the Sung emperor's forces in strength. Chu was in command of a large warship more than ten decks high, with flags flying and drums beating. The imperial ships were smaller but they came down the river attacking fiercely, and the arrows flew so fast that the ships under Admiral Chu were like porcupines. Chu hardly knew what to do. So he quickly projected petrol from flame-throwers to destroy the enemy. The Sung forces could not have withstood this, but all of a sudden a north wind sprang up and swept the smoke and flames over the sky towards his own ships and men. As many as 150,000 soldiers and sailors were caught in this and overwhelmed, whereupon Chu, being overcome with grief, flung himself into the flames and died.

There is another mention of flame-throwers in the same year, in the *History of the Southern T'ang Dynasty*, where we are told that a commander named Ts'ao Pin 'came down upon Chinling. He had large ships furnished with bundles of reeds saturated with thick oil, with the intention of taking advantage of the wind to start conflagrations.... But in urgent situations, then they used the machines to shoot the fire-oil forwards to resist the enemy.'

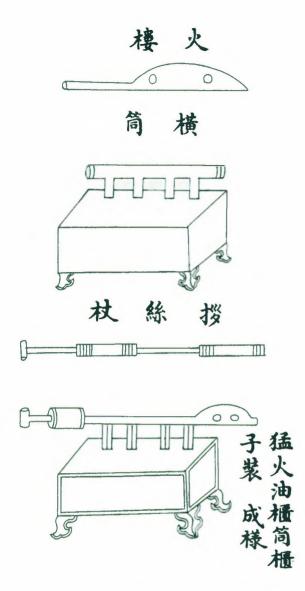

In a book of 1137 by K'ang Yü-Chih entitled *Dreaming of the Good Old Days*, we find a description of the storage and use of gasoline for flame-throwers. He speaks of 'a large reservoir more than 10 feet square in order to store "fierce fire oil", which he says 'should only be stored in real glass vessels.' He recalls:

I myself still remember the district commanders coming to it to study and practise water-combat with their troops, and to test the fierce fire oil. The opposite bank of the lake represented the fortified camp of the enemy. Those who were in charge of the oil sprayed it about, and as it was ignited it broke into a sheet of flame, so that the [fictitious] fortifications of the enemy were all in a short time completely destroyed. What is more, the oil had a secondary effect on the water, for all the water-plants were killed, and the fishes and turtles died.

The mention of ignition in the passage above brings us to the question: how was the ejected gasoline ignited as it left the flame-thrower? Obviously it could not be burning before it left, for then the man holding the machine would be destroyed by flames himself. The answer is that a lighted fuse was held in front of the nozzle, so that when the gasoline was squirted out, it was ignited after it was already on its way through the air. The fuse was impregnated with gunpowder; as mentioned in the account of gunpowder (page 250), this was the first military use of the substance. This gunpowder was so low in saltpetre content that it could not explode, but only sparked and burnt slowly in the fuse.

By 1044, the flame-thrower was standard issue to Chinese armies. A military encyclopedia of that date, Collection of the Most Important Military Techniques, gives drawings of a flame-thrower with design details (see Plate 172 (page 256). The text says: If the enemy comes to attack a city, these weapons are placed on the great ramparts, or else in outworks, so that large numbers of assailants cannot get through.' There is a lengthy description of the device, which commences:

On the right is the gasoline flamethrower. The tank is made of brass, and supported on four legs. From its upper surface arise four [vertical] tubes attached to a horizontal cylinder above; they are all connected with the tank. The head and tail of the cylinder are large, the middle is of narrow diameter. In the tail end there is a small opening as big as a millet-grain. The head end has two round openings 1½ inches in diameter. At the side of the tank there is a hole with a little tube which is used for filling, and this is fitted with a cover.

The description continues in meticulous detail, observing that with the action of the piston, 'the oil comes out through the ignition-chamber and is shot forth as blazing flame.' Needham has reconstructed the details of the mechanical operation of the flamethrower and concluded that it had 'two of the tubes secretly connected within the tank. Such a design is very compatible with the directions in the text that the machine was to be started with the piston-rod pushed fully forward, and it also agrees with the statement that the "two" communicating feed tubes are alternately occluded.' The flame-thrower gave a continuous jet of flame 'just as the double-acting piston bellows gave a continuous blast of air, and the most obvious way of effecting this was to have a pair of internal nozzles one of which was fed from the rear compartment on the backstroke'.

LEFT (172) An illustration of a Chinese flame-thrower, published in 1601, redrawn from an encylopedia of 1044. The Chinese invented the continuous flame-thrower in the tenth century, having known of the seventh-century spurting flame-thrower of the Byzantines via Central Asia. Here we see the tank standing on four feet, with the pump and ejector above it. Because the Chinese invention of a double-acting piston-bellows was used with this device, a continuous stream of flame could be emitted. The metal used was cartridge-quality brass.

## FLARES, FIREWORKS, BOMBS, GRENADES, LAND MINES AND SEA MINES

TENTH CENTURY AD

Fireworks existed in China before gunpowder was invented. Pieces of bamboo were thrown into fires and exploded as fireworks from at least 200 BC. Even after gunpowder fireworks were invented, the exploding bamboo was retained until modern times. Because a fireworks tradition already existed in China, the advent of gunpowder was seen as a natural progression.

The Chinese love to accompany celebrations with explosions. Here is a description of early fireworks from a book entitled *Dreaming of the Capital while the Rice is Cooking*, published in 1275 by Wu Tzu-Mu:

Inside the palace the fire-crackers made a glorious noise, which could be heard in the streets outside.... All the boats on the lake were letting off fireworks and fire-crackers, the rumbling and banging of which was really like thunder.

The Chinese rapidly developed every conceivable type of fireworks, including spinning catherine wheels and rockets (for the invention of the rocket see page 262). They also had coloured explosions, using a wide variety of special materials. They could obtain brilliant sparkling effects by combining steel dust or tiny shavings of cast iron, reduced to a powder, with the gunpowder. They used these effects in their Roman candles, which also preceded any made in the West. Blue-green flashes could be obtained by using indigo, white by using white lead carbonate, red by using red lead tetroxide, purple by using cinnabar, black by using lignite and soap-beans, yellow by using arsenical sulphides, and violet by using — of all things — cotton

fibres. No festivity in China ever lacked colour after the invention of gunpowder.

It has already been mentioned (page 251) that the first bombs were incendiary ones, using a gunpowder with insufficient saltpetre to cause a proper explosion. There was a long history of incendiary weapons of all kinds throughout the world, but when gunpowder became available in China, it was incorporated into incendiary weapons to deadly effect. No longer were such things as pitch and flammable resins and oils the main substance of incendiary arrows and bombs. In the tenth century, a whole new wave of incendiaries appeared, using gunpowder. Fire arrows were now tipped with little gunpowder bundles wrapped in paper and sealed with wax, and had gunpowder-impregnated fuses. We have seen how in 919 the flame-thrower used such fuses (page 255).

In 994 a gigantic force of 100,000 besiegers was driven away from the city of Tzu-t'ung using these gunpowder fire-arrows. These gunpowder projectiles would set fire to anything inflammable, whether tents, clothing, besieging engines, trench walls made of wood, stores of hay or food wagons. The commander Chao Hsieh is reported to have had a supply of 250,000 gunpowder-armed arrows in the year 1083; mass-production of these weapons was evidently in full swing.

By the first half of the eleventh century, a new kind of gunpowder bomb came onto the scene. Called a 'thunderclap bomb', this was truly explosive, and had a high percentage of saltpetre. It was enclosed in a weak casing of bamboo or paper and hurled from

trebuchets, which had previously been used to hurl great stones at enemy fortifications with slings, and then incendiary bombs. Thunderclap bombs were far more effective in starting fires; they also terrified the enemy's horses with explosive sounds, and many barbarian tribes were seriously demoralized by the noise alone, at first. These bombs either had fuses or were ignited by a red-hot poker just before being hurled.

Here is the eleventh-century description of how to make an explosive bomb:

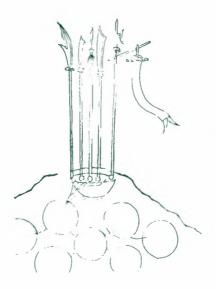

The thunderclap bomb contains a length of two or three internodes of dry bamboo with a diameter of 1.5 inches. There must be no cracks, and the septa are to be retained to avoid any leakage. Thirty pieces of thin broken porcelain the size of iron coins are mixed with 3 or 4 lb of gunpowder, and packed around the bamboo tube. The tube is wrapped within the ball, but with about an inch or so protruding at each end. A gunpowder mixture is then applied all over the outer surface of the ball.... A long red-hot iron brand is used to set off the thunderclap bomb, which produces a noise indeed like thunder.

This extract is from the Collection of the Most Important Military Techniques, published in 1044. There is an eyewitness account of the use of thunderclap bombs in fighting off a siege in the late eleventh century, written by the commander Li Kang: 'At night the thunderclap bombs were used, hitting the enemy well, and throwing them into great confusion. Many fled, howling with fright.'

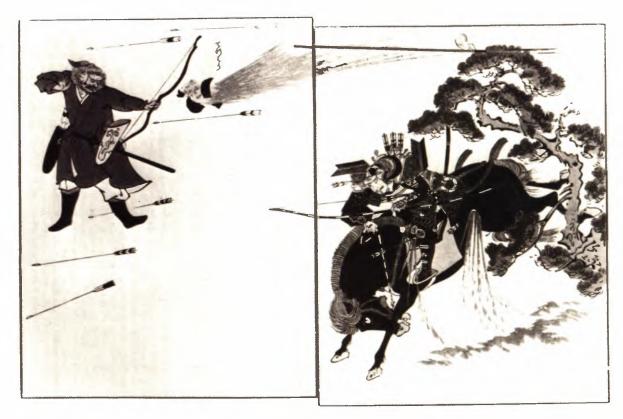

Thunderclap bombs also came in the form of grenades which could be hurled by hand. A scholar, Yuan Hao-Wen, recorded an extraordinary story in a book published in 1187, describing the use of thunderclap grenades by a hunter:

Towards the end of the Ta-Ting reign-period there lived north of T'aiyuan a certain hunter named T'ieh Li. One evening he found a great number of foxes in a certain place. So knowing

the path that they followed, he set a trap, and at the second watch of the night he climbed up into a tree carrying at his waist a vessel of gunpowder. The coven of foxes duly came

LEFT (173) A fourteenth-century land mine booby-trap called 'the underground sky-soaring thunder'. A group of halberds, pikes and banners is stuck into the ground as a tempting trophy. When the enemy approaches to seize them, he steps on a mechanism which lights a fuse, and he is blown up by the land mines buried underground.

ABOVE (174) The only known picture of a thirteenth-century bursting bombshell, this woodcut published in 1293 comes from a Japanese book describing the Mongolian invasion of Japan in 1274. Although the Japanese obtained the idea of bombs from China, the bomb shown here, a castiron 'thundercrash' type, is probably a Chinese one, since the Mongols were ruling China by this time. It was two-and-a-half centuries before bombs of this type appeared in Europe.

under the tree, whereupon he lit the fuse and threw the vessel down; it burst with a great report, and scared all the foxes. They were so confused that with one accord they rushed into the net which he had prepared for them. Then he climbed down the tree and killed them all for their fur.

This grenade would probably have been housed in a narrow-mouthed pottery vessel. As for lighting the fuse, the hunter probably used a match (see page 110).

The Chinese also invented flares, which they called 'signal bombs'. In 1276, when A-Chu was attacking Yangchow, flares were fired by the Chinese to send messages to distant troop detachments. These were soft-shelled bombs timed to explode in mid-air, possibly coloured like fireworks.

By 1221, we find in use a new type of bomb in China. Instead of being called a thunderclap bomb, it is called a thunder*crash* bomb. These bombs were

far more deadly because instead of having soft casings, they were real bombs in the sense we would recognize today, with casings of metal. This meant that they gave off deadly shrapnel, mutilating and blinding the enemy. Also, in order to burst the metal casings asunder, these new bombs were made of a gunpowder with even more saltpetre. No longer did this gunpowder merely explode: it detonated. Gunpowder of this strength was fully comparable with modern gunpowder, with about 75 per cent saltpetre in the mixture.

The thundercrash bombs appear first in the hands of the Chin forces at their successful siege of Ch'ichou. Here they defeated the Sung Chinese, who were gradually being forced southwards (the Chin themselves were being forced southwards in their turn by the Mongols who were at their back). The new bombs were in cast iron casings (cast iron having been invented in China, see page 44). Chao Yü-Jung records: 'Their shape was like that of a bottle-gourd

with a small opening and they were made from cast iron about 2 inches thick.' It is thought that the same bombs were in the hands of the defenders, but because they lost the siege there is less information about them. These thundercrash bombs were said to make a noise like thunder, shaking the walls of houses and killing and wounding countless people. They are not called thundercrash bombs in this account. The first use of that term occurs ten years later, in 1231, when the Chin were themselves besieged by the Mongols in a city in Shansi Province. The Chin general escaped by sea down the Yellow River with three thousand of his men, pursued along the northern bank by the ferocious Mongols who kept up a steady rain of arrows upon him. The Chin dynastic history tells us:

But the Chin ships had on board a supply of those bombs called 'thunder-crash' missiles and they hurled these at the enemy. Flashes and flames could distinctly be seen ... eventually the Chin fleet broke through, and safely reached Tung-kuan.

In the following year, 1232, the Mongols took the capital in the north, K'aifeng, from the Chin. In the Chin history we read of the siege:

Among the weapons of the defenders there was the heaven-shaking thunder-crash bomb. It consisted of gunpowder put into an iron container; then when the fuse was lit and the projectile shot off there was a great explosion the noise whereof was like thunder, audible for more than 100 li [tens of miles], and the vegetation was scorched and blasted by the heat over an area of more than half a mon [many acres]. When hit, even iron armour was quite pierced through. Therefore the Mongol besiegers made cowhide sheets to cover their approach trenches and men beneath the walls, and dug as it were niches each large enough to contain a man, hoping that in this way the Chin troops

so that no one durst come near. These thundercrash bombs and flying fire-spears were the only two weapons that the Mongol soldiers were really afraid of.

above would not be able to do anything about

it. But someone up there suggested the technique

of lowering the thunder-crash bombs on iron

chains. When these reached the trenches where

the Mongols were making their dug-out, the

bombs were set off, with the result that the

cowhide and the attacking soldiers were all

blown to bits, not even a trace being left behind.

Moreover, the defenders had at their disposal flying fire-spears. These were filled with

gunpowder, and when ignited, the flames shot

forward for a distance of more than ten paces,

RIGHT (175) A picture of a very nasty Ming Dynasty device called a Wasps' Nest Fire Bomb. It spewed out pellets, barbs, and spikes which 'stung', in addition to the usual fire and explosives. This engraving dates from circa 1500 and was reprinted from the original block in 1883. (Collection of Robert Temple.)

RIGHT (176) A seventeenth-century Chinese bomb with fuse, of a kind used for firing into the clouds in an attempt to precipitate rain. The gunpowder is wrapped in paper and sealed with wax, and the fuse is impregnated with gunpowder.

The Mongols eventually destroyed the Chin power and moved on to attack the Sung Chinese who had long since set up a new capital in the south; this dynasty is called the Southern Sung. However, the Southern Sung were not very well prepared for the Mongol onslaught. A scholar official named Li Tseng-Po bemoaned this in 1257:

As for the weapons for attack by fire, there are or should be several hundred thousand iron bomb-shells available. When I was in Chingchow they were making one or two thousand of them a month, and they used to despatch to Hsiang-yang and Ying-chou ten or twenty thousand a time. Yet now at Chingchiang we have no more than 85 iron bomb-shells, large and small, 95 fire-arrows, and 105 firelances. This is not sufficient for a mere hundred men, let alone a thousand, to use against an attack by the Mongol barbarians. The government supposedly wants to make preparations for the defence of its fortified cities, and to furnish them with military supplies against the enemy, yet this is all they give us. What chilling indifference!

The only surviving contemporary picture of a bursting bombshell of the thirteenth century is a Japanese drawing showing a Chinese-style thundercrash bomb in a cast iron casing exploding in mid-air. The drawing was made in 1293. As for cast iron bombshells in Europe, the earliest record of their definite occurrence and use dates from 1467, exactly 246 years later than the earliest recorded use of them in China.

Over the coming years, the Chinese developed a bewildering variety of different bombs with specialist

uses, some packed with what military writers today call antipersonnel material, to increase the shrapnel effect. There were also many poison bombs, gaseous bombs, and bombs filled with human excrement. Some of the best-known bombs and grenades were 'the bone-burning and bruising fire-oil magic bomb', the 'magic fire meteoric bomb that goes against the wind', the 'dropping-from-heaven bomb', the 'bee-swarm bomb', the 'match for ten thousand enemies bomb', the 'flying-sand magic bomb releasing ten thousand fires' and the 'wind and dust bomb'.

By 1277 the Chinese had developed bombs to the point of

their being used as land mines. From that year we have reports of an 'enormous bomb' being used which was more like a land mine than an actual bomb. And by the middle of the fourteenth century descriptions of how to make land mines were actually being published in books, which is a sure sign that they were no longer secret. Here is one such description:

The mine, made of cast iron, is perfectly spherical in shape. It holds one peck or five pints of black powder, depending on its size. The 'magic gunpowder', 'poison gunpowder' and 'blinding and burning gunpowder' compositions are all suitable for use in this device. Hard wood is used for making the wad, which carries three different fuses in case of defective connection, and they join at the 'touch hole'. The mines are buried in places where the enemy is expected to come. When the enemy is induced to enter the mine-field the mines are exploded at a given signal, emitting flames and fragments and a tremendous noise.

This is from *The Fire-Drake Artillery Manual*, which was published in 1412 and contains some mid-fourteenth-century material. Another mid-fourteenth-century land mine recorded in the same book was actually a network of mines called 'the ground-thunder explosive camp', described as follows:

These mines are mostly installed at frontier gates and passes. Pieces of bamboo are sawn into sections 9 feet in length, all septa in the bamboo being removed, save only the last; and it is then bandaged round with fresh cow-hide tape. Boiling oil is next poured into the tube and left there for some time before being removed. [This is thought to have been to seal the bamboo against damp from the ground as well as insect attack, to which bamboo is notoriously prone.] The fuse starts from the bottom of the tube, and black powder is compressed into it to form an explosive mine. The gunpowder fills up eight-tenths of the tube, while lead or iron pellets take up the rest of the space; then the open end is sealed with wax. A trench 5 feet in depth is dug for the mines to be concealed. The fuse is connected to a firing device which ignites them when disturbed.

The same also describes a 'self-tripped trespass mine':

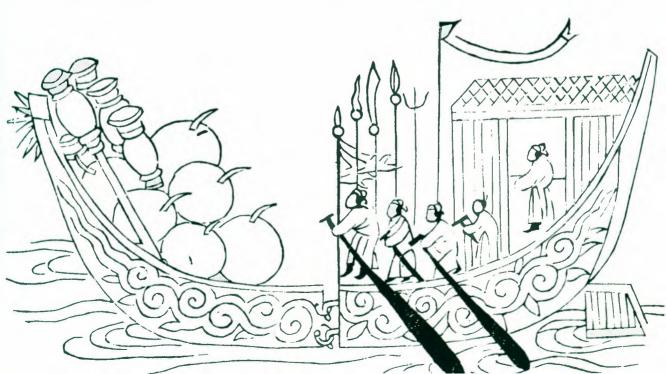

It is made of iron or rock, or even porcelain or earthenware, with a cavity inside, very like the explosive mine mentioned above. Outside, the fuse runs through a series of 'fire-ducts', which connect together several of these devices installed at strategic points. When the enemy ventures onto ground containing one of these mines, all the others are set to explode quickly one after another.

Yet another land mine described in the same book, called 'the Supreme Pole combination mine', featured a battery of eight little guns pointing in different directions, all set off by an automatic trigger mechanism. It was more in the nature of a boobytrap to be laid in mountain passes, dating from the early fourteenth century.

Some of the trigger-mechanisms of Chinese land mines remained secret until the seventeenth century, when descriptions of them were finally published. Some involved arrangements of flint and steel, which when automatically triggered by a cord would strike and send sparks onto tinder, which then lit gunpowder-impregnated fuses leading to the mines. There were at least two steel wheel systems. These land mine triggers would seem to be the ancestors of the flintlock rifle, going back to 1360 at least.

In Europe, the wheel-lock musket first appeared in a drawing by Leonardo da Vinci in 1500, but the

BELOW (177) An articulated barge of the late sixteenth century, used as a minelayer. The front is loaded with sea mines. When the barge approaches the target, the front portion is detached and left with a time fuse burning, while the men in the rear portion quietly row away.

first actual example to be recorded dates from 1526. And the first European flintlock did not appear until 1547. Needham believes that the flint and steel land mine triggers of China were the direct forebears of these European mechanisms, though perhaps transmitted by 'stimulus-diffusion', which is the transmission of an idea or description rather than an actual object. The first appearance of land mines in Europe is thought to have been in the war between Pisa and Florence in 1403. And the first European land mines using triggers for ignition at a distance were developed by Samuel Zimmermann of Augsburg in 1573.

The Chinese did not restrict themselves to land mines. They also invented sea mines. The Fire-Drake Artillery Manual gives this description:

The sea mine called the 'submarine dragonking' is made of wrought iron, and carried on a submerged wooden board, appropriately weighted with stones. The mine is enclosed in an ox-bladder. Its subtlety lies in the fact that a thin incense-stick is arranged to float above the mine in a container. The burning of this joss-stick determines the time at which the fuse is ignited, but without air its glowing would of course go out, so the container is connected with the mine by a long piece of goat's intestine through which passes the fuse. At the upper end the joss-stick container is kept floating by an arrangement of goose and wild-duck feathers, so that it moves up and down with the ripples of the water. On a dark night the mine is sent downstream towards the enemy's ships, and when the joss-stick has burnt down to the fuse, there is a great explosion.

This Chinese sea mine of the fourteenth century was thus two centuries earlier than the oldest known European plan for a sea mine, which was presented by Ralph Rabbards to Queen Elizabeth in 1574. The Chinese were still using sea mines in fighting against the British in 1856 on the Canton River.

The Chinese were thus not slow to exploit all the explosive potentials of gunpowder. We shall shortly see how they developed the barrel gun and the cannon, which were also implicit in the development of their 'fire-chemical'.

## THE ROCKET, AND MULTI-STAGED ROCKETS

ELEVENTH AND TWELFTH CENTURIES AD

The invention of the rocket in China seems to have been doubly inspired. On the one hand, incendiary fire-arrows gave way to the idea of an arrow-shaft which could have a rocket mounted on it, so that arrows would no longer need to be fired from bows at all. On the other hand, inspiration came from a type of firework known as the 'ground rat' or the 'earth rat' which sped along the ground spewing flames from behind. We have an amusing story of a 'ground rat' running amok in the imperial palace in the year 1264:

When the Emperor Li Tsung retired, he prepared a feast in the Ch'ing-Yen Tien Palace Hall on the 15th day of the first month of the year in honour of his mother, the Empress-Mother Kung Sheng. A display of fireworks was given in the courtyard. One of these, of the 'ground-rat' type, went straight to the steps of the throne of the Empress-Mother, and gave her quite a fright. She stood up in anger, gathered her skirts around her, and stopped the feast. Li Tsung, being very worried, arrested the officials who had been responsible for making the arrangements for the occasion, and awaited orders from the Empress-Mother. At dawn next day, he went to apologise to her, saying that the responsible officials had been careless, and took the blame upon himself. But the Empress-Mother laughed and said, 'That thing seemed to come specially to frighten me, but probably it was an unintentional mistake, and it can be forgiven.' So mother and son were reconciled and just as affectionate as before.

There were also 'water rats', fireworks of this type which were tied to floats or little skis and went skidding across lakes and ponds in firework festivals. Chou Mi in his book *Customs and Institutions of the Old Capital*, written in the middle of the thirteenth century but describing festivities of the mid-twelfth century, speaks of fireworks of those days:

Some of these were like wheels and revolving things, others like comets, and others again shooting along the surface of the water. The latter were water rats, but comet-like fireworks were a type of rocket. Around 1150 it crossed someone's mind that an 'earth rat' or 'water rat' tube attached to a feathered stick would constitute a rocket-arrow equipped to fly without being launched from a bow. We even have an early description of how to make one:

One uses a bamboo stick 4 feet 2 inches long, with an iron or steel arrow-head 4½ inches long smeared with poison; and some smear that on the rocket-tube too. Behind the feathering there is an iron weight four-tenths of an inch long. At the front end there is a carton tube bound onto the stick,

where the 'rising gunpowder' is lit and it is oiled to prevent its getting wet. When you want to fire it off, you use a frame shaped like a dragon, or else conveniently a tube of wood or bamboo to contain it or launcher boxes of different kinds.

Another book gives further details about the crucial invention of the balancing weight:

An iron weight is fixed at the rear end of the rocket-arrow, behind the feathering, of such a mass that the fulcrum of the balance is situated just four finger-breadths away from the mouth of the rocket-tube.

These counter-weights enabled the rockets to travel considerable distances by holding down their rear ends in order to avoid the rocket arrow's tipping down and hitting the ground.

The same early text adds the even more remarkable description of the need to bore a hole in the centre of the gunpowder (a dangerous business; the boring tool needed to be moistened continually with water to avoid explosion from the friction).

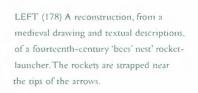

When the gunpowder burned, there

would be equal areas of combustion surface along an internal cavity in the powder, which is a basic requirement for an efficient rocket. The text tells us:

If the hole is straight-sided [i.e., parallel with the walls of the tube] the arrow will fly straight; if it is slanting the arrow will go off at a tangent. If the hole is too deep the rocket will lose too much flame at the rear, if it is too shallow, it will not have enough strength, so the arrow will fall to the ground too soon. If the rocket-tube is 5 inches long, the cavity must extend into it some 4 inches. The shaft has to be absolutely straight, and the rocket-tube and end-weight of the arrow must

balance perfectly when suspended two inches from the neck, or throat [i.e., nozzle], of the rockettube, while the feathering should be almost as long as the rockettube itself.

There were even diagrams published showing the boring tool, and illustrating the cavity. All of these developments had taken place during the twelfth and thirteenth centuries. By 1300 at the latest, the furthest refinement of rockets had taken place whereby the orifice of the rocket-tube was constricted to increase the flowvelocity of the issuing gases, giving greater power. This choke or nozzle thus represented the 'Venturi-tube effect', which is one of the most elementary principles of aerodynamics since it gives the explanation for the occurrence of lift in connection with airplane wings. The principle was formulated in Europe by G. B. Venturi (1746-1822). The Chinese were therefore about 500 years in advance of him in their use of the principle.

RIGHT (179) Rockets were invented in China by the eleventh century, and were commonly strapped to arrows with poisoned tips. Here we see portable basketwork rocket-launchers in use in the fourteenth century. These rockets had a range of 200 yards or more. The launchers and rockets were not heavy, and were frequently carried by large numbers of foot soldiers. Tens of thousands of rockets were often fired during a single battle.

The gunpowder used in these early Chinese rockets is thought to have been about 60 per cent saltpetre. There were various mixtures, of which the names but not the proportions have survived: 'wind-opposing gunpowder', 'flying-in-the-air-gunpowder', 'flying gunpowder', and so on. Needham believes that the proportions were suppressed for the sake of military secrecy.

These rockets could fly between 500 and 1150 yards, though during the fourteenth or fifteenth century a device called the 'flying powder tube' was invented, which is said to have flown by rocket power to the enemy, dropping an explosive charge of poison and being flown back by a second rocket lit by a fuse. This device, which in theory could be re-used indefinitely, probably hardly ever worked. It was difficult enough controlling the flight direction of rockets, without also having to rely on their correct return. But it was certainly a bold and ingenious idea.

It soon became obvious to the Chinese that setting off the occasional rocket on its own was insufficient. They needed batteries of them. By fixing them within frames of rocket-launchers, they could direct them more reliably. And by making the frames take batches of them at once, barrages of rocket fire could and did wreak great havoc in warfare. There were even handheld portable rocket launchers woven of basketwork. These conical basket launchers would not have outlasted one mass firing, but were easily replaceable; they were really the medieval equivalent of the bazooka so widely used in the Second World War.

The wheelbarrow (invented in China; see page 95) was regularly used to hold portable batteries of rocket launchers. These were called 'fire-frame combatvehicles'. Wonderfully evocative names were given to the different types of rocket launchers: 'Mr Facing-Both-Ways rocket-arrow firing basket', 'Five-tigers-springing-from-a-cave rocket-arrows', 'Pack of one hundred tigers running together', 'Covey of hawks catching rabbits', 'Leopard pack unexpectedly scattering',

'Bees' nest', and 'Forty-nine simultaneously fired rocketarrows'. The splayed rocket launchers had internal diaphragms with holes in them to keep the rockets apart, and the launchers widened at the top from a narrower base, to ensure a wide area of dispersion of the points of impact of the rockets. An early text gives the description of one of the smaller portable ones:

The small bamboo rocket-arrow tube:

Each tube holds ten short rocket-arrows, only 9 inches long, and poison is applied to the head of each. The total weight of the tube and its contents does not exceed 2 pounds, and each soldier can carry four or five of them on its sling easily. The enemy would not know exactly what they were transporting. At a distance of some 170 yards away, the rocket-arrows are all fired as one. These arrows, though small, are fast, and the enemy cannot avoid them; so one soldier can do as much harm with these arrows as several dozen others using more conventional arms. These rocket quivers can be carried by the personal guards of the commander, or by the detachment

of soldiers surrounding the flag, or else by men scattered among ordinary fighting units. The rocket-arrows should be tested to ensure that they can penetrate thin wooden planks. If the bamboo tube is slightly raised at the time of firing, the arrows can reach over 340 yards. This weapon should not be overlooked just because the arrows are so small.

Descriptions of rocket-launchers in medieval Chinese books tell of batteries which could each dispatch 320 rockets at a single moment. These consisted of four 'long-serpent' rocket launchers in rows on wheelbarrows together with two rectangular wooden 'hundred-tiger' rocket launchers, one on either side. During the Ming Dynasty there is a battle account of a hundred of these operating together in an engagement. Such a super-battery was theoretically capable of launching 32,000 rockets at a single time, and during the course of a battle must have used up roughly a million rockets.

Stabilizing devices for rockets in flight were introduced by the Chinese not long after 1300, and are recorded in *The Fire-Drake Artillery Manual* published in 1412 but incorporating material a century older. These took the form of fins and wings, so that the result looked like a bird with rockets strapped under its belly. The text says:

The 'flying crow with magic fire' winged rocket bomb:

The body of the bird is made of fine bamboo laths or reeds forming an elongated basketwork, in size and shape like a chicken, weighing over 1½ pounds. It has paper glued over to strengthen it, and it is filled with explosive gunpowder. All is sealed up using more paper, with head and tail fixed on before and behind, and the two wings nailed firmly on both sides, so that it looks just like a flying crow.

Under each wing there are two slanting rockets. The fourfold branching fuse, connected with the rockets and about a foot long, is put through a hole drilled on the back of the bird. When in use, this main fuse is lit first.

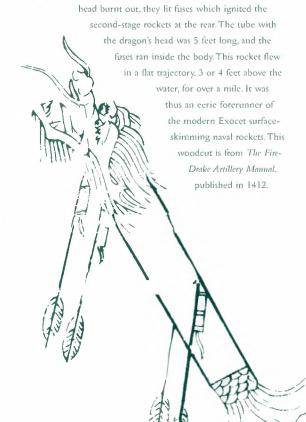

The bird flies away more than 1000 feet, and when it eventually falls to the ground, the explosive gunpowder in the cavity of the bird is automatically lit, and the flash can be seen miles away. This weapon is used against enemy

encampments to burn them, but also at sea to set ships on fire. It should never fail to bring victory.

It will immediately be obvious how strong a resemblance this weapon bears to the notorious V-1 rockets of the Second World War. As in the case of the V-1, there was little control over where the bomb might drop and explode when the rockets burned out. This is the world's oldest winged rocket. There were others, including a flying grenade called the 'free-flying enemy-pounding thundercrash bomb', which was a flying bomb in a cast iron casing which also gave off poisonous smoke and spilled out poison-tipped calthrops — sharp pointed objects on which men and horses would tread.

Multi-stage rockets in China go back to the early fourteenth century. We have already come across one which was supposed to fly over the enemy, drop an explosive charge, and fly back on a second rocket. Here is a description from *The Fire-Drake Artillery Manual* of the automatic lighting by a fuse of the

BELOW (180) The first of all multi-stage rockets, the 'fire-dragon issuing from the water', of the early or mid-fourteenth century, which was used in naval engagements. When the rockets near the

second stage of a rocket called 'the fire-dragon issuing from the water':

A tube of bamboo 5 feet long is taken, the septa removed, and the nodes scraped smooth with an iron knife. A piece of wood is carved into the shape of a dragon's head and fitted on at the front, while a wooden dragon tail is made for the rear end. The mouth must be facing upwards, and in the belly of the dragon there are several 'mysterious mechanism rocket-arrows'. At the dragon head there is an opening through which go all the fuses of the rockets inside.

Beneath the dragon-head on both sides there are two big rocket-tubes.... Their fuses and orifices should face downwards and backwards, and their front ends must face upwards and forwards; and they are fixed tight to the body by bands of hempen cloth secured with skin- and fish-glue. The fuses of the rocket-arrows within the belly lead out from the head of the dragon, and they are divided into two. Oiled paper is used to make them firm, and they are so arranged as to be connected with the front ends of the outside rocket-tubes. And under the tail of the dragon on each side there are also two big rockettubes, fastened in the same style. The fuses of the four rockets are twisted into a single one. In a naval battle, the apparatus can fly 3 or 4 feet above the water.

Upon lighting it will fly over the water as far as 1800 yards [just over a mile]. At a distance it really looks like a flying dragon coming out of the water. When the gunpowder in the rocket-tubes is nearly all finished, that in the rocket-arrows within the belly is ignited, so that they fly forth, destroying the enemy and his ships. It can be used either on land or on sea.

This strange multi-stage rocket was a forerunner of the modern Exocet, operating in the same way by skimming the water for a long distance and hitting a ship.

Rockets thus seem to have been invented in China about 1150, and they were used in warfare by at least 1206, in particular by the Sung Chinese in their defence of Hsiangyang against the Chin. As fireworks, they were in use in 1180 at Hangchow, the Southern Sung capital, as we have seen in the account by Chou

Mi. 'Earth rats', which were simple random ground firework-rockets, were probably the first rockets actually used in warfare at some time before the siege just mentioned. By about 1280, the Arab Hasan al-Rammah was already describing rockets as 'Chinese arrows'.

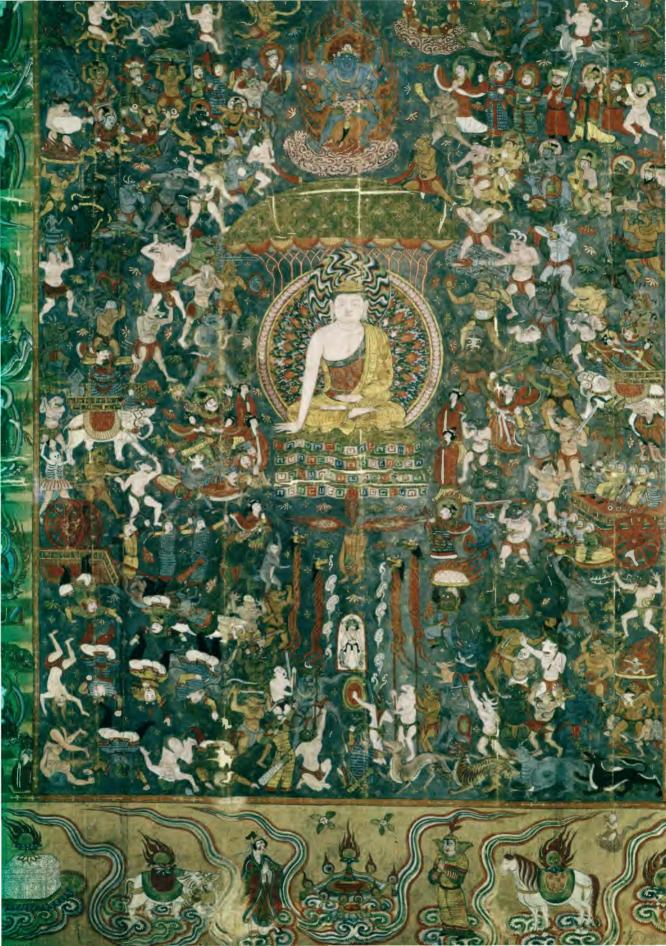

When did rockets first appear in the West? They are first mentioned in connection with the Battle of Chioggia between the Genoese and the Venetians in 1380. They must have come to Italy with Italian travellers, in the wake of Marco Polo. By 1405, Konrad Keyser in his Bellifortis was able to write that a rocket must have a hollow space inside its charge and an arrow-shaft. The knowledge of rockets thus came to Europe much more rapidly than did most Chinese inventions. The delay was just over two centuries. But it was only in the twentieth century that liquid-fuel rockets were developed, which give the promise to mankind of colonizing outer space. The eventual use of rockets to take man in great numbers beyond his own world leads Needham to believe that the rocket was probably China's most important invention, and its greatest technological contribution to mankind.

## GUNS, CANNONS, MORTARS AND REPEATING GUNS

THIRTEENTH CENTURY AD

About 905 AD the first 'proto-gun', called a fire-lance, was invented in China. The world's oldest depiction of a 'gun' is in a detail from a silk banner painted in the middle of the tenth century (see Plate 181 (opposite)). Buddha is meditating, and the demons of the evil goddess Mara the Temptress are trying to distract him. A grenade is about to be thrown at him while a demon with three snakes issuing from its head fires at him with a fire-lance. This incontrovertible physical evidence dates this invention no later than 950, much earlier than its first textual mention.

OPPOSITE (181) The world's oldest pictures of a gun and a grenade, in a painted silk banner of the mid-tenth century found at Tunhuang. The banner shows the assault of Mara the Temptress and her demons on the meditating Buddha; they are seeking to distract him from his attainment of understanding of the nature and mechanism of the universe, and to prevent his enlightenment. To the Buddha's top right one demon holds a proto-gun in the form of a fire-lance, whilst another just below brandishes a weak-casing bomb, from which flames have already begun to emerge. (Musée Guimet, Paris.)

RIGHT (182) A bronze Chinese cannon which, according to its inscription, was cast during the Ming Dynasty (ended 1644). Its calibre is 5½ inches; length 7 feet 10 inches. (Royal Artillery Institution, Woolwich.)

At first the fire-lance was essentially a Roman candle firework tied to a spear, but it was more powerful than a mere firework. In fact it acted as a five-minute flame-thrower, and it could kill, blind, or maim. It was particularly useful for defending city walls against besiegers. Large numbers of fire-lances were wheeled round in trolleys of several layers, so that when the five minutes were up the defending soldier would be passed another fire-lance in order to keep up the fire. A firelance would also set on fire the clothes of an enemy, or his besieging engines, or his tents. Even after the invention of the true gun, fire-lances remained popular and in fact were used right up to the middle of the twentieth century in China as protection against pirates who tried to board ships. In Europe, the fire-lance seems to have been used for the last time in the first siege of Bristol during the English Civil War in 1643; by the second siege, in 1645, it had been abandoned.

Fire-lances went through many improvements. Having started as lengths of bamboo tube which

simply spurted fire, they progressed to metal barrels. Many projectiles were fired from them, though not true bullets, since the projectiles did not perfectly fit the bore of the barrel (which is necessary for a true gun). Any old bits of broken pottery, stones, and iron or steel chips or balls, would be blown out of a firelance in a deadly swarm to splatter the unfortunate enemy. Clouds of projectiles could effectively be shot out 30 or 40 yards, and it was common practice to include poisonous chemicals in the gunpowder, so that enemies were blasted with arsenic and other lethal substances. But of course, this could not be done if the wind blew in the wrong direction! Firelances also frequently spewed out arrows with poisoned tips.

In 1233, the Mongols were besieging the Chin, who launched a daring night raid using fire-lances. We are told in the dynastic history:

On the fifth day of the fifth month they sacrificed to Heaven, secretly prepared firelances, and embarked 450 Chin soldiers outside the south gate, whence they sailed first east and then north. During the night they killed the enemy guards outside the dykes, and reached the Wang family temple.... Kuan-Nu divided his small craft into squadrons of five, seven and ten boats, which came out from behind the defences and caught the Mongols both from front and rear, using the firespouting lances. The Mongols could not stand up to this and fled, losing more than 3500 men drowned. Finally their stockades were burnt, and our force returned.

The fire-lance doubled as a pike in close combat, as we learn from this account of a battle in 1276:

At daybreak Chiang Tsai, seeing that Shih Pi's troops were few, pressed an attack, but Shih Pi resisted furiously. Two Sung cavalrymen rushed at him to pierce him with fire-lances, but he so defended himself with his sabre that to left and right every man fell; and he himself personally killed more than one hundred.

Later fire-lances dropped their spear-points, especially when they had progressed to stronger and longer metal barrels. There were always many kinds to choose from, for different purposes.

An artillery piece evolved from the fire-lance, as well as a gun which fired an ill-fitting shell, and was hence not a true gun. Since there is no specific name for these proto-cannons, Needham has christened them 'eruptors' – and erupt is what they did. Like fire-lances, they spewed forth fire and flame mixed with poisons and assorted bits and pieces. They fired arrows, pellets, stones and cannon balls. Some of them even fired exploding canisters with attached fuses which blew up after landing.

Should anyone think these fire-lances and eruptors were just noisy toys unlikely to cause much damage, it pays to read these remarks from the mid-thirteenth century about a 3-foot-long fire-lance which fired arrows and was called the 'single-flight magic-fire arrow':

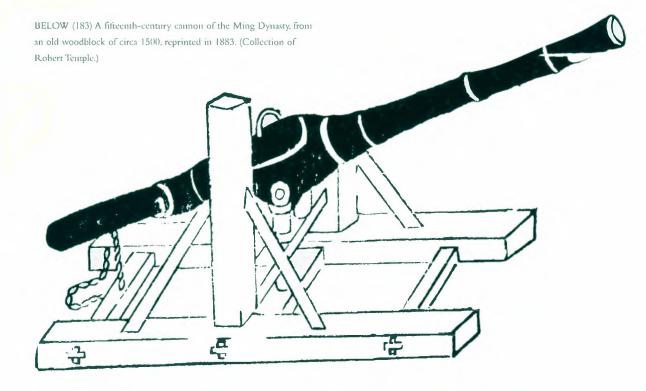

Use a barrel 3 feet long cast from high-grade bronze, and designed to take only a single arrow. Put 0.3 ounces of 'blinding gunpowder' as charge into the barrel before firing, whereupon the arrow is sent flying like a fiery serpent, with a range of between 200 and 300 paces. It can pierce the heart or the belly when it strikes a man or a horse, and can even transfix several persons at once.

Fire-lances with several barrels were frequently used, and were built so that when one fire-tube had exhausted

itself, a fuse ignited the next, and so on. One triple-barrelled fire-lance was called 'the triple resister', another was called 'the three-eyed lance of the beginning of the dynasty'. Several old woodcuts of these weapons survive, so that we know what they looked like and how they were constructed. One curious weapon was the 'thunder-fire whip' – a fire-lance in the shape of a sword, 3 feet 2 inches long and tapering into a muzzle. It discharged three coin-sized lead balls. An even stranger one was the 'vast-as-heaven enemy exterminating Yin—Yang shovel' which had a broad crescent-shaped blade at its end, and emitted poison as well as flames and lead pellets.

Certainly one of the most ingenious and useful fire-lances was the 'mattock gun'. It was fixed at right angles to a pole and could be hoisted to the top of the battlements while a hidden operator crouched behind and fired at besiegers coming over the wall. Besides flames, it shot six or seven pellets at a time from its metal barrel.

There were also huge batteries of fire-lances which could be fired simultaneously from mobile racks. One such was called 'the ingenious mobile ever-victorious poison-fire-rack', and it seems to have originated in the fourteenth century. A great frame with several wheels would hold many layers of sixteen fire-lances one after the other. It took ten men just to light all the fuses at once. A quaint description of its use in defending a besieged city relates:

When the enemy approaches the gate, all the weapons are fired at a single moment, giving a noise like a great peal of thunder, so that his men and horses are all blown to pieces. You can then open the city-gate and, relaxing, talk and laugh as if nothing had happened; this is the very best device for the guarding of cities.

Since these fire-racks were highly mobile, they were probably the earliest form of proto-tank, though of course no one was inside them. The blast from a fire-rack containing perhaps 200 fire-lances fired at once is hardly to be imagined, and the men operating them must have gone deaf very soon. The nearest thing to the fire-rack in modern times is perhaps the Russian 'Stalin-Organ', though this is used to launch rockets.

Yet another variation on the fire-lance was the 'one-eyed magically-efficient gun', which was a swivel gun. It had a metal barrel and wooden handle, and was inserted into one of three rings on a pole thrust into the ground on a spike to keep it steady. The swivel or forked rests later used in Europe with early muskets may have originated from this weapon.

The earliest evidence we have of fire-lances in Europe is from a Latin manuscript dated 1396, 450 years later than the Chinese version. It depicts them vividly, and contains a very dramatic picture of a mounted horseman charging ahead with a long, blazing fire-lance in his right hand. The Chinese protocannons – the 'eruptors' – appeared in the thirteenth century. The Fire-Drake Artillery Manual of 1412 describes one:

The shells are made of cast iron, as large as a bowl and shaped like a ball. Inside they contain half a pound of 'magic' gunpowder. They are sent flying towards the enemy camp from an eruptor; and when they get there a sound like a thunder-clap is heard, and flashes of light appear. If ten of these shells are fired successively into an enemy camp, the whole place will be set ablaze and his men will be thrown into confusion. You can use any kind of gunpowder in the shells – blinding powder, flying powder, violent powder, poison powder, bruising and burning powder, and smoke-screen powder, according to the circumstances.

Chang Hsien wrote a poem called 'The Iron Cannon Affair' in the year 1341, which describes an eruptor in operation:

The black dragon lobbed over an egg-shaped thing
Fully the size of a peck measure it was,
And it burst, and a dragon flew out with peals of thunder rolling
In the air it was like a blazing and flashing fire.
The first bang was like the dividing of chaos in two,
As if mountains and rivers were all turned upside down....

Just as the multi-barrelled fire-lance and the eruptors were ingenious innovations, so was the 'multiple bullets magazine eruptor'. Undoubtedly the idea of a magazine of projectiles had occurred to someone because of the widespread use of magazines on repeating crossbows. The eruptor was 4 feet 5 inches in length and made of cast bronze. A magazine a foot long, containing about a hundred lead balls, fed into it from the side as it spewed out flame. When the

ABOVE (184) A fourteeth-century bomb in the process of exploding. This one contains poisons and iron calthrops (small triangular spiked objects intended to litter the ground and wound the feet of men and horses).

Reproduced from The Fire-Drake Artillery Manual of Gunpowder Weapons, 1412.

eruptor was at rest the barrel was rotated, enabling the magazine to fall out and be loaded. Then, as firing began, the barrel would be rotated back again and the pellets would start falling down into the flames and be shot forth – the world's first repeating-cannon! It must be stressed, however, that only the projectiles could be termed 'repeating', not the charge.

A naval version of the eruptor fired 'chain-shot'. This consisted of two cannon-balls joined together by a chain or an iron bar. When fired from an eruptor, these rotated at great speed through the air, smashing the spars and rigging of an enemy ship and clearing its upper deck of men.

The gunpowder in these eruptors and fire-lances usually had 60 per cent of saltpetre in its composition, as was the case with rockets (see page 264). For the true gun, higher percentages of saltpetre were necessary between 70 and 80 per cent. But it is worth pointing out that with this amount of saltpetre, rockets will not function properly because the mixture becomes too explosive. Thus a wide variety of gunpowder mixtures was used for fire-lances, eruptors, rockets and true guns - each mixture tailored specially for each weapon. And, of course, there were different types of poisonous gunpowder for use when the wind was right, and coloured gunpowders for signal flares.

The true gun was eventually developed in China at some time during the thirteenth century. A bronze hand gun from 1288 has been excavated at Heilunchiang Province in Manchuria. It is more than I foot long and weighs 8 pounds. The gunpowder chamber has a small touch-hole for ignition; the bore is even. The explosion chamber is strengthened by a bulbous enlargement of the barrel at that point, which was a common feature of early guns to prevent them from splitting under the force of their own internal explosions.

For such a perfect little gun to exist in 1288, how long had guns existed prior to that date? The fact is, new inventions did not at once attract new words; at first a gun was hardly different from a fire-lance, so the same word was used for both weapons. It is safe to presume that guns

evolved around 1250, at the latest around 1280.

When did guns reach Europe? The earliest evidence is a picture of a bombard (a small bulbous cannon with a constant bore) which fired arrows, depicted in a 1327 manuscript by Walter de Milamete's On the Majesty, Wisdom, and Prudence of Kings, in the Bodleian Library at Oxford. Whereas it took 450 years for the firelance to reach Europe from China, the true gun did so in a tenth of that time.

How were these things transmitted? Needham believes it is quite likely that gunpowder in the form of fire-crackers reached Roger Bacon in England in 1265 through his friend the Franciscan William Ruysbroeck, who returned from China in 1256. Alternatively, Chinese evidence exists of a mission to the emperor by Scandinavian trader-envoys who reached China in 1261, several years before Marco Polo, apparently having travelled overland through what was then the independent kingdom of Novgorod.

After 1260, many foreigners were welcomed and employed by the Mongol emperors in China. It was their policy to treat the native Chinese as third-class citizens, hardly even regarding them as human. The Mongols did not trust the Chinese to run things, and tried to create a civil service of Mongols, Europeans and Arabs. With these constant foreign visitations, the transmission of guns to Europe was inevitable. Indeed, the writer Miu Yu-Sun quotes an obscure scholar, Yü Wei, as saying that in the second half of the thirteenth century a Mongol, Ch'i Wu Wen, went to Europe and took with him a complete knowledge of gunpowder technology and gunnery.

The similarities between the earliest European eruptors and cannons and the slightly earlier Chinese ones are so striking that it seems likely that actual guns were transported to

LEFT (185) A pivoting nineteenth-century breech-loading Chinese mortar gun of cast iron, with a wooden stock. The total length of this weapon is 8 feet. This type of gun was used for the defence of fortifications, and was not carried in the field. It was probably seized by British forces during the nineteenth-century conflicts in China and carried home as a specimen. (The Royal Armouries, Tower of London.)

LEFT (186) A fourteenthcentury cast iron Chinese cannon. The cannon length is 18.7 inches, the bore length is 16.1 inches, and the calibre 4.15 inches. (Royal Artillery Institution, Woolwich.)

Europe for direct copying. For instance, the earliest piece of field artillery we know of in China was on four wheels and called the 'thousand-ball thunder cannon'. It no longer had a bulbous body round the explosion chamber, and was ringed by bands of iron. A surviving woodcut from an old Chinese book shows that it was virtually identical to an early European field artillery piece portrayed in a German manuscript of about 1450. The German cannon was probably a direct copy, or it might even have been an obsolete Chinese model sold by some corrupt official to a Dutch trader.

Chinese fire-lances and eruptors did not fit the description of true guns as having a constant bore and a smoothly fitting projectile of exactly the right size. But between 1250 and 1280, the Chinese finally did achieve the manufacture of true guns, and by the 1320s these had reached Europe.

The evolution of guns and cannons proceeded apace in China, where perfectly cast iron cannons were being produced before Europe had even learned how to make cast iron (see page 44). The bulbous reinforcing of the barrel was superseded by even barrels along the whole length, while iron bands encircling the barrels provided reinforcement. These grew and flattened out as development proceeded, so that eventually the barrels were more than half covered by large flattened bands. Cannons commonly bore inscriptions, like crossbow trigger mechanisms, giving their precise dates of manufacture. There are literally hundreds of

medieval Chinese cannons still in existence today.

Projectiles also survive: rounded stones or carefully cast bronze or iron balls, and exploding cast-iron 'thundercrash' bombs (described at length on page 258). Bags of shot which smoothly fitted the bore could also be fired, as in the shotguns of today. While some of the cannons were laid flat, others were set at an angle and lobbed projectiles over, acting as mortars. As metallurgy developed, cannons became larger, longer and heavier. We read in *The Fire-Drake Artillery Manual* (1412) of a cannon which weighed 159 pounds; it was called the 'long-range awe-inspiring cannon':

Each weighs 72 kilograms [159 pounds] and measures 2 feet 8 inches long. The touch-hole is 5 inches from the base and 3.2 inches from where the belly begins. The diameter of the bore at the muzzle is more than 2.2 inches. Above the touch-hole there is a movable lid to protect the priming powder from rain. This cannon does not give a great bang or much recoil. With 8 ounces of gunpowder one uses one large lead ball weighing 1.2 kilograms (2.6 pounds), or a hundred small lead bullets in a bag, each weighing 0.6 ounces. Firing is done very conveniently by hand.

However, cannons grew in size from this until one weighing 1389 pounds, called 'the great invincible

general', was cast. A later giant cannon from the middle of the fifteenth century was the 'great general gun'. We have a description of this and of a later improved model:

Among the large firearms there is none that is greater than the 'great general gun'. Its barrel used to weigh 80 kilograms (176 pounds), and was attached to a stand made of bronze weighing 600 kilograms (1322 pounds).... Yeh Meng-Hsiung changed the weight of the gun to 150 kilograms (330 pounds) and doubled its length to 6 feet, but eliminated the stand, and now it is placed on a carriage with wheels. When fired it has a range of 800 paces. A large lead shell weighing 3.5 kilograms (7.7 pounds) is called a 'grandfather shell' and the next shell of medium size weighing 1.8 kilograms (3.9 pounds) is a 'son shell', while a smaller shell weighing 0.6 kilograms (1.3 pounds) is a 'grandson shell'. There are also 200 small bullets each weighing 0.3 to 0.2 ounces contained in the same shell and called 'grandchildren bullets', while the saying is that the 'grandfather' leads the way and the 'grandchildren' follow. They are supplemented with iron and porcelain fragments previously boiled in cantharides beetle poison. The total weight of the projectile is some 12

kilograms (26 pounds). A single shot has the power of a thunderbolt, causing several hundred casualties among men and horses. If thousands, or tens of thousands, of this weapon were placed in position along the frontiers, and every one of them manned by soldiers well-trained to use them, then we should be invincible. This weapon is indeed the ultimate among all firearms. At first its heavy weight caused some doubt as to whether or not it was too cumbersome; but if it is transported on its carriage then it is suitable, irrespective of height, distance or difficulty of terrain. During the sixth year of the T'ien-Sun reign-period (1462) 1200 gun carriages were made.... During the first year of the Ch'eng-Hua reign-period (1465) 300 different 'great general guns' were manufactured and 500 carriages for cannons were made. This was an excellent strategy in using Chinese expertise to keep the barbarians under control.

Attempts to develop repeat-firing guns continued. The Chinese came up with a method of doubling the rate of fire with small cannons by developing something called the 'Mr Facing-Both-Ways' gun. It consisted of two small cannons whose rear ends joined together in one long barrel. The first one was

RIGHT (187) A detail from a previously unpublished photograph, taken by Ernst Boerschmann in about 1900, of an unidentified medieval basrelief. The figure on the right is holding a fire-lance from which an arrow is protruding. Many fire-lances shot arrows with poisoned tips, followed by several minutes' spurting of fire and flames. The earliest proto-guns to reach Europe fired arrows.

BELOW (188) Sixteenth-century Chinese mortars being fired. These vase-shaped mortars have a uniform bore inside, despite the bulge outside. These were called the 'flying, smashing and bursting bomb-cannons', and had fuses running to the touch-holes through bamboo tubes. They fired cast-iron

bombshells which, when they exploded, also showered the ground around with calthrops – nasty little metal objects covered in sharp, poison-tipped points, which would be trodden on by the enemy's men and horses.

| Chineston and horses | 3600 men and horses | 3600

fired, and then the barrel was quickly rotated so that the second one fired. We are told:

Immediately after firing the first gun the second is rotated into position and fired, each one being muzzle-loaded with a large stone projectile. If the gun is aimed at the hull of an enemy ship below the waterline, the cannon-balls shoot along the surface and smash its side into splinters. It is a very handy weapon.

A further step was the development of the 'cartwheel gun'. It had thirty-six barrels radiating from its centre like the spokes of a wheel. These guns were small enough that a single mule could carry two, one on each side of its pack. However, as some of the barrels pointed at the gunner, there must have been some nasty accidents, so these 36-repeaters were never widely adopted.

Batteries of true guns were used, just as batteries of fire-lances had been. For instance, there was a 'nine ox-jar battery' with nine cannons resting together on a frame and fired by one fuse. Guns were also wheeled around on wheelbarrows. As the centuries wore on, cannons became more and more important in Chinese warfare, and huge artillery duels took place of a kind with which Europeans are well familiar. And handheld guns proliferated even more.

In the fifteenth century a single battalion of a Chinese army was provided with 40 cannon batteries, 3600 'thunder-bolt shells', 160 'wine-cup muzzle general cannons', 200 large and 328 small 'continuous bullet cannons' firing grape-shot, 624 hand guns, 300 small grenades, some 6.97 tons of gunpowder and no less than 1,051,600 bullets, each of 0.8 ounces.

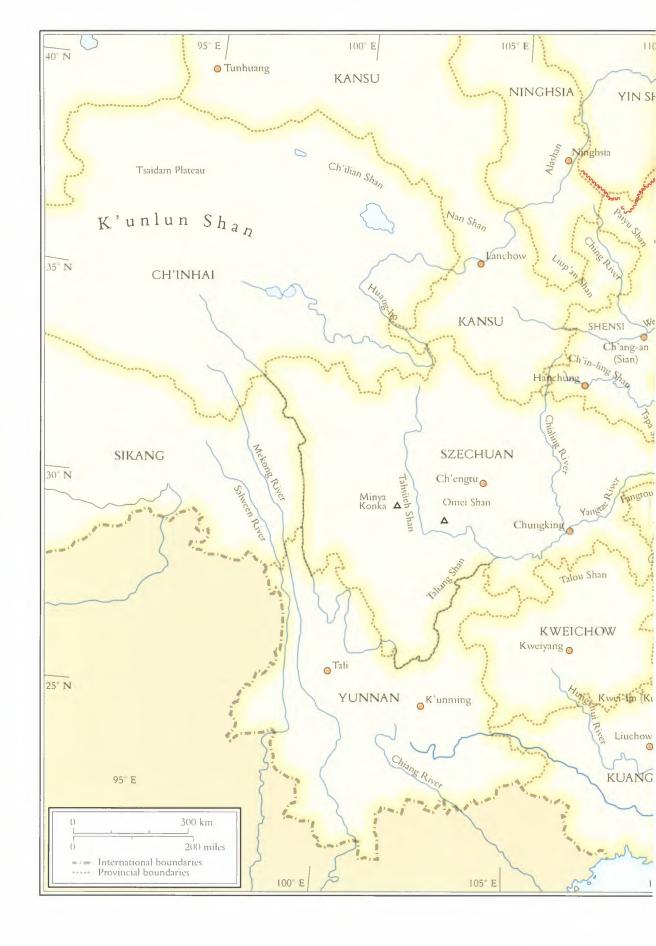

Needham remarks: 'This was quite some firepower, and the total weight of the weaponry was reckoned to be 29.4 tons.'

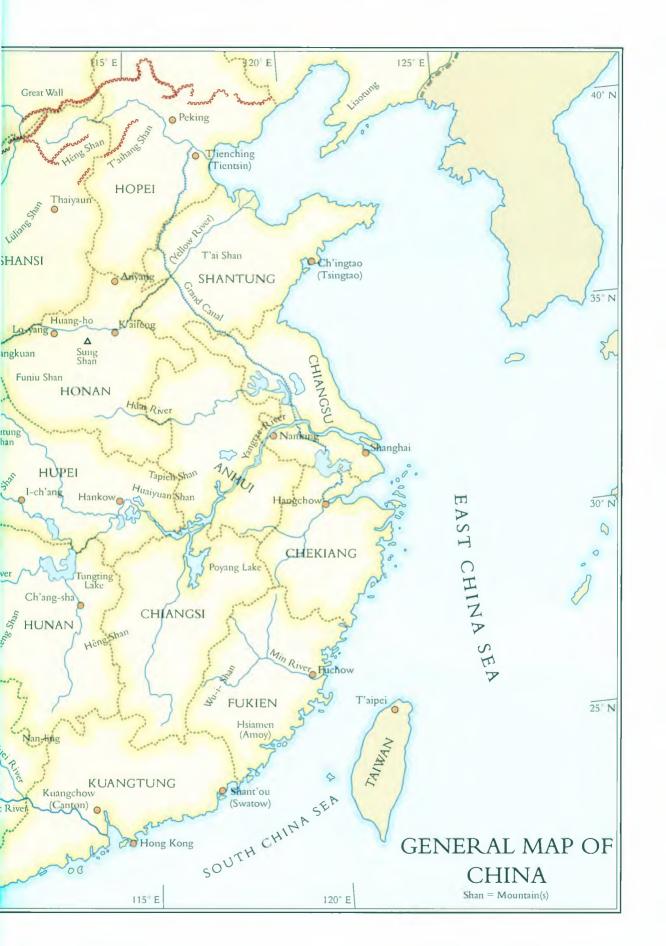

The vast quantities of weapons used and the enormous numbers of deaths which resulted make European war-death statistics before the nineteenth century seem puny. It is important to realize that Chinese armies commonly numbered hundreds of thousands at a time. By contrast, the English Civil War of the seventeenth century was fought by only a few thousand people, and if casualties for a single battle mounted into the hundreds it was considered horrific.

Indeed, the mass-production of armaments in medieval China rivaled the output of twentieth-century Detroit with its assembly lines of automobiles; division of labour and assembly-line techniques of producing crossbows, guns, gunpowder, porcelain, and all manner of commodities, both helpful and harmful, were traditional for centuries. The 'military-industrial complex', entirely state-run, with stringent security and highly classified new weapons projects, is a twothousand-year-old phenomenon in China. The Chinese were as expert at killing people as they were at inventing beneficial things; they were arms manufacturers on a scale undreamed of until modern times in the West. The Chinese inventive genius certainly did not hold back in pacifist timidity from the design and manufacture of weapons. No nation in the world could match the Chinese expertise in warfare for two millennia.

## **AUTHOR'S ACKNOWLEDGEMENTS**

My deepest debt of gratitude is owed to the late Dr Joseph Needham who authorised me to popularize his great work Science and Civilisation in China, in its published and unpublished sections. as well as all of his related writings. He threw open to me the magnificent facilities of what was then called the East Asian History of Science Library on Brooklands Avenue in Cambridge, which later moved its premises and became the Needham Research Institute, adjoining the grounds of Robinson College, in Cambridge. He extended to me hospitality, assistance and advice, as well as access to all necessary materials, including manuscripts of his. I am also deeply grateful to Dr Needham's second wife and closest associate, the late Dr Lu Gwei-Djen, who persuaded Joseph to agree to this project by pointing out to him that although he had always dreamed of doing this job himself, and had first publicly announced his intention to do so as early as 1946, he was too old (in his 80s) to carry it out and too burdened with other work. It was with the greatest sadness that Joseph relinquished his cherished dream of doing this book for the ordinary reading public himself, and allowed me to do it for him. His praise at the end of the task was my sufficient reward. Gwei-Djen was enthusiastically friendly and supportive to me at every turn, and her warm friendship and good will can never be forgotten. I was the only Western colleague of Joseph's who ever travelled to China with him. It was to be Joseph's last trip and my first. We had so many remarkable adventures together! Most amazing of all were our forays into the remotest areas of Chinese countryside, which has such overwhelming natural beauty. Anyone who has been to its truly hidden regions is forever touched by the exquisite and haunting mystery of China, which is unfathomable and infinite.

The book would not have been possible without the friendship and assistance of the remarkable Miss Carmen Lee, who was at that time the Librarian of the Library (later the Institute). She worked tirelessly on difficult problems as they arose, calling my attention to, or locating, obscure materials, and being generally supportive by her unflagging enthusiasm.

Dr Simon Mitton of the Cambridge University Press expedited and assisted this project in every way which was within his power, in a most generous manner.

Of Joseph Needham's collaborators who have helped me, I am most grateful of all to Dr H. T. Huang (Huang Hsing-Tsung). He made possible my entry 'Strong Beer' from an oral interview with him and vetted my account in person, allowing it to appear in print before he had even written his own first draft on the subject, which is true scholarly generosity. He also brought to my attention his subject of Biological Pest Control when it was still in proof stage. My next debt of gratitude is owed to Dr James C. Y. Watt, who cleared up many deeply confusing issues for my entry on porcelain (about which Joseph never wrote a word himself), and whose redrafting of

my initial two paragraphs I have largely adopted. Without his help, clarity would never have been attained in this highly specialized subject. Mr Edward McEwen was most helpful and generous on information about the crossbow, as was Dr Robin D. S. Yates about the stirrup (he was also the one who sent Joseph, Gwei-Djen and myself to the depths of Szechuan Province to see the oldest depiction of a gun which appears in Plate 168 (page 251), as he was the first to notice it). Others of the collaborators who were of some assistance were Dr Francesca Bray, Mr Kenneth Robinson and Professor T. H. Hsien (Ch'ien Ts'un-Hsün).

I am deeply grateful to Madame Chen Zhili, State Counsellor for Education, Science, Technology and Culture, in China, for writing her introduction to my book, and for taking such a keen interest in it and recommending it to the Chinese secondary school system when she was Minister of Education.

My gratitude to my old friend Dr Song Jian, former State Counsellor, and former Minister of Science and Technology, may be seen from my dedicating this edition of my book to him. His brilliant work as a scientist before he became a minister was entirely within the finest Chinese tradition of invention.

I am grateful to Christer von der Burg and Therese O'Connor for locating books and making helpful suggestions; and to David Goddard for his invitation to sail on and study his Chinese junk, Keying II, and for information and demonstrations about how steer and sail it. I am grateful to Dr Larry Schulz for going out of his way to take a photograph in China, and to Professor Melvin Kranzberg for putting me in touch with Dr Schulz and for helpful comments. I am also grateful to Lindsay Badenoch and Mrs You-Hsien (Isabella) Lewis, and extremely grateful to Graham Hutt of the Chinese Department of the British Library, for his generosity and help.

For many of the photographs I am indebted out of the ordinary to the extraordinary Miss Charlotte Deane, for her enthusiastic and devoted picture research, which on many occasions involved her in situations of unprecedented difficulty. Her tireless efforts on behalf of this project went beyond the call of duty. I am also uniquely indebted to Ulrich P. Hausmann for an enormous amount of help given out of a delightful enthusiasm he has for all matters Chinese. He has provided me with information, loaned me precious books, and resourcefully produced several magnificent photos for this book.

I would like to give special thanks to Michael Lee, who brought his uncanny expertise to bear on scanning illustrations and making the 'impossible' ones reproducible, such as Plate 156 (page 225), and cleverly joining up old Chinese engravings which were split into two halves, so that they now appear to be one image. He also found ways to scan large pictures, hangings, and rubbings, and they came out looking perfect (as may be seen in Plate 143 (page 208–9). For his efforts, he has been given the honorific Chinese name Li Mihai, and elevated to the Taoist pantheon.

I especially wish to acknowledge information which I have obtained from four particularly useful sources: an article on porcelain

by Hung Kuang-chu, the article 'The Chinese Cosnic Magic Known as Watching for the Ethers' by Derk Bodde, the book *The Vermilion Bird* by Edward H. Schafer (where additional information about the Magic Canal was found), and the article 'Porcelain and Plutonism' by Cyril S. Smith.

I wish most profusely to thank my secretary in Beijing, Miss Zhang Jing, for her tireless and determined efforts to assist me in this project over a long period, gathering material and making translations. She always shows ingenuity and rapidity in everything she does. I also wish to thank our mutual friend Du Xiansheng for his inspired and intelligent assistance over the years., and my old friend Professor Pan Jixing for valuable discussions and suggestions, and generous exchange of publications.

I wish to thank Miranda West, formerly of Andre Deutsch, and Gareth Jones and Steve Behan of Andre Deutsch for their wonderful editorial and photographic efforts respectively on this edition. I also wish to acknowledge also the magnificent design work of Clare Baggaley and Michelle Pickering.

I wish to thank the People's Educational Press in Beijing for their meticulous attention to detail in gathering from a wide variety of specialist scholars all over China a number of minor corrections to dates and names for the Chinese edition, which have duly been incorporated in this new English edition, in order to perfect its accuracy in every detail. In particular I wish to thank President Han Shaoxiang of P.E.P., Wei Guodong, Editor-in-chief, Chen Chen, Wang Cunzhi and Deng Wenfeng. I also wish to thank all the scholars throughout China who contributed to those corrections, and Professor Wang Cuncheng of Tsinghua University, who was in charge of this difficult and comprehensive project, and did such an excellent of coordinating it. I also wish to

earlier work on my book. I have left it to last to offer my fondest thanks of all to my wife, Olivia - not only for her general support at all times and in all circumstances, but also for her customary editing of everything written in this book, as in all my other books. She is the most brilliant editor I have ever known, and there is not a paragraph that she has not improved. She advises on and takes an interest in everything that concerns my work,

and was especially

active on this project.

thank Professor Chen Yangzheng for his
